- 12. (c) Brown fat contains fat cells with several small fat globules. Brown colour is due to iron-containing cytochrome pigment in fat.
- 13. (a) Moist surface of buccal cavity Stratified non-keratinised squamous epithelium
 Inner surface of bronchioles Ciliated epithelium
 Inner lining of salivary ducts Cuboidal epithelium.
- 18. (c) Nucleus of granulocytes is irregular and divided into 2-5 interconnected lobes. Hence these are also called polymorphonuclear leucocytes.
- 20. (b) Main haemopoietic organ in embryonic stage is liver. Other haemopoietic organ during foetal life – yolk sac, spleen, lymphnodes, red bone marrow.
- 21. (c) During blood clotting injured tissue or platelets release a lipoprotein factor called thromboplastin. Thromboplastin helps in the formation of the enzyme thrombokinase.
- 22. (b) Lymph has no RBCs but about 99% are lymphocytes usually of the small type, the remaining 1% is made up of leucocytes.
- 23. (c) All fasciculi of a muscle are bound together by a connective tissue termed perimycium which also forms a sheath around each fascicule.
- 24. (a) Each resting cell is in a polarized across its membrane called resting membrane potential. This potential averages 70 mv (– 60 to 90 mv) on inner side of the membrane in respect to its outer side.
- 25. (a) Biceps and triceps work as antagonistic muscles at elbow. Contraction of biceps and relaxation of triceps causes flexion of arm. Similarly, contraction of triceps causes extension of arm at elbow.

Assertion and Reason

- 1. (d) Total count of RBC refers to the total number of red blood corpuscles (erythrocytes) present in one microlitre of the blood. It average 5 million and 4.5 million in adult man and woman respectively. Total count of RBC comes out to be very low in condition of anaemia and after profuse bleeding. On the contrary, polycythemia is the condition which arises due to the abnormal rise in the total count of RBC.
- 2. (c) Conjugated proteins are the proteins which are formed by the binding of a simple protein with a non-protein prosthetic group. Conjugated chromoproteins are the pigment protein complexes. Haemoglobin is one such conjugated chromoprotein. It is composed of a simple protein called "globin" and non protein iron (Fe²⁺) porphyrin complex called "heme". 100 ml of blood contains about 15g of haemoglobin. Four Fe²⁺ ions of heme can loosely bound to upto four molecules of oxygen, thus enabling haemoglobin to carry oxygen.
- 3. (a) Histamine is a derivative of the amino acid histidine produced by damaged cells of vertebrates. When released, it has the effect of dilating capillaries and lowering blood pressure. Histamine is involved in allergic and inflammatory reactions.
- 4. (e) Treating the blood to low temperatures (chilling) decreases the activity of coagulation promoting enzymes. So, at low temperatures it will take more time for the blood to clot i.e. the coagulation of blood gets delayed. Thus chilling of blood increases the coagulation time (time taken for the blood to coagulate) and not decrease it.
- 5. (c) Blood coagulation is brought about by the hydrolysis of soluble protein fibrinogen to insoluble fibrin. This reaction is catalysed by the enzyme thrombin. Thrombin occurs in normal blood as an inactive globulin called prothrombin which is activated to thrombin by the action of another enzyme called prothrombinase before blood coagulation starts. Thromboplastins are the coagulation promoting substances released from clumped platelets and damaged tissue, which helps in the formation of the enzyme prothrombinase.
- 6. (a) The symptoms of an allergic reaction develop in response to histamine. Mast cells release a large amount of histamine into the blood stream and it also act as initiator of the inflammatory response which aids the arival of leucocytes at a site of infection. Histamine stimulates capillary dilation, increased capillary permeability, closure of bronchial tubes, mucus secretion, pain and swelling.

- 7. (e) Regulation of RBCs production is accomplished by hormone erythropoietin which is secreted by kidney. This hormone increases stem cell mitosis and speed up RBC's development in red bone marrow.
- 8. (e) Since muscle cells are very thin and elongated, therefore, they are also called as muscle fibres and not myofibril. Myofibril is the unit of a striated muscle fibre. A striated muscle fibre is composed of many myofibrils arranged along the long axis of the fibre. A myofibril is of two types of myofilaments-actin filaments and myosin filaments. Sliding of these myofilaments over one another cause the contraction and relaxation of the muscle fibre.
- 9. (b) The thigh muscles are the striated muscles which soon get fatigued due to overwork. These muscles show fast contractions and then tire immediately due to accumulation of lactic acid. The muscles of heart wall, are the cardiac muscles which are unfatiguable and show rhythmic and automatic contractions. They have specialised regions of the cell membranes which function as boosters for muscle contraction waves. Thigh muscles are called voluntary muscles because they can be moved at the will of organism whereas heart muscles can't be moved at one's will and therefore are involuntary.
- 10. (b) In wounds, germs are removed by WBCs accumulation at wound site by diapedesis. It is squeezing of leucocytes out from endothelium of capillaries to fight external agent.
- 11. (d) Non striated or smooth muscles are said to be involuntary in nature because they do not contract or relax according to our will. Those muscles which can be moved according to will of the organism are called voluntary muscles. Striated or skeletal muscles are said to be voluntary in nature as they can be contracted or relaxed voluntarily.
- 12. (a) Cardiac muscle cells are short cylindrical cells joined end to end and by side branching to form a network. Intercalated discs are the dense junctions formed in between the cardiac muscle cells where they meet each other. Intercalated discs are the specialised regions of the cell membranes. As cardiac muscle possesses considerable rhythmicity and generates its own wave of excitation, these discs function as boosters for muscle contraction wave.
- 13. (d) Ordinary connective tissue is absent inside the central nervous system. i.e. brain and spinal cord and has no function in the conduction of nerve impulse. The neurons of nerve tissue inside the brain and spinal cord are held together by supporting cells called neuroglia cells. Neuroglia cells resemble neurons and have long radiating processes but no nissl granules.

- (a) Histamines are involved in allergic and inflammatory reactions. Histamines also dilate capillaries.
- 15. (c) Myelin sheath is a lipid rich insulating layer which covers some nerve fibres of nerve tissue. Such fibres are called myelinated or medullated nerve fibres. Each myelinated nerve fibre shows constrictions at regular intervals called nodes of Ranvier which results from interruption in the myelin sheath at those places. Non myelinated nerve fibres are not covered by any myelin sheath, consequently no nodes of Ranvier are present in them.
- 16. (a) Specialization of cells into tissue, organ and organ systems is advantageous for the organism. It increase the operational efficiency through division of labour which avoids duplication of work.
- 17. (b) Cartilage comprises of mucopolysacharide called chondroitin sulphate. Bone is a hard connective tissue. Blood is a fluid connective tissue.
- 18. (e) Though blood vessels are absent in epithelial tissues, exchanges of materials takes place in them. Materials are exchanged between epithelial cells and vessels of the connective tissues by diffusion across the basement membrane. Also through osmosis and filtration, epithelial tissues exchange materials (e.g. epithelial tissues of pulmonary vein, Bowman's capsule etc).
- 19. (a) The columnar epithelium bearing microvilli on their free ends give a brush-like appearance to these free border. Villus shaped microvilli greatly increase the area of the free surface of the cell and thereby enhance absorption. Lining of gall bladder, stomach, large intestine are the example of columnar epithelium.
- 20. (e) Fatigue is the inability of a muscle to contract. It is due to depletion of its chemicals and lactic acid accumulation by repeated contraction.
- 21. (a) Fibroblasts are the principal cells of areolar tissue. Fibroblasts synthesize two kinds of proteins-collagen and elastin. The tensile strength of collagen fibres and the elasticity fibres prevent displacement and injury of tissues and organs under mechanical stress. Collagen fibres are also laid down at sites of injury and help in tissue repair.
- 22. (d) Lacunae are actually the flat irregular spaces occurring in the solid matrix of bone. Each lacuna lodges a flat bone cell or osteocyte. Compact bone possesses many parallel, longitudinal column like structures called haversian systems, in which several concentric layers of bony matrix called lamellae encircle a longitudinal central canal called haversian canal. It is the Haversian canal, which carries blood vessels and nerves to the bone. Lacunae containing osteocytes occur in a layer between two lamellae.
- 23. (e) Keratinised stratified squamous epithelium is a compound epithelium which covers the dry surface of skin. It has many layers of epithelial cells. The deeper layers are formed by living polygonal cells but superficial layers constitute of horny, scale like remains of dead squamous cells. Heavy deposits of the insoluble protein keratin in the dead superficial cells make the epithelium impervious to water and highly resistant to mechanical abrasions.

- 24. (a) Extracellular materials (also called Intercellular materials) are very important for cells because they surround the individual cells, separate them from each other and bind them together. One or more types of specialized cells are set in specific extracellular materials to constitute a tissue. Nature and amount of extracellular material vary from tissue to tissue. In some tissues, it is limited to very thin layers whereas, in some it is quite vast and separates cells widely apart from one another.
- 25. (d) Simple epithelium doesn't cover surfaces exposed to mechanical or chemical abrasions, because it is made up of a single layer of cells, hence it is not effective in protecting the underlying tissue. Simple epithelium occurs mainly on secretory and absorptive surfaces. There is another types of epithelial tissue called compound epithelium which being multilayered is effective in providing protection to underlying tissues, hence covers the surfaces exposed to mechanical and chemical abrasions.
- 26. (d) It is not tendon but another type of connective tissue called ligament which is present in most of the bone joints and connect the bones together. Ligament also helps in holding the bones in position. Tendon, on the other hand, is a dense, strong, fibrous connective tissue which forms strong inextensible attachment of a skeletal muscle to a bone.
- 27. (c) Urinary bladder is not lined by squamous epithelium but by transitional epithelium which is a stretchable compound epithelium. It has a single layer of cuboidal cells at the base, 2-3 middle layers of large polygonal cells and a superficial layer of large, broad rectangular cells. Stretching considerably flattens and broadens the cells of superficial and middle layers, hence causing expansion of the urinary bladder.
- 28. (b) On the basis of presence of tiny granules and number of lobes in nucleus of their cytoplasm, white blood cells are divided into two groups
 - Granulocytes Contain tiny granules and lobed nuclei in their cytoplasm.
 - (ii) Agranulocytes Have no cytoplasmic granules in their cytoplasm and their nuclei are also undivided.
- 29. (a) Columnar epithelium is a type of simple epithelium characterised by the presence of tall column like cells. Its major function is absorption or secretion. It covers the inner surface of the intestine, stomach and gall bladder. In the intestine it appears to have a brush like appearance on the free surface, which is due to the presence of large number of microvilli. Function of microvilli is to enhance absorption. Due to the presence of microvilli, the epithelium is also called as brush bordered columnar epithelium.
- 30. (a) The regulation of RBC production is accompanied by the hormone erythropoietin, which is secreted by the juxtaglomerular cells of kidney. This hormone circulates to the red bone marrow, where it increases stem cell mitosis and speeds the development of RBC.

FT Self Evaluation Test

Which one of the following is wrongly matched

[Kerala PMT 2009]

- Contractile protein (a) Myosin (b) Tendon Connective tissue
- (c) Smooth muscle Involuntary muscle
- Myoglobin (d) Red muscle
- (e) Troponin Fibrous protein
- Pseudostratified epithelium is always 2.

[DPMT 1993]

- (a) Single layered
- (b) Double layered
- (c) Multilayered
- (d) Uncertain
- Find the wrongly matched pair

 - (a) Unicellular glandular cells Goblet cell
 - Exocrine secretion
 - (c) Fusiform fibres Smooth muscle
 - (d) Cartilage Areolar tissue
 - (e) Intercalated discs - Cardiac tissue
- The epithelial lining the alveoli of the frog's lungs facing lung [BHU 2008]
 - (a) Columnar, non-ciliated (b) Columnar, ciliated
 - (c) Squamous, ciliated
- (d) Squamous, non-ciliated
- Epithelial cells adhere to one another with considerable 5. [BHU 2005] force due to
 - (a) Intercellular attraction
- (b) Presence of desmosomes
- (c) Both the above
- (d) None of the above
- Basement membrane is made up of [CBSE PMT 1997]
 - (a) Epidermal cell only
 - (b) Endodermal cell
 - (c) No cell product of epithelial cell
 - (d) Both (a) and (b)
- Transitional epithelium is found in [AFMC 1997]
 - (a) Lungs
- (b) Liver
- (c) Urinary bladder
- (d) Stomach
- 8. The term "blubber" refers to [KCET 1994]
 - (a) A substitute for natural rubber
 - (b) A subcutaneous deposition of fat in whales
 - (c) The irregular heart-beat sound
 - (d) None of these
- Fats are richly found in

[NCERT:

MP PMT 1994, 2003; Pb. PMT 1999]

- (a) Alveolar tissue
- (b) Lymph glands
- (c) Adipose tissue
- (d) Liver cells

In the diagram of the section of bone tissue given below, 10. certain parts have been indicated by alphabets; choose the answer in which these alphabets have been correctly matched with the parts which they indicate [KCET 2001]

- (a) A = Interstitial lamellae, B = Lacuna with osteocytes, C = Blood vessels, D = Nerve, E = Canaliculi, F = Haversian canal, G = Lamellae
- (b) A = Interstitial lamellae, B = Osteocytes in the lacuna C = Blood vessels, D = Nerve, E = Lamellae, F = Haversian system, G = Canaliculi
- (c) A = Lamellae, B = Lacuna with osteocytes, C = Artery, D = Lymphatic vessels, E = Canaliculi, F = Vein, G = Haversian canal
- (d) A = Interstitial lamellae, B = Osteocytes, C = Nerve, D = Blood vessel, E = Lamellae, F = Haversian canal, G = Canaliculi
- Vertebrate nails are derivatives of

- (a) Stratum lucidum (b) Stratum germinatirum
- (c) Stratum granulosum (d) Stratum corneum
- Shivering in cold is a method for
 - (a) Prevention of radiation of heat from the body
 - (b) Production of healthy muscle friction
 - (c) Production of heat by muscular contractions

- (d) $B \rightarrow D \rightarrow C \rightarrow F \rightarrow G \rightarrow A$

- 15. Which is not true for Red Fibres [NCERT; MP PMT 2011]
 - (a) Muscle contains a red coloured oxygen storing pigment
 - (b) Muscle contains plenty of Mitochondria
 - (c) These muscles also called aerobic muscles
 - (d) Amount of Sarcoplasmic reticulum is high in it
- 16. Concave surface of mammalian R.B.Cs is helpful in
 - (a) Formation of more haemoglobin
 - (b) Increasing surface area of R.B.Cs
 - (c) Reducing surface tension of plasma membrane
 - (d) Providing more space for haemoglobin
- 17. Muscles of alimentary canal are chiefly [MP PMT 2001]
 - (a) Striated and Neurogenic (b) Unstriated and Neurogenic
 - (c) Striated and Myogenic (d) Unstriated and Myogenic
- 18. Which is the principal cation in the plasma of the blood
 [CBSE PMT 1999]
 - (a) Calcium
- (b) Sodium
- (c) Potassium
- (d) Magnesium
- 19. What will happen, if the ligaments are cut or broken

[CBSE PMT 2002]

- (a) No movement at joint
- (b) Bone will become unfix
- (c) Bone will become fixed
- (d) Bones will move freely at joints
- 20. Cardiac muscles are characteristic in that they contract
 - (a) Slowly and get fatigued
 - (b) Quickly and get fatigued
 - (c) Slowly and do not get fatigued
 - (d) Rhythmically and do not get fatigued
- 21. The outermost sheath of connective tissue that surrounds a skeletal muscle is [BHU 2002]
 - (a) Epimer
- (b) Epimere
- (c) Epimerite
- (d) Epimysium
- 22. Which of the following matches correctly [AIIMS 2009]
 - (a) Factor II Thromboplastin
 - (b) Factor III Prothrombin
 - (c) Factor VIII Antihaemophilic globulin
 - (d) Factor XII Haemophilic
- 23. Striped muscles are
- [MP PMT 1999]

- (a) Syncytial
- (b) Uninucleate
- (c) Binucleate
- (d) Anucleate
- 24. The % similarity in β -chain of Hb in man and rhesus monkey is [Odisha JEE 2004]
 - (a) 2%
- (b) 4%
- (c) 8%
- (d) 40%
- 25. Which of the following does not match
- [CPMT 2004]
- (a) Muscular movement-ATP
- (b) Heart-pace-maker
- (c) Monocyte-haemoglobin
- (d) Nerve impulse-acetylcholine
- 26. Difference between bone and cartilage is [RPMT 2005]
 - (a) Haversian canal
- (b) Blood vessel
- (c) Lymph vessel
- (d) All of these
- 27. Largest smooth muscle is present in
 - [AIIMS 1998; CPMT 2002; RPMT 2005]
 - (a) Leg
- (b) Thigh
- (c) Uterus of pregnant woman (d) Urethra
- 28. What percentage of CO2 is transported by RBC's
 - [MP PMT 2011]

- (a) 70%
- (b) 20 25%
- (c) 97%
- (d) 7%

Answers and Solutions

26	d	27	c	28	b	Both			

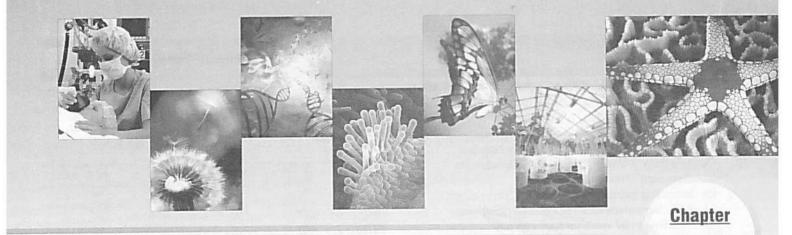

- 2. (a) The pseudostratified epithelium without being truly stratified appears to have 2 or 3 layers of cells as nuclei are present at two levels but actually it is single layered.
- 6. (c) Basement membrane is a delicate intercellular membrane visible in light microscope, which underlies most animal epithelia. Besides this, the basal lamina consists of mucopolysaccharide and very fine fibres.
- (c) Transitional epithelium is thin flexible and impermeable to water. It forms the inner layer of urinary bladder.
- 8. (b) Blubber is thick subcutaneous fat insulating body heat in aquatic mammals like whales.
- (c) The fat storage tissue is called adipose tissue, it is a connective tissue. It also forms shock proof cushions around the kidney, ovaries and eye ball.
- 12. (c) "Shivering with cold" in winter is caused by a quick involuntary reaction of striated muscles. It yields, not a mechanical work but only some heat just to warm the body.
- **13.** (a) Sesamoid bone is formed by the ossification of tendons e.g. patella.
- **14.** (b) Injury → Prothrombin → Thrombin

Fibrinogen —

Thromboplastin $\leftarrow \frac{Ca^{2+} \text{ ions}}{}$ \longrightarrow Blood clot.

So, option (b) is correct.

- 16. (d) Due to the absence of nucleus, mammalian R.B.Cs become biconcave shape which help to accomodate maximum amount of haemoglobin.
- 17. (d) Muscles of the gut wall are innervated by autonomic nerve fibres and are self-excitatory.
- (b) Plasma is extracellular fluid. Na⁺ is the principal mineral cation in the extracellular fluid.
- 20. (d) Cardiac muscles have mixture of properties of both striated and unstriated muscles. These muscles continue rhythmic contraction throughout life under the control of A.N.S.
- (a) A striped muscle fibre has many nuclei and it is a syncytium (coenocyte).
- 25. (c) Monocyte is the largest white blood cells (WBCs) whereas haemoglobin is found in R.B.Cs. Thus monocyte is not correctly matched with haemoglobin.

Morphology of Animals

2.4

RANA TIGRINA (The Common Indian Frog)

Systematic position

Phylum - Chordata

Sub phylum - Vertebrata or Craniata

Class - Amphibia

Order - Salientia or Anura

Genus – Rana Species – tigrina

Habitat

Rana tigrina is the most widely distributed species in Northern India. Generally frogs are found in ponds, tank, pools, ditches, etc. However, they may leave their aquatic habitat to come on land to hunt for their prey, which are mostly insects.

Habits

- (1) Locomotion: (a) Jumping and leaping, (b) Swimming. Absence of neck is helpful in swimming in water and jumping on land
- (2) **Feeding**: The adult frog is carnivorous. Tadpole (larva of frog) is herbivorous.
- (3) Croaking: The male frog croaks louder than the females because of the presence of two vocal sacs in male frog. The vocal sacs act as resonators. The croaking is mating call to attract the female frog.
- (4) **Hibernation (Winter sleep)**: During hibernation frog respires through skin (cutaneous respiration) only.
- (5) Aestivation (Summer sleep): During this period frog takes rest in shady, cool and moist place and recuperates its energy.

- (6) Protective Colouration: The frog is capable of changing its body colour with change in its surroundings. It can not only avoid its enemies but can catch its prey unnoticed.
- (7) Breeding: The male frog jumps on the female frog and holds her tightly with the help of his fore-limbs. Gripping of the female by the male is also very much aided by the presence of nuptial pads. This sexual embrace is called the amplexus. Fertilization is external. During development, a fish like tailed tadpole is produced, which respires with the help of gills and feeds upon vegetable matter.
- (8) **Moulting:** The frog sheds off almost once a month its skin during its active life in the form of small casting. This phenomenon is known as moulting or ecdysis.

External morphology

The dorsal surface of frog is spotted olive green and ventral pale yellow; this protective colouration help to camouflage, i.e. escape the detection by enemies.

Body division: The body of frog has two main divisions head and trunk; absence of neck and tail helps both in jumping on land and swimming in water.

- (1) Head: Head is anterior flattened triangular part with, a wide transverse terminal mouth, a pair of small dorsal external nares, two dorso-lateral eyes, a mid-dorsal light coloured brow spot or third eye or pineal body and obliquely placed pigmented circular tympanum or ear drum. Eyes are provided with nictitating membrane for protection.
- (2) Trunk: Trunk is the large, oval, flattened main part of the body. It is differentiated into hard anterior thorax and soft posterior abdomen. The trunk is provided with a pair of fore and hind limbs. The fore limbs are shorter and stouter, end in four digits thumb or pollex is absent. The hind limbs are much larger and muscular than the fore limbs, end in five digits.

Sexual dimorphism

The male and female frogs can be differentiated externally. The male frog possesses vocal sacs, which are most developed during the breeding season. During the breeding season an amplexusory or nuptial pad is developed on first finger of each hand of the male frog.

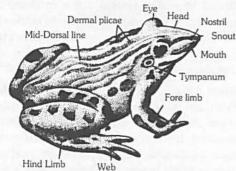

Fig: 2.4-1 External morphology of frog

Internal morphology Skin (Integument)

Histologically, the skin consists of outer epidermis and inner dermis.

- (1) **Epidermis :** Epidermis is ectodermal in origin and is made up of stratified squamous epithelium. It consists of stratum germinativum (S. malpighi), S. spinosum, S. granulosum, S. lucidum and S. corneum (horny layer). S. corneum is protective in function and is periodically cast off (moulting). This phenomenon, is known as ecdysis.
- (2) **Dermis**: It is punctured at places by ducts of cutaneous glands. Dermis is region of skin that lies below the epidermis. It has a loose connective tissue or stratum spongiosum on the outside and compact dense connective tissue or stratum compactum on the inner side. Stratum spongiosum has lymph spaces, nerve fibres, blood capillaries, mucous glands, poison glands, and chromatophores. Mucous glands secrete mucus which makes the skin moist and slippery. Chromatophores provide colouration to skin. They are of three types-melanophores (brownish black), lipophores (reddish and yellowish) and guanophores (whitish).

Digestive system

It consists of alimentary canal and digestive glands.

Alimentary canal: The alimentary canal of frog is a long and coiled tube with varying diameter extending between mouth and cloaca.

- (1) Mouth: The mouth is a terminal wide opening bounded by two bony jaws. Upper jaw is fixed while lower jaw can move up and down with the help of hinge joint.
- (2) **Buccopharyngeal cavity:** Teeth are present on premaxillae, maxillae of upper jaw and vomers of the roof of buccopharyngeal cavity. The lower jaw of frog is toothless. Teeth are homodont, acrodont and polyphyodont. These are not used for chewing instead they help to hold the prey. The tongue is large muscular, sticky, bilobed at the tip and free from behind and is used for capturing the prey. Frog has no salivary glands. Various apertures like opening of eustachian tube, vocal sac (only in male), gullet and glottis are present in the buccopharyngeal cavity.

- (3) Oesophagus: Because of the absence of neck in frog, the oesophagus is only a short tube. The oesophagus leads to the stomach.
- (4) **Stomach**: It is divisible into two parts. Cardiac stomach, the anterior larger part is present near the heart. The opening of the oesophagus into the cardiac stomach is guarded by a cardiac sphincter, a powerful narrow tapering part, which is separated from the duodenum by a muscular constriction, the pyloric constriction externally, which indicates the position of pyloric sphincter, which controls the entry of food into duodenum.
- (5) Small Intestine: It is the longest part of the alimentary canal suspended by mesentery, and is divisible into duodenum and ileum.
- (i) Duodenum: It is a 'U' shaped structure. It receives the hepatopancreatic duct from the liver and pancreas.
- (ii) **Ileum:** It is a narrow tube which is coiled in order to accommodate itself in a limited space. The internal lining of the ileum is thrown into a large number of finger like branched projections known as villi which increases the absorptive surface area.
- (6) Rectum (Large Intestine): Posteriorly, it opens into the cloaca through an aperture known as anus which is guarded by an anal-sphincter. The rectum stores the faecal matter and water is absorbed by its wall.
- (7) **Cloaca**: It is the last part of the alimentary canal, which receives the rectum in both the sexes, but in female frog, the cloaca also receives the ureters and oviducts, while in the male the urinogenital ducts are received in addition to the rectum.

The urinary bladder also opens into the cloaca. The cloaca opens out through a cloacal aperture.

Digestive glands

- (1) Liver: It is the largest gland of the body. It consists of three lobes-right, left and median. Liver secretes a greenish alkaline fluid bile, which is temporarily stored in gall bladder before being released into the duodenum. Bile helps in digestion of food by changing its pH from acidic to alkaline and by emulsifying the fat.
- (2) Pancreas: It is diffused creamish gland that lies in the loop between stomach and duodenum. It has lobules that secretes pancreatic juice. Pancreatic juice is alkaline. It contains amylolytic, proteolytic and lipolytic enzymes. Pancreatic juice is poured alongwith bile into duodenum through hepatopancreatic duct.
- (3) Gastric Glands: They secrete gastric juice having HCl and pepsinogen. Oesophagus also has glands which produce propepsin. Both propepsin and pepsinogen are changed into active pepsin.
- (4) Intestinal Glands: Their secretion is called intestinal juice or succus entericus. It contains enzymes peptidases, maltase, lipase, etc.

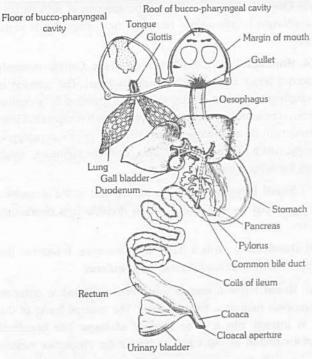

Fig: 2.4-2 The digestive system of frog

Respiratory system

Frog can perform respiration through three methodscutaneous, buccopharyngeal and pulmonary.

- (1) Cutaneous Respiration: Skin of Frog is thin and richly supplied with blood capillaries. It is kept moist by mucus and water. Oxygen from air diffuses into blood through moisture over the skin. CO_2 similarly, diffuses in the reverse direction from blood to air through moist surface of skin. Cutaneous respiration occurs in water, during hibernation and even aestivation. So it is the most vital mode of respiration .
- (2) Buccopharyngeal Respiration: Exchange of gases take place in the lining layer of buccopharyngeal cavity. Throat is raised and lowered alternately by petrohyal and sternohyal muscles respectively. This expels out foul air and brings in fresh air. Buccopharyngeal respiration is performed when oxygen requirement is less, during rest over land and while 'floating' in water.
- (3) Pulmonary Respiration: It occurs when oxygen demand is high. The rate is not more than 20/min. as compared to 80/min for buccopharyngeal respiration. Throat is lowered, air from outside enters buccopharyngeal cavity, it is called aspiration. Throat is raised, glottis opens and air passes into lungs through laryngotracheal chamber, it is called inspiration. Lungs are two ovoid pinkish elastic bags having a large number of small shallow chambers or alveoli. Blood capillaries overlie the epithelial lining of the alveoli. Exchange of gases occurs between air and blood capillaries. Lungs contract and foul air is pushed into buccopharyngeal cavity by lowering of throat. Throat is now raised, external nares opened and the foul air is passed out. The process is called expiration.

Laryngotracheal chamber

It is voice box of frog. Laryngotracheal chamber possesses two vocal cords, an opening of glottis into pharynx and bronchus

into lungs. It is supported by three cartilages, two arytenoid and one cricoid.

Circulatory system

The circulatory system of frog consists of blood vascular system and lymphatic system.

- (1) **Blood Vascular system**: It is of closed type as the blood flows in the blood vessels. It represents single circulation. It means both the oxygenated and the deoxygenated blood enters the heart and get mixed in the ventricle. Blood vascular system comprises blood, heart and blood vessels.
- (i) **Blood**: It is mobile connective tissue consisting of blood plasma (fluid) and blood corpuscles (cells). Three types of blood corpuscles are present in the plasma, viz, erythrocytes (RBCs-Red blood corpuscles), leucocytes (WBCs-white blood corpuscles) and thrombocytes-spindle cells. RBCs are nucleated, oval and biconvex and have haemoglobin (respiratory pigment). WBCs are amoeboid shaped and are protective in function. Thrombocytes are spindle shaped and help in blood clotting.
- (ii) **Heart**: The heart lies enclosed by a thin, transparent, two layered sac, pericardium. It is a three-chambered structure made of two upper auricles and a single lower ventricle. Two additional chambers connected to the heart of frog are sinus venosus and truncus arteriosus. Sinus venosus is a triangular chamber attached dorsally to heart formed by the union of three main vena cava. A short sac like truncus arteriosus is present on the ventral side of the heart over the larger right auricle. Truncus arteriosus is further divided into a long basal thick walled conus arteriosus or pylangium and a short distal thin walled bulbous aorta or synangium. A large twisted spiral valve further divides incompletely the cavity of pylangium into a left dorsal cavum pulmocutaneum and right ventral cavum aorticum. A definitely arranged network of arteries and veins forms the arterial and venous systems.

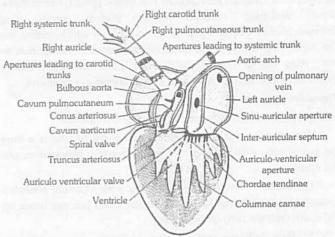

Fig: 2.4-3 Heart of frog

- (2) **Portal system :** In some vertebrates there is a characteristic arrangement where the veins does not directly take blood towards the heart but divides into a capillary set and supply the organ. This is known as portal system. In frog there are two portal systems
 - (i) Renal portal system
 - (ii) Hepatic portal system

Portal System:

- (i) Renal Portal System: A branch from femoral called femororenal combine with sciatic vein to form renal portal vein. It proceeds towards kidney of its side, receives a dorso-lumbar and then enters the kidneys breaking up into capillaries for quicker extraction of nitrogenous waste products and salt. The purified blood is then collected from the kidney by renal veins.
- (ii) **Hepatic Portal System**: It is formed of two veins, hepatic portal vein and anterior abdominal vein. Hepatic portal vein is formed by fusion of a number of veins from digestive tractrectal, intestinal, splenic, duodenopancreatic, gastric and oesophageal. Anterior abdominal is formed by the union of pelvic branches from femorals. It recieves vesicular vein from urinary bladder and a number of small veins from abdominal wall. Near liver it is joined to hepatic portal vein by a small branch. The two then enter liver, break up into capillaries for disposal of their contents. Purified blood is taken out by hepatic veins into postcaval.

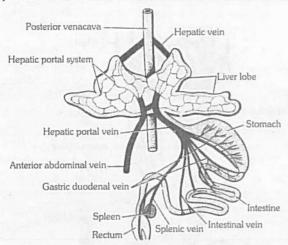

Fig: 2.4-4 Portal system of frog

(3) **Lymphatic system:** Lymph flows through the lymphatic system. Lymph is like blood but it is without RBCs and thrombocytes. It is colourless. Lymph acts as "middle man". In addition to the lymph, lymphatic system comprises lymph capillaries, (closed at the tip), lymph sinuses (spaces filled with lymph) and two pairs of lymph hearts. The flow of lymph is from the lymph capillaries → lymph sinuses → lymph hearts → veins.

Nervous system

The nervous system of frog is composed of central nervous system, peripheral nervous system and an autonomic nervous system.

- (1) Central nervous system: It comprises the brain and spinal cord. The brain is lodged in the skull, while spinal cord is enclosed by the vertebral column.
- (2) Peripheral nervous system: The nerves arising from the central nervous system constitute the peripheral nervous system. The nerves originate from the brain and spinal cord and are known as cranial nerves and spinal nerves respectively.
- (3) Autonomic nervous system: It includes the nerves and ganglia that control and coordinate such organs which are not under voluntary control. It comprises sympathetic nervous system and parasympathetic nervous system.

Brain: The brain is the anterior most part of the central nervous system. It is situated in the cranial cavity and is covered by

a delicate, pigmented and vascular membrane, the piamater. The cranial cavity is internally lined with a tough membrane, the duramater. The space in between duramater and piamater is filled with a shock absorbing cerebrospinal fluid. The brain is divided into forebrain, midbrain and hindbrain. The forebrain includes olfactory lobes, paired cerebral hemisphere and unpaired diencephalon. The mid brain, the broadest, bears dorsolaterally a pair of large rounded optic lobes (corpora bigemina). The hind brain consists of a poorly developed cerebellum and medulla oblongata. Medulla oblongata passes out through the foramen magnum and continues into spinal cord, which is contained in the neural canal of vertebral column.

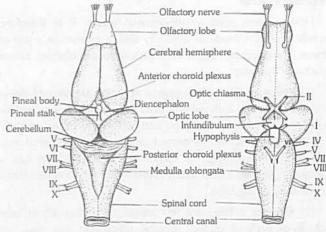

Fig: 2.4-5 Brain of frog, (a) Dorsal view, (b) Ventral view

Cranial nerves: The nerves which connect the brain and leave the brain box (cranium) are known as cranial nerves. The number of cranial nerves is definite in a particular group of animals. In frog, the number is ten pairs. The serial number of a nerve is also definite.

Sense organs

Sense organs receive stimuli (changes in the environment) from outside or inside of the animals and pass impulses to the nervous system. Frog has following five types of sense organs –

- (1) Tango-receptors (organs of touch): These are nerve endings and touch corpuscles which are found in the skin. Nerve ending are also present in the viscera (soft internal organs).
- (2) Olfacto-receptors (organs of smell): They are present in the nasal epithelium of the nasal chambers.
- (3) Gustato-receptors (organs of taste): These are found as taste buds which are present in the epithelium of the tongue and the buccopharyngeal cavity.
 - (4) Photo-receptors (organs of sight): Eyes.
- (5) Statoacoustic receptors (Hearing and balancing organs): Ears.

Out of these, eyes and internal ears are well organized structures and the rest are cellular aggregations around nerve ending. Eyes in a frog are a pair of large, spherical structures situated in the orbit in the dorsolateral side of head protected by eyelids. The eye ball is composed of three concentric layers, sclerotic, choroid and retina. The cornea is transparent and permit entry of light into the eye.

Ears are statoacoustic organs meant for equilibrium and hearing. Ear of frog consists of only two parts, middle and internal ears; external ear is absent. Tympanum is a dark, flat circular patch of skin found externally behind eye. Middle ear contains bony columella auris and cartilagenous stapedial plate, which passes vibrations to internal ear or membranous labyrinth.

Endocrine system

The chemical coordination of various organs of the body is done by hormones secreted by the endocrine glands. The important endocrine glands found in a frog are pituitary, thyroid, parathyroid, thymus, pineal body, pancreatic islets, adrenals and gonads.

Excretory system

Frog excretes urea as nitrogenous waste. It is therefore, ureotelic animal. Urinary or excretory system consists of a pair of kidneys (mesonephric), a pair of ureters, a urinary bladder, cloaca and cloacal aperture.

- (1) **Kidneys**: The main organ of excretion are paired kidneys which are compact, dark red and bean like structures situated little posteriorly in the body cavity on both sides of vertebral column. Each kidney is composed of several structural and functional units called uriniferous tubules or nephrons. Each nephron has a Malpighian capsule, a neck and a coiled tubule which opens into a transverse collecting tube.
- (2) Ureters: They are fine transparent tubes which arise singly from back of kidney, proceed posteriorly and pass into cloaca. In male each ureter contains a swelling called seminal vesicle for temporary storage of sperms. Ureters of male are also called urinogenital ducts.
- (3) Urinary Bladder: It is distensible transparent bilobed sac which is connected to cloacal chamber below the opening of ureters. Urine coming into cloacal chamber from ureters is passed into urinary bladder for storage. As the urinary bladder gets filled, the sphincter guarding opening of urinary bladder relaxes and urine flows into cloacal chamber and from here to the outside through cloacal aperture.

Other Excretory Organs: Liver is the organ where urea is formed from ammonia released during deamination of excess amino acids. It also synthesises bile pigments (biliverdin, bilirubin) from decomposition products of haemoglobin. Bile is passed into duodenum for elimination of waste bile pigments. In rectum a small quantity of salt is excreted by its wall into faecal matter, e.g., calcium phosphate.

Reproductive System

Sexes are separate. Male frog is generally larger with narrower body. It has vocal sacs in the throat region for louder croaking. In breeding season male frog becomes brightly coloured. Its inner fingers develop nuptial or amplexusory pads. Female frog is generally smaller with broader body. During breeding season its abdomen swells up. Nuptial pads and vocal sacs are absent.

Male reproductive system: Male reproductive organs consists of a pair of elongated or ovoid yellowish testes, vasa efferentia, kidneys, urinogenital ducts and cloaca.

- (1) **Testes :** Testes are found attached to the anterio-ventral surface of kidneys by a double fold of peritoneum called mesorchium. Testis is composed of a large number of small tubes, the seminiferous tubules. The wall of seminiferous tubules is made up of germinal epithelium, which forms sperms by spermatogenesis.
- (2) Vasa efferentia: These are 10-12 in numbers and after arising from testes run through the mesorchium and enter the kidneys of their side. In kidneys, vasa efferentia open into Bidder's canal which is connected to the urinogenital duct through collecting tubules.
- (3) Urinogenital duct: The urinogenital duct comes out of the kidneys and finally opens into the cloaca. Before opening into cloaca, it dilates to form a seminal vesicle to store the sperms temporarily. In some frogs the seminal vesicles are not found.
- (4) **Cloaca**: The cloaca is a small median chamber that is used to pass faecal matter, urine and sperms to the exterior.

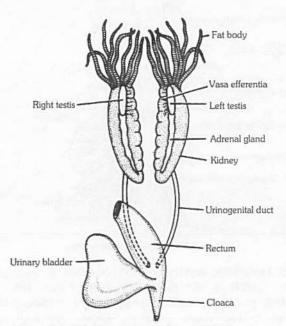

Fig: 2.4-6 Male urinogenital organs of frog

Female reproductive system : Female reproductive system of frog is formed of a pair of ovaries, a pair of oviducts and cloaca.

- (1) **Ovaries**: A pair of ovaries, situated near kidneys, comprises the female reproductive organs. The ovaries are attached to the dorsal abdominal wall, supported by a peritoneal fold called mesovarium. The wall of ovary consists of an outermost germinal epithelium. The cells of the germinal epithelium give rise to the ovarian follicle. In each follicle, one cell becomes larger than the others cells to form ovum or female gamete by oogenesis. During the breeding season, the wall of the ovary ruptures to release the ova into the coelom. A mature female can lay 2500 to 3000 ova at a time.
- (2) Oviducts: These are paired, white glandular, long, coiled tubes lying one on either side of the body cavity. Each oviduct consists of ovarian funnel, ovarian tubule and ovisac.

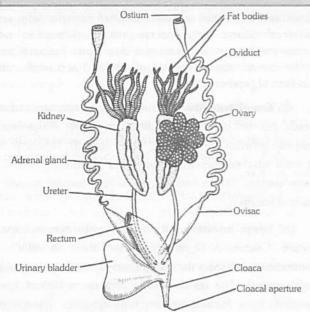

Fig: 2.4-7 Female urinogenital organs of frog

Interaction with Mankind

- (1) Frog is a beneficial animal for human being. It is used for laboratory study and is used as an experimental material for teaching and research.
- (2) Frog is a good friend of farmers as it eats on insect pests and this saves expenditure on pesticides.
 - (3i) The muscular hind legs of frog are used as food by men.
 - (4) Small froglets are used as fish bait.
- (5) Frogs maintain ecological balance because these serve as an important food link in ecosystem.

Rattus rattus (The common house Rat)

Systematic position

Phylum Chordata

 Vertebrata or Craniata Subphylum

Gnathostomata Super Class

Mammalia

Class

Order Rodentia

Family Muridae

Genus Rattus

Species - rattus (Black Rat)

Habits and Habitat

They are the common house rats which are cosmopolitan in distribution and found all over the world. They are herbivorous, fossorial and nocturnal animals and undergo hibernation. They show sexual dimorphism. They are prolific breeders. Fertilization is internal. The time interval between fertilization and birth (gestation) is about 22 to 23 days. They are completely grown at six to eight months of age. The rat breeds more than four times in a year producing 6-8 young ones in each litter. Newly born young ones are blind, deaf and without hairs. The mother feeds the young ones on milk. Average age of a rat is 3 years. The most common species are Rattus rattus (black rat) and Rattus norvegicus (brown rat or Norway rat)

External morphology

Their body is covered with hairs. The body is divisible into head, neck, trunk and tail.

Head: Head is broader posteriorly and tapers anteriorly as a naked terminal muzzle or snout. A pair of nostrils, shaped like inverted commas, is present above the mouth opening, which leads into nasal passages. Below the nostrils is the cleft upper lip, which exposes the two upper incisors. On the lateral sides of the head are large, paired bulging eyes. Eyelids have very fine and short eyelashes; the nictitating membrane is reduced. The head bears a pair of external ear or pinna at its posteriolateral position. The mouth is sub-terminal and located beneath the nostrils and remains guarded by upper and lower lips. Long, stiff, bristle-like hair known as pili lactiles or vibrissae are present on both sides of nostrils. They help the animal in measuring width of area through which the animal is to pass even in perfect darkness.

Neck: It is a short connection between head and trunk. With the help of neck the animal can bend its head in different directions.

Trunk: It is depressed fusiform major part of the body which has two parts-anterior narrow but stouter thorax and posterior wider softer abdomen. The ventral surface of female bears 6 pairs of teats or nipples, three pectoral (thoracic) and three inguinal (abdominal). The trunk bears two pairs of limbs, two forelimbs and two hindlimbs. Forelimbs are smaller than the hindlimbs. Each limb is made up of proximal segment (stylopodium), middle segment (Zeugopodium) and distal segment (autopodium). Five digits are present in autopodium of each limb. The first digit is thumb or pollex, which is much reduced with a peculiarly flattened nail and two phalanges. Nail is keratinized structure occupying position above the distal phalanx of each digit. Typical walking pads, the tori are present on the tips of digits, palm and at the base of palm. These are also present on the feet, but palms and soles do not have hair. Anus lies posteriorly at the base of tail.

Tail: It is quite long cylindrical and tapering structure that develops above the anus. It bears overlapping scales and sparse hair in between. Tail is used as a balancing organ.

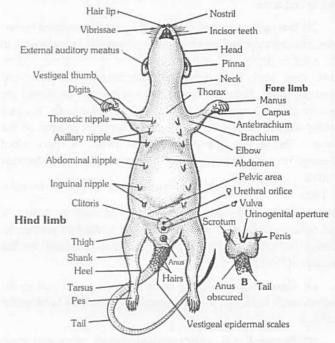

Fig: 2.4-8 External morphology of rat (a) Ventral view of female rat; (b) Ventral view of pelvic region of male rat

Internal morphology

Skin (Integument)

Histologically, the skin consists of outer epidermis and inner dermis.

- (1) **Epidermis :** Epidermis is ectodermal in origin and is made up of stratified squamous epithelium. It consists of stratum germinativum (S. malpighi), S. spinosum, S. granulosum, S. lucidum and S. corneum. There are some layers of cells above the stratum lucidum which constitute the stratum corneum. The cells contain a protein called keratin and have lost all other internal structures including nuclei.
- (2) Dermis: It develops from the mesoderm of embryo. It is composed of dense fibrous connective tissue with blood vessels, lymph vessels, nerve fibres, pigment cells etc.

Derivatives of skin: Hairs, cutaneous glands and claws are formed from the skin. Major skin glands are sudoriferous glands (sweat glands), sebaceous glands (oil glands), mammary glands (modified sweat glands), meibomian glands (modified oil glands, present along the edges of the eye lids) and ceruminous glands (wax glands, present in the external auditory canal of external ear).

Digestive system

It consists of alimentary canal and digestive glands.

Alimentary canal: Alimentary canal is coiled tube of variable diameter. It begins at mouth and ends at anus. The various parts are mouth, buccopharyngeal cavity, oesophagus, stomach, small intestine (duodenum, jejunum and ileum), large intestine (caecum, colon and rectum) and anus.

- (1) Mouth: The mouth opens in the buccal cavity that is surrounded by the vestibule, which is a space between the lips, cheeks and teeth.
- (2) Buccopharyngeal cavity: It is a space enclosed by two jaws. Buccopharyngeal cavity consists of broader buccal cavity in the anterior region and narrow pharynx in the posterior region. Jaws bear teeth. The teeth are heterodont, the codont and monophyodont. Each jaw carries two incisors and six molars the incisors grow throughout life and act as growing teeth. A sharp cutting edge is maintained due to the absence of enamel on the surface. The canines and premolars are absent. A space called diastema occurs between incisors and molars. The dental formula
- is $\frac{1003}{1003} \times 2 = 16$. The middle of buccal cavity contains a muscular

tongue. Taste buds occurs on tongue as well as lining of buccopharyngeal cavity. Unlike frog tongue is attached posteriorly. Behind lies pharynx. Pharynx is a common chamber for the passage of food and air.

- (3) Oesophagus: It is a short tube situated dorsal to the trachea and it leads into the pear-shaped or somewhat semicircular stomach.
- (4) Stomach: It is wide curved part of alimentary canal which lies on the left side behind the diaphragm. It has a greater

curvature on left side, a lesser curvature on right side, cardiac orifice/valve where oesophagus open into it and pyloric sphincter is narrow posterior and where it meets duodenum. Stomach contains goblet cells for mucus, oxyntic cells for HCl and peptic cells for secretion of pepsinogen.

- (5) Small intestine: Stomach leads into small intestine, which can be differentiated into three parts duodenum (U-shaped), jejunum (straight) and ileum (coiled). Digestive glands of small intestine secrete intestinal juice or succus entericus. The same contain lipase, nuclease, peptidase, lactase, sucrase and maltase enzymes.
- (6) Large intestine: It has three part-caecum, colon and rectum. Caecum is slightly constricted about its middle. The constriction sub divides the caecum into two parts, an apical and a basal portion. The apical portion contains a distinct mass of lymphoid tissue forming the vermiform appendix. Caecum opens into the first part of large intestine, the colon which is divisible into an ascending, a transverse and a descending colon leads into rectum, which opens outside through the anus.

Digestive glands

- (1) Salivary glands: There are three pairs of salivary glands.
- (i) Sublingual glands
- (ii) Submandibular glands and
- (iii) Parotid glands.

Infraorbital salivary glands are reported but probably they are absent in rat, however, dogs have these glands.

- (2) Liver: It is the largest gland of the body which is located in the upper and right side of the abdominal cavity below the diaphragm. The liver of rat consists of four lobes (left, middle, right and caudate) and the spigelian lobe is a part of caudate lobe. The cells of liver are called hepatocytes which secrete bile. Bile is carried to the duodenum by bile duct. Bile contains no digestive enzymes but helps in digestion of food in the small intestine. Gall bladder is absent in rat. Gall bladder is also absent in whale and horse.
- (3) Pancreas: It is a very diffuse structure and is present between the duodenal loops. It secretes pancreatic juice which contain digestive enzymes such as trypsinogen (proenzyme), amylopsin and lipase. Islets of Langerhans of the pancreas secrete certain hormones such as insulin. Insulin converts glucose into glycogen in the liver and muscles.
- (4) Gastric Glands: These are found in stomach and secrete gastric juice containing digestive enzymes (e.g., pepsin) and hydrochloric acid (HCl) which help in digestion of food.

UNIVERSAL BOOK DEPOT 1960

(5) Intestinal Glands: These are present in the small intestine and secrete intestinal juice containing digestive enzymes (e.g., maltase, sucrase, lipase, etc.) which help in digestion of food.

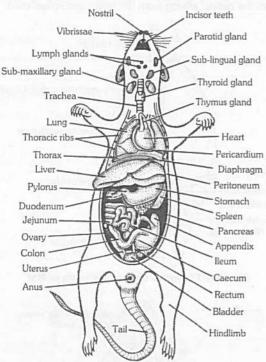

Fig: 2.4-9 General anatomy and digestive system of rat

Respiratory system

It consists of respiratory tract, two lungs and a mechanism for inspiration and expiration. Respiratory tract consists of nostrils, nasal chambers, internal nares, glottis, larynx, trachea, bronchi, and bronchioles. The nostrils lead into the olfactory or nasal chambers. The two nasal chambers lead into pharynx through internal nares. Pharynx contains a slit like glottis, which leads into voice box called larynx. Larynx passes into trachea and wind pipe which runs ventral to oesophagus. Trachea divides into two primary bronchi that pass into lungs. The lungs are placed one on either side of the heart lying in the thoracic cavity and are covered by visceral pleura. There are three lobes of the right lung and only one in the left. Each lung possesses a large number of alveoli where gaseous exchange occurs between air and blood.

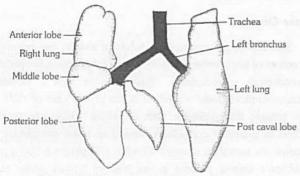

Fig: 2.4-10 Trachea and Lungs of Rat

Circulatory system

The circulatory system of rat consists of blood vascular system and lymphatic system.

 Blood vascular system: Like other mammals rat possesses closed and double circulation. Blood vascular system comprises blood, heart and blood vessels.

Blood: The volume of blood is about 5-7 ml/100 gm body weight. The blood consists of blood plasma and three types of blood corpuscles namely RBCs (6-7 lac/cubic microlitre), WBCs (6-10 thousands/cubic microlitre) and platelets. RBCs are without nucleus on maturation. They contain haemoglobin (respiratory pigment). WBCs provide immunity and defence against diseases. The platelets help in clotting of blood.

Heart: The heart lies on the midline and placed obliquely in the thoracic cavity, surrounded by pericardial cavity. The heart has four chambers; the right atrium and right ventricle and the left atrium and left ventricle. Blood flows from the right atrium into the right ventricle via the tricuspid valve (right atrio-ventricular valve) with three cusps of fibrous tissue. Blood flows from the left atrium into the left ventricle via the bicuspid or mitral valve (left atrioventricular valve). Aortic and pulmonary valves each have three leaflets and called semilunar valve. The right cardiac arteries supply right and left atria, whereas the left cardiac arteries only supply to small portion of the left atrium. Well developed arterial and venous system similar to other mammals is found in the rat. Only the left aortic arch is present and two precavae are present in the rat. Hepatic portal system is present which comprises veins collecting blood from alimentary canal and supply to the liver after branching in capillaries. The renal portal system is absent.

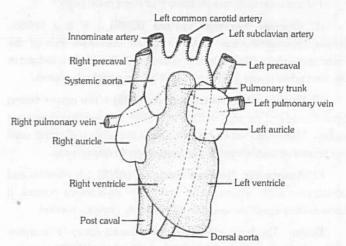

Fig: 2.4-11 Heart of rat in ventral view

(2) Lymphatic system: It consists of lymph, lymph vessels and lymph nodes. Lymph is colourless fluid which is similar to blood but lacks red blood corpuscles and blood platelets. Lymph is formed by lymph capillaries from tissue fluid. Lymph capillaries join to form lymph vessels. At places lymph vessels bear lymph nodes. The latter contain minute channels where germs are entrapped by leucocytes. Lymph nodes also produce lymphocytes. Tonsils a type of lymphatic node are, however, absent. Lymph vessels form lymph ducts of two types, right and thoracic. They also open into veins.

Excretory system

The excretory system includes paired kidney, ureters, a urinary bladder and urethra.

- (1) **Kidneys**: There is a pair of kidneys which are dark red and bean shaped. The right kidney is slightly higher in position. The kidney consists of outer cortex and inner medulla. A kidney has numerous structural and functional units called nephrons (= uriniferous tubules). Each nephron is made up of Bowman's capsule, proximal convoluted tubule (PCT), Henle's loop and distal convoluted tubule (DCT). The Bowman's capsule is a cup shaped structure which contains a meshwork of blood capillaries, the glomerulus. Filtration of metabolic wastes takes place in the glomerulus and then to the other parts of the nephron.
- (2) Ureters: There is a pair of ureters. Each ureter arises from each kidney. Ureters carry urine from the kidneys to the urinary bladder.
- (3) **Urinary bladder**: It is muscular sac-like structure in which two ureters open. The urinary bladder stores urine temporarily.
- (4) Urethra: In male it carries both urine and semen. In female it carries urine only. Thus in male rat there is only one urinogenital aperture to pass urine and semen. However in female rat both urinary and genital apertures are separate.

Nervous system

The nervous system is divisible into three main parts:

- (1) Central Nervous System (CNS): It is a hollow, dorsally placed structure lying along the middorsal axis of the body. It comprises the brain and spinal cord. The brain is lodged in the skull while spinal cord is enclosed by the vertebral column.
- (2) Peripheral Nervous system (PNS): The nerves arising from the central nervous system constitute the peripheral nervous system. The nerves which originate from the brain and spinal cord are known as cranial nerves and spinal nerves respectively.
- (3) Autonomic Nervous System (ANS): It controls and coordinates such organs which are under involuntary control. It consists of sympathetic and parasympathetic nervous system.

Brain : The brain is lodged in the cranial cavity (= cranium of the skull). It is covered by three membranes called meninges. The inner most membrane is called piamater, the next is the arachnoid mater (= arachnoid membrane) and outer most is the duramater. The sub dural space is present below the dura mater and sub arachnoid space lies below the arachnoid mater. These spaces are filled with a fluid. The meninges are protective in function.

The brain is composed of two large hemispheres separated by a median fissure. The cerebral hemispheres form the largest part of the brains. The posterior portion of the brain is composed of medulla oblongata which tapers in the spinal cord. The spinal cord

is a long tube like thick walled structures which emerges out through the foramen magnum of the skull and passes through neural canal of vertebral column. The peripheral nervous system comprises the nerves arising from the brain and spinal cord.

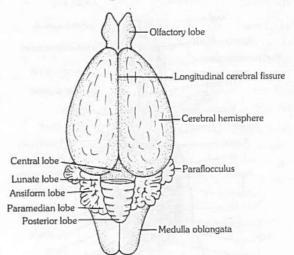

Fig: 2.4-12 Dorsal view of the brain of Rat

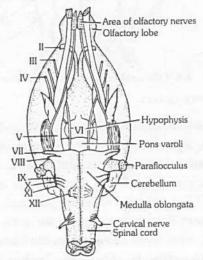

Fig: 2.4-13 Ventral view of the brain of Rat

Cranial nerves : Rat has 12 pairs of cranial nerves originating from brain.

Spinal Nerves: 33 pairs which come out from intervertebral foramina. Spinal nerves are mixed. They supply various organs in the area of their origin.

Sense Organs

Skin has tangoreceptors (receptors of touch), thermoreceptors (receptors of temperature) algesioreceptor (receptors for pain) and rheoreceptors (receptors for current or vibrations). Gustatoreceptors (taste receptors) occur in the form of taste buds over tongue and posterior part of palate. Olfactoreceptors are located in olfactory epithelium present in nasal chambers. They perceive the sensation of smell. Smell is also perceived by a pair of Jacobson's organs present in the wall of buccal cavity of Rat. Organs of sight are eye while statoacoustic organs are ears.

Reproductive system

Male Reproductive system: The male reproductive organs of a rat are a pair of testes, epididymis, vas deferens, urethra, penis and spermatic cord.

- (1) **Testes**: A pair of testes is found in the scrotal sacs. Each testis is an elongated and ovoid body attached posteriorly to scrotal sac by gubernaculum. Testis of male rat descends in the scrotal sacs between the 30th to 40th day of life through inguinal canal. The inguinal canal remains open through out life, but during sexually inactive period, the testis may be withdrawn into abdominal cavity.
- (2) Epididymis: These are paired structure. Each epididymis is a mass of long narrow coiled tubule lying along the testis which consists of anterior caput epididymis, middle corpus epididymis and posterior cauda epididymis. Epididymis stores the sperms.
- (3) Vasa deferentia: There is a pair of vasa deferentia. A vas deferens arises from the cauda epididymis. Vasa deferentia carry sperms.
- (4) Seminal vesicles: There is a pair of seminal vesicles which are large and lobulated except for the smooth tip which is doubled back upon itself. They are not store houses for sperms. Their secretion is alkaline and forms the bulk of seminal fluid (semen).
 - (5) Urethra: It is divided into three parts -
 - (i) Prostatic urethra is surrounded by the prostate gland.
- (ii) Membranous urethra is the shortest portion and runs from the prostate to the bulb (base) of the penis.
- (iii) Penile urethra passes through the penis and opens at the tip of the penis as urinogenital aperture.
- (6) Penis: It is a copulatory organ which is covered by a loose sheath, the prepuce. The penis of the rat has a bony process called the os penis. Penis bone is also present in bat, dog, walrus and whale.

Accessory Glands : Male accessory sex glands -

- (1) Ampullary glands: The outer end of the vas deference near the entrance into the urethra is enlarged into ampulla, which contain ampullary glands to secrete mucus.
- (2) Vesicular glands: These are branched glands which originate from the vas deferens behind the ampulla.
- (3) Coagulating glands: Closely applied along the minor curvature of the seminal vesicles and within the same sheath are the coagulating glands. The secretion of these glands serve to coagulate the seminal fluid (Semen).
- (4) **Prostate glands**: There are two prostate glands whose secretion is rich in citric acid, lipid and acid phosphatase.
- (5) **Cowper's glands:** (Bulbo-urethral glands): These are one pair which originate from the urethra at the base of penis. They produce a secretion during sexual excitement which protects the sperms from traces of acids found in the urethra (as the urine also passes through the penile urethra).

(6) Preputial glands (Glands of Tyson): They develop from the skin forming prepuce. They are modified sebaceous (oil) glands which secrete peculiar odorous secretion.

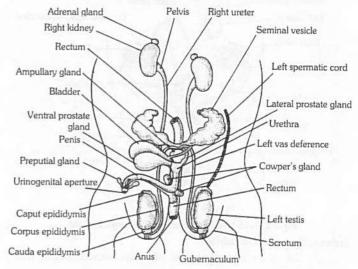

Fig: 2.4-14 Male urinogenital organs of rat

Female reproductive system: The female reproductive organs consists of a pair of ovaries, fallopian tubes two uteri, a single common vagina and a clitoris. Female rats mature rapidly and becomes sexually mature in about 72 days.

- (1) **Ovaries :** Ovaries are paired small yellowish compact structure suspended in the body cavity by mesovarium.
- (2) Fallopian Tubes (Oviducts or uterine tubes): There is one pair of convoluted Fallopian tubes. Each Fallopian tube begins with fimbriated funnel which receives ova from the ovary. As the fertilization is internal, it takes place in the dilated upper most portion of the Fallopian tubes.
- (3) Uterus (Womb): The uterus is a hollow muscular structure. The uterine horns are fused near vagina. The wall of the uterus consists of outer covering of peritoneum, the perimetrium, middle layer of smooth muscle fibres, the myometrium and inner layer of simple columnar epithelium, the endometrium. The embryo gets attached to the uterine wall through placenta. Embryonic development takes place in the uterus. Placenta provides the physiological connection between developing foetus and uterine wall (endometrium) of the mother.
- (4) **Vagina**: It is a tubular structure which extends from the uterus and opens outside as vaginal opening (= vulva). Penis of the male rat is inserted into the vagina during copulation. The vagina also helps to deliver the young ones at the time of birth.
- (5) Clitoris: It corresponds to the penis of the male but it is reduced in size and does not have any passage (it is solid structure). The clitoris is found anterior to the vulva.

Accessory Glands

- (1) **Vestibular glands**: These are small mucous glands which open on the surface of the vestibule of the vagina.
- (2) **Bulbo-urethral glands**: These are small glands which are present in relation with the urethra.

(3) Preputial glands: There is one pair of large preputial glands which are near the tip of the clitoris.

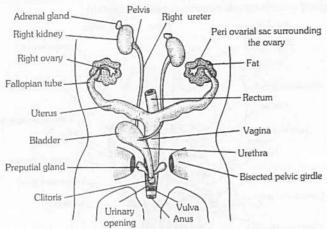

Fig: 2.4-15 Female urinogenital organ of rat Interaction with mankind

- (1) Rat is an important pest of crops, stored grains, fruits, vegetables, etc.
- (2) Rat destroys field by making burrows and tunnels which often provide shelter to snakes.
- (3) Rat makes burrows in the houses and causes damage to the household including books, clothes, food, etc.
- (4) Rat is a host of rat flea, Xenopsylla, which is the vector for the disease bubonic plague.
- (5) Rat is an important component of food chain as several animals like cats, snakes, mongoose, owls and some other birds
- (6) The albino rat that is commonly used for teaching and researches in institutions is a product of laboratory breeding.
- (7) The albino rats are also used as an experimental animal to test drugs that are to be finally used by the human beings.

Note : See Morphology, Anatomy and functions of different systems (digestive, circulatory, respiratory, nervous and reproductive) of an insect (cockroach) is given in the chapter 1.7 Animalia (Phylum Arthopoda) page no. 206.

Tips & Tricks

- Frog's skin is not concerned with thermoregulation. There is no synthesis of vitamin D in the skin of frog. Frog can absorb water through the skin.
- E Digit formula of fore limb of frog is 0, 2, 2, 3, 3. Digital formula of hind limb of frog is 2, 2, 3, 4, 3
- Largest Frog. : Rana goliath (35 cm).
- The scientific study of body movements is known as kinesiology.
- Wistar Rat is an inbred strain of rats, homozygous for most traits, produced by strict brother-sister inbreeding over many generations to develop animals for research with the same general genetic composition (wistar Institute).
- Rat population is 70 times that of humans. 6 rats consume food equivalent to one human being.

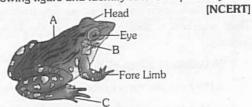

Ordinary Thinking

Objective Questions

Morphology of Frog

- Frogs and toads belong to the order
 - [Odisha JEE 1995]

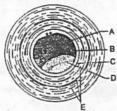

- (a) Anura
- (b) Apoda
- (c) Caudata
- (d) Gymnophiona
- The cloaca in frog is a common chamber for the urinary 2. tract, reproductive tract and [Kerala PMT 2008; AFMC 2010]
 - (a) Alimentary canal
- (b) Portal system
- (c) Hepaticportal vessels
- (d) Notochord
- (e) Lymphatic system
- Which one of the following is not a characteristic feature of 3. [Kerala PMT 2009]
 - (a) The skin is moist and slimy
 - (b) Each of the fore limbs and hind limbs end in five digits
 - (c) Hepatic portal and renal portal systems are present
 - (d) Skin, buccal cavity and lungs are the respiratory organs
 - (e) Heart is three-chambered
- See the following figure and identify A to C respectively

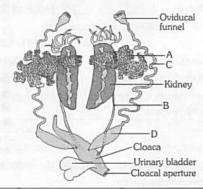

- (a) Neck, Tympanum, Hind limb
- (b) Trunk, Tympanum, Hind limb
- (c) Neck, Brown eye spot, Web
- (d) Trunk, Tympanum, Web
- The scientific name of common toad is
 - (a) Hyla arborea
- (c) Bufo melanostictus
- (b) Xenopus laevis
- (d) Bombinator igneus
- The toad possesses
- [BVP 2001]
- (a) Bifid tongue, slippery skin and mucous glands
- (b) Salivary glands, mucous glands and parotid glands
- (c) Parotid glands, warty skin and semicircular snout
- (d) Slippery skin, yellow pigment and abundant mucous glands
- Parotid glands are found in 7.
 - (a) Bufo
- (b) Hyla
- (c) Rana
- (d) Alytes
- Which statement is true about the venous blood vessels of 8. [AMU (Med.) 2010]
 - (a) Lingual and submandibular unite to form the internal jugular
 - Musculo-cutaneous and brachial unite to form the subclavian
 - (c) The ventral abdominal vein drains into the posterior vena cava
 - (d) The pelvic veins unite to form the renal portal vein
- Frog hibernate during
 - (a) Winter
- (b) Spring
- (c) Summer
- (d) autumn
- The summer sleep of frog is termed as 10.
 - (b) Aestivation
 - (a) Neoteny
- (c) Paedogenesis
- (d) Hibernation

11. The following is a diagram of the just spawned frog's egg; with the parts labelled from A to E. Identify the parts and choose the correct option from those given below

[KCET 2006]

- (a) A= cytoplasm, B= plasma membrane, C= vitelline membrane, D= yolk, E= jelly coat
- (b) A= cytoplasm, B= vitelline membrane, C= plasma membrane, D= yolk, E= jelly coat
- (c) A= volk, B= plasma membrane, C= vitelline membrane, D= cytoplasm, E= jelly coat
- (d) A= yolk, B=jelly coat, C= vitelline membrane, D= cytoplasm, E= plasma membrane
- 12. Dissection of frog is done from ventral side because
 - (a) Ventral skin is soft
 - (b) Abdominal vein is present ventrally
 - (c) Vertebral column is present on dorsal side
- The given figure is related with female reproductive system 13. of frog. Identify A to D [NCERT]

	A	В	C	D
(a) Ovary		Urinogenital duct	Bidder's canal	Oviduct
(b)	Ovary	Urinogenital duct	Ovisac	Oviduct
(c)	Ovary	Urinogenital duct	Bidder's canal	Ovisac
(d)	Ovary	Ureter	Oviduct	Ovisac

- 14. Male frogs can croak louder than females because of
 - (a) Vocal sacs
- (b) Stronger
- (c) Larger in size
- (d) Larger sound box
- 15. Croaking of frog is

[AIIMS 1996; EAMCET 1999; CPMT 2000]

- (a) Hunger call
- (b) Danger call
- (c) Musical tone
- (d) Sex call for female
- 16. The development of frog is
 - (a) Direct
- (b) Indirect
- (c) Parthenogenetic
- (d) None of these
- 17. How many eggs are laid by a female frog at a time
 - (a) 100 200
- (b) 500 1000
- (c) 2500 3000
- (d) 5000 6000

- The opening of rectum in frog is called **ICBSE PMT 20001**
 - (a) Vestibule
- (b) Cloaca
- (c) Coccyx
- (d) None of the above
- A common cloacal aperture is found in
 - (a) Rana
- (b) Nereis
- (c) Rabbit
- (d) Pheretima
- Observe the following figure indicating the male 20. reproductive system of frog. Identify A, B, C and D [NCERT]

	A	В	C	D
(a)	Vasa efferentia	Thyroid gland	Urinogenital duct	Cloaca
(b)	Vasa efferentia	Adrenal gland	Urinogenital duct	Cloaca
(c)	Bidder's canal	Adrenal gland	Urinogenital duct	Cloaca
(d)	Bidder's canal	Adrenal gland	Urinogenital duct	Rectum

- Disappearance of the tadpole tail during metamorphosis is brought about by [AMU (Med.) 2010]
 - (a) Endoplasmic reticulum
- (b) Golgi bodies
- (c) Lysosomes
- (d) Peroxisomes
- The number of fingers in the hindlimb of frog is [NCERT]
 - (a) 4

(b) 5

(c) 6

- (d) 7
- 23. In the buccal cavity of frog the internal nares are
 - (a) One
- (b) Two
- (c) Fused
- (d) Absent

- 24. Mucus helps frog in making
- [CBSE PMT 1993]
- (a) Dry skin
- (b) Moist skin
- (c) Rough skin
- (d) Thick skin
- 25. Acrosome of the sperm of frog helps in fertilization by
 - (a) Activating the oocyte to engulf the sperm
 - (b) Inducing formation of cone of reception in oocyte
 - (c) Stimulating oocyte to undergo second maturation division
 - (d) Secreting sperm lysin to dissolve covering membrane of
- 26. Chromatophores in skin of frog found in stratum

[CBSE PMT 1992, 93]

- (b) Compactum
- (c) Germinativum
- (d) Mostly spongiosum
- One of the main functions of frog's skin is

[NCERT; CBSE PMT 1991]

- (a) Diffusion of respiratory gases
- (b) Absorption of ultraviolet rays to produce vitamin D
- (c) Storage of excess food in the form of subcutaneous fat
- (d) Excretion of nitrogenous waste in the form of uric acid

- When a sperm enters an egg of frog 28.
 - (a) First polar body is formed
 - (b) First meiotic division occurs
 - (c) Second meiotic division occurs
 - (d) Fertilization process is compeleted
- In frog, jelly around the eggs is deposited in [BHU 2000] 29.
 - (a) Ovary
- (b) Oviduct
- (c) Water after fertilization (d) Water during fertilization
- Consider the following four statements (A D) related to the common frog Rana tigrina and select the correct option stating which ones are true (T) and which ones are false (F)

- (A) On dry land it would die due to lack of O₂ if its mouth is forcibly kept closed for a few days
- (B) It has four-chambered heart
- (C) On dry land it turns uricotelic from ureotelic
- (D) Its life-history is carried out in pond water

Opt	ions		1	NCERT; CE	BSE PMT (Mains) 2011]
	(A)	(B)	(C)	(D)	
(a)	F	F	T	T	
(b)	F	T	T	F	
(c)	T	F	F	T	
(d)	T	T	F	F	

- 31. A Bidder's canal in each kidney of frog
 - (a) Runs longitudianally in lateral region of kidney
 - (b) Runs longitudianally in medial region of kidney
 - (c) Runs tranversely across the width of anterior part of kidnev
 - (d) Runs transversely across the width of posterior part of kidney
- 32. In frog, the surface of attachment of tongue is

[CBSE PMT 1992, 97]

- (a) Palatine
- (b) Sphenoid
- (c) Pterygoid
- (d) Hyoid apparatus
- Read the statements with regard to frog. Which of the 33. statement(s) is/are correct and incorrect
 - The medulla oblongata passes out through foramen of Monro and continues into spinal cord
 - Vasa efferentia are 10-12 in number that arise from testes
 - 3. Ovaries have no functional connection with kidneys
 - 4. Frogs are uricotelic

[Kerala PMT 2011]

- (a) 1, 2 and 3 are correct but 4 is incorrect
- (b) 1 and 2 are correct while 3 and 4 are incorrect
- (c) 2 and 3 are correct while 1 and 4 are incorrect
- (d) 2, 3 and 4 are correct while 1 is incorrect
- (e) 3 and 4 are correct while 1 and 2 are incorrect
- In frog pyloric sphincter is located between
 - (a) Fundus and pylorus (b) Cardiac and fundus
 - (c) Oesophagus and pharynx(d) Stomach and duodenum
- In frog, digestion of fats occurs mostly in 35.

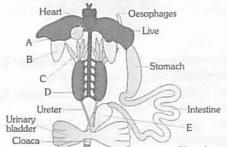

[NCERT: CBSE PMT 1993]

- (a) Rectum
- (b) Stomach
- (c) Duodenum
- (d) Small intestine

A fully grown tadpole larva of frog respires through

IBCECE 20011

- (a) Gills
- (b) Skin
- (c) Lungs
- (d) Tail fin
- The given figure is related to diagrammatic representation of internal organs of frog. Identify A to E

Cloacal aperture

	A	В	C	D	E
(a)	Gall bladder	Lung	Fat bodies	Kidney	Rectum
(b)	Gall bladder	Lung	Testis	Kidney	Rectum
(c)	Gall bladder	Lung	Fat bodies	Testis	Rectum
(d)	Gall bladder	Lung	Ovary	Testis	Rectum

- If the mouth of frog is kept open for some time, it dies because it is unable to
 - (a) Eat
- (b) Drink
- (c) Breath
- (d) None of these
- During hibernation, frog respires with

[Manipal 2001; CBSE PMT 2001]

- (a) Lung only
- (b) Moist skin only
- (c) Buccal cavity only
- (d) External gills and lungs
- 40. Oxygen carrier or the respiratory pigment in blood of frog [CPMT 1992] and other vertebrates is
 - (a) Myoglobin
- (b) Cytochorome
- (c) Haemoglobin
- (d) Haemocyanin
- A frog must swallow air to expand the lungs because frog
 - (a) Has no diaphragm
 - (b) Has no vagus nerve
 - (c) Is relatively primitive vertebrate
 - (d) Normally breathe though its skin
- 42. In frog, glottis is controlled by muscles of
 - (a) Sternum
- (b) Vocal cords
- (c) Pectoral girdle
- (d) Arytenoid cartilages
- 43. The lungs in frogs are
 - (a) Compact spongy masses
 - (b) Thin-walled elastic, hollow bags
 - (c) Thick-walled nonelastic, hollow bags
 - (d) Thick-walled nonelastic solid masses
 - In frog, respiration occurs by

[NCERT]

- (a) Lungs
- (b) Trachea
- (c) Gills only
- (d) Both (a) and (b)
- In which of these animals, skin serves as an accessory organ 45. [CBSE PMT 1990; WB JEE 2010] of respiration
 - (a) Bird
- (b) Frog
- (c) Lizard
- (d) Rabbit

UNIVERSAL BOOK DEPOT 1960

46.	In frog, cutaneous respiration takes place [NCERT; CBSE PMT 1992]	56.		heart of frog beats 25 times/min.		te of o) 64 times/min.
	(a) Always		200	72 times/min.		d) 100 times/min.
	(b) Only on land	57 .	2000			iffers from that of rabbit
	(c) Only in water with pulmonary respiration		hav			mere nom mar or radon
	(d) Only in water pulmonary respiration is not occurring			Hepatic vein	(1) Three vena cavae
47.	The epithelial lining of respiratory system in frog is derived			Renal portal syster	n (c	d) Hepatic portal system
	by [CPMT 1993]	58.		Control of the Contro		od from tongue is termed
	(a) Ectoderm			Lingual) Azygous
	(b) Endoderm		(c)	Cutaneous	(0	d) Anterior abdominal
	(c) Mesoderm	59.	Scia	atic vein of frog ope	ns in	[BHU 2005
	(d) Mesoderm and endoderm		(a)	Heart	(t) Kidney
48.	Frogs differ from humans in possessing [NCERT;		(c)	Pelvic region	(c	d) Liver

49.	Heart of frog differs from that of man by presence of	61.	Mat	ch the following co	olumn I	with coloumn II and choos
	[NCERT]		the	correct combination	1.	
	Or			Column I		Column II
	Heart of rat differs from that of frog by the absence of		(a)	Earthworm	(i)	Gizzard
	(a) Two aortae (b) Mitral valve		(b)	Cockroach	(ii)	Caecum
	(c) Sinus venosus (d) Four-chambers		(c)	Frog	(iii)	Clitellum
50.	The sinus venosus is located on		(d)	Rat	(iv)	Cloaca
	(a) Dorsal surface of the heart of frog					[Kerala CET 2005
	(b) Ventral surface of the heart of frog			(a) - (i), (b) - (ii), (a)		
	(c) Dorsal surface of the heart of rabbit			(a) - (iii), (b) - (i),		
	(d) Ventral surface of the heart of rabbit			(a) - (iii), (b) - (i),		
51.	In frog [CBSE PMT 1991]			(a) - (i), (b) - (iii),		, (d) – (ii)
	(a) Acetylcholine is the only neurotransmitter	62.	Fen	estra ovalis in frog i		
	(b) Noradrenaline is the only neurotransmitter					KCET 2001; MHCET 2002
	(c) Both acetylcholine and noradrenaline act as			Air-filled cavity of		
	neurotransmitters				and the second second	harynx and tympanic cavity
	(d) Neither acetylcholine nor noradrenaline acts as neurontransmitter		(c)	tympanic membras		npanic cavity covered b
52.	Amphibian heart is [NCERT; AFMC 2001]		(d)	HEART TO THE WORLD STORE TO SERVE THE STORE OF THE SERVE THE SERV		ule which separates middl
JZ.				ear from internal e		
	(a) One-chambered (b) Three-chambered	63.		n excretory organs		
	(c) Two-chambered (d) Four-chambered		Al Assault	Skin) Lungs
53.	Ureters act as urinogenital ducts in	64		Kidneys	(0	l) Malpighian tubules
	[NCERT; CBSE PMT 1991, 92; CBSE PMT (Mains) 2011]	64.		og, sclerotic is Bony	/1-) Fibrous
	(a) Frog's both males and females			Cartilaginous		None of these
	(b) Frog's males	65.		A 2011	100	ral side of the kidney in fro
	(c) Human males			called		iai side of me maney in no
	(d) Human females		(a)	Ostia	(b) Nephrostomes
54.	Mesorchium in frog refers to [NCERT; CBSE PMT 1990]		(c)	Corpora adiposa	(d	l) Bidder's organ
	(a) Fold of peritoneum between a kidney and a testis	66.		v do you differentia		
	(b) Internal tissue of testes			Frog has no exoske		
	(c) Capsules of testes		(b)		ugh lung	s but toad respires through
	(d) None of these			skin		
55.	When heart of frog is cut, it will			Frog has a tail but		
	(a) Not beat at all		(D)	parotid glands	otia gian	ds but toad has a pair of
	(b) Stop beating soon after	67.	In f-	parolid glands og the urinary blad	dor is	INCEPT
	(c) Continue to beat for a long time it kept dry	07.				[NCERT
	(d) Continue to beat for a long time it kept dry		80.30	Absent) Paired
	(a) Committee to cour for a long time it helpt moist		(C)	Bilobed	(0	None of these

58.	When an electric shock is given to the leg of a pithed frog it	Participal Control	Morphology of Rat
	(a) Blinks its eyes (b) Shows no response	1.	The most important mammalian character of rat is
	(c) Put out its tongue (d) None of these		(a) Hair (b) Pinna
59.	Which of these is an ear ossicle in frog [CBSE PMT 1990]		(c) Diaphragm (d) Mammary glands
	(a) Incus (b) Auricle	2.	The second layer of epidermis in rat integument is
	(c) Malleus (d) Columella auris		[Kerala PMT 2009]
70.	Nitrogenous excretory product of tadpole of frog is		(a) Stratum lucidum (b) Stratum germinativum
	[CBSE PMT 1992, 93]		(c) Stratum corneum (d) stratum granulosum
	(a) Urea (b) Guanine	_	(e) Dermis
	(c) Uric acid (d) Ammonia	3.	In rat, testes lie in
71.	A frog has		(a) Scrotum (b) Thoracic cavity (c) Abdominal cavity (d) Retroperitoneal position
	(a) Eyes but no lids (b) Jaws but no teeth	4	(c) Abdominal cavity (d) Retroperitoneal position Rats are
	(c) Hands but not fingers (d) Ears but not pinnae	4.	(a) Arboreal (b) Fossorial
72.	Which of the following is absent in frog		(c) Scansorial (d) None of these
	(a) External ear (b) Middle ear	5.	The common brown rat is
	(c) Internal ear (d) None of these	٥.	(a) Rattus rattus (b) Rattus meltada
73.	Which part of the brain of frog is called pallium		(c) Rattus norvegicus (d) Bandicota bengalensis
	(a) Roof of paracoel (b) Floor of epicoel	6.	The three parts of the limb of a rat from proximal to distal
	(c) Roof of rhinocoel (d) Roof of metacoel		end are
74.	Number of spinal nerves in frog is [CPMT 2010]		(a) Autopodium, zeugopodium and stylopodium
	(a) Ten only (b) Ten pairs		(b) Stylopodium, zeugopodium and autopodium
	(c) Twelve pairs (d) Twenty pairs		(c) Stylopodium, autopodium and zeugopodium
75.	What will happen if the eyes of a frog are covered by paper		(d) Zeugopodium, autopodium and stylopodium
	[CBSE PMT 1990]	7.	Accessory glands associated with the genital organs in
	(a) Frog will soon die		female rats are
	(b) Frog will not move		(i) Vestibular Bartholins (ii) Cowper's glands (iii) Ampullary glands (iv) Vesicular gland
	(c) Frog will not do any thing		(iii) Ampullary glands (iv) Vesicular gland [Kerala PMT 2009]
	(d) Frog will move to one side only		(a) (i) and (ii) (b) (iii) and (ii)
76.	The second cranial nerve of frog is		(c) (iv) only (d) (iii) only
	(a) Optic (b) Vagus		(e) (i) only
	(c) Auditory (d) Trochlear	8.	The chromosome number in Rattus rattus is
77.	Eighth cranial nerves of frog connects the brain to		(a) 40 (b) 42
	(a) Nose (b) Ears		(c) 44 (d) 38
	(c) Tongue (d) Pharynx	9.	How many nipples are present in a female rat
78.	Select the correct route for the passage of sperms in male		(a) Two pairs (b) One pairs
	frogs [NEET 2017]		(c) Three pairs (d) Six pairs
	(a) Testes \rightarrow Bidder's canal \rightarrow Kidney \rightarrow Vasa efferentia \rightarrow	10.	The teeth of rat are
	Urinogenital duct → Cloaca		(a) Homodont, acrodont and diphyodont
	(b) Testes → Vasa efferentia → Kidney → Seminal vesicle		(b) Heterodont, thecodont and diphyodont
	\rightarrow Urinogenital duct \rightarrow Cloaca		
	(c) Testes \rightarrow Vasa efferentia \rightarrow Bidder's canal \rightarrow Ureter \rightarrow		(d) Heterodont, pleurodont and polyphyodont
	Cloaca	11.	Which of the following teeth are absent in a rat (a) Canines and molars (b) Incisors and molars
	(d) Testes → Vasa efferentia → Kidney → Bidder's canal →		(c) Incisors and premolars (d) Canines and premolars
	Urinogenital duct → Cloaca	12.	The total number of teeth in a rat
79.	Frog's heart when taken out of the body continues to beat		(a) 10 (b) 16
	for sometime		(c) 20 (d) 28
	Select the best option from the following statements	13.	Which type of placenta is found in a rat
	(A) Frog is a poikilotherm		(a) Epitheliochorial (b) Haemochorial
	(B) Frog does not have any coronary circulation		(c) Haemoendothelial (d) Endotheliochorial
	(C) Heart is "Myogenic" in nature	14.	
	(D) Heart is autoexcitable		(a) Rat (b) Man (c) Both (d) None
	Options [NEET 2017]	15.	(c) Both (d) None Premolars are absent in
	(a) Only (C) (b) Only (D)	10.	(a) Rat (b) Elephant
	(c) (A) and (B) (d) (C) and (D)		(c) Both of these (d) None of these

- The life span of rat is about 16. (a) Two years (b) Four years (c) Six years (d) Eight years 17. Which of the following is present in a rat not in a frog (a) Ileum (b) Jejunum (c) Stomach (d) Duodenum 18. Select the false statement [Kerala PMT 2006] (a) In rats the teeth are heterodont and thecodont (b) In female rats, the urinary and genital apertures are located above anus (c) In female rats, six pairs of nipples are present on the ventral surface of the trunk (d) In rats, 12 pairs of cranial nerves and 33 pairs of spinal nerves are present (e) In rats, the gestation period is 22 - 23 days 19. Which type of circulation is found in rat (a) Open and double (b) Open and single (c) Closed and single (d) Closed and double 20. Gestation period of rat is (a) 20-22 days (b) 28-32 days (c) 52-65 days (d) 60-65 days The site of fertilization in rat is 21. (a) Vagina (b) Uterus (c) Vestibule (d) Fallopian tube 22. How may meninges are present in rat (a) Two (b) Three (c) Four (d) Many Which aortic arch is present in a rat 23. (a) Left (b) Right (c) Both (d) None 24. Hepatic portal system collect blood from (a) Liver (b) Lungs (c) Kidney (d) Alimentary canal Which of the following is absent in a rat 25. (a) Tonsils (b) Renal portal (c) Gall bladder (d) All of these The kidney in rat are 26. (a) Holonephros (b) Pronephros (c) Mesonephros (d) Metanephros 27. Where do you find Graafian follicles of a rat (a) Ovary (b) Brain (c) Kidney (d) Thyroid 28. Rat is (a) Oviparous (b) Viviparous (d) Parthenogenetic (c) Ovoviviparous Critical Thinking
- Layer of actively dividing cells in skin of frog is termed as 2. stratum [CBSE PMT 1993] (a) Malpighi (b) Corneum (c) Compactum (d) Spongiosum 3. When a frog is transferred from 20°C to 30°C, its body temperature (a) Falls to 15°C (b) Rises to 30°C (c) Falls to 12°C (d) Remain unchanged Which of the following statement is true with reference to teeth in frog (a) The lower jaw is toothless (b) The upper jaw is toothless (c) Both lower and upper jaws are toothless (d) Both lower and upper jaws are toothed Which of the following part is not a part of the small intestine of frog (a) Ileum (b) Jejunum (c) Duodenum (d) None of these In frog, pancreas produces [CBSE PMT 1991] (a) Two digestive enzymes, one hormone (b) Three digestive enzymes, one hormone (c) Three digestive enzymes, two hormones (d) Three digestive enzymes, three hormones Stomach of frog does not have (a) Fundic part (b) Cardiac part (c) Pyloric part (d) All of these Contraction of sternohyal muscles during breathing in frog [CBSE PMT 1992] (a) Closes glottis (b) Opens the nostrils (c) Raises floor of oral cavity (d) Lowers floor of oral cavity Pylangium in frog is found in [CBSE PMT 1990] (a) Atrium (b) Ventricle (c) Sinus venosus (d) Conus arteriosus A spiral valve is present in (a) Sinus venosus of frog's heart (b) Right auricle of rabbit's heart (c) Pylangium of the conus arteriosus of frog's heart (d) Synangium of the conus arteriosus of frog's heart Three chambered heart of frog is not as efficient as fourchambered human heart because [EAMCET 1999] (a) Heart muscles are not strong

Objective Questions

[NCERT: AFMC 1991] Frog has

- (a) 4 fingers in hand and 5 toes in foot
- (b) 5 fingers in hand and 5 toes in foot
- (c) 5 fingers in hand and 4 toes in foot
- (d) 6 fingers in hand and 5 toes in foot

- (b) It does not hold enough blood
- (c) Ventricle does not pump blood properly
- (d) Oxygenated and deoxygenated blood mix up
- Velocity of conduction of nerve impulse in frog is

[CBSE PMT 1991, 93]

- (a) Faster than sound
 - (b) 30 metre per second
- (c) 300 metre per second
- (d) None of these
- Which one of these are never present in frog's ovary 13.
 - (a) Oogonia
- (b) Corpus luteum
- (c) Ovarian follicles
- (d) Germinal epithelium
- 14. There is no gall bladder in
 - (a) Rat
- (b) Horse
- (c) Whale
- (d) All of these

- The clitellum is a distinct part in the body of earthworm, it is 15. [NCERT] found in
 - (a) Segments 13 14 15 (b) Segments 14 15 16

 - (c) Segments 12 13 14 (d) Segments 15 16 17
- Setae help in locomotion in earthworm but not uniformly present in all the segments. Select among the following that [NCERT] represents setae
 - (a) 1st segment
- (b) Last segment
- (c) Clitellar segment
- (c) 20th 22nd segment

Answers and Solutions

Morphology of Frog

- (a) Anura is characterized by the absence of tail, also known as salientia, the Leaping animals.
- (c) The scientific name of common toad is Bufo 5. melanostictus.
- 7. The elevated poison secreting glands or parotid glands are present behind each tympanum of Bufo.
- 9. Being cold blooded or poikilothermous (the body temperature changes with environment) frogs undergo aestivation or 'summer sleep' in summer and hibernation or 'winter sleep' in winter.
- 14. (a) Croaking is a natural voice of frog which is heard more commonly during breeding season. Male frog croaks more loudly because it possesses two vocal sacs over its throat which act as resonators.
- 16. (b) In indirect development, the young ones do not resemble the adults. The young ones usually pass through one or more intermediate stages before obtaining the shape of the adults.
- (b) A pair of internal nares, in the form of two small 23. opening are present on the roof of the buccal cavity lying outer to vomerine teeth.
- (b) The mucous glands secrete a slimy fluid, the mucus, 24. which makes the skin moist and slippery in nature.
- 25. (d) During capacitation sperms undergo acrosomal reaction and release various chemicals contained in the acrosome. These chemicals are collectively called sperm lysin, which dissolve covering membrane of oocyte.
- (d) Just beneath the stratum germinativum there are 26. present many scattered pigment cells (chromatophores) in the stratum spongiosum.
- (a) The skin of frog provides an extensive surface for the 27. exchange of gases (cutaneous respiration).
- (b) Each frog's egg is surrounded by the vitelline 29. membrane (secondary egg membrane) and many layers called tertiary egg membrane of adhesive jelly which were added as it passes through the oviduct or during fertilization.
- (b) Bidder's canal is present in the kidney of male frog. It is 31. helpful in the transfer of sperms from the vasa efferentia
- The pyloric stomach is separated from the duodenum by a 34. muscular construction, the pyloric constriction externally, which indicates the position of pyloric sphincter, which controls the entry of food into duodenum.
- Frog is a positive pressure breather. It fills its lung by 38. forcing air into them, for this, mouth has to be kept closed.
- (b) In frog, cutaneous respiration occurs in water, during 39. hibernation and even aestivation.
- (b) The lungs of frog are two delicate, elastic, pinkish, 43. ovoid, thin walled hollow sacs lying on either side of the oesophagus.

- 45. (b) In frog, the skin serves as an accessory organ of respiration because the skin of frog is thin and richly supplied with blood capillaries. It is kept moist by mucus and water.
- 46. (a) In frog, the cutaneous respiration is always carried out. During winter sleep and summer sleep it is the only method of respiration in frog.
- **48.** (a) RBCs of frog are nucleated, oval and biconvex and have haemoglobin (respiratory pigment).
- 49. (c) Two additional chambers connected to the heart of frog are sinus venosus and truncus arteriosus.
- 50. (a) Sinus venosus is a triangular chamber attached dorsally to heart formed by the union of three main vena cava.
- **52.** (b) Amphibian heart is a three-chambered structure formed by two upper auricles and a single lower ventricle.
- **54.** (a) Mesorchium is a thin mesentery that suspends testis from ventral anterior part of kidney.
- **57.** (c) Frog also possess well developed renal portal system. While it is absent in mammals.
- 62. (d) The fenestra ovalis leads into auditory capsule.
- 63. (c) The main organs of excretion are paired mesonephric kidneys which are compact, dark red and bean like structure situated little posteriorly in the body cavity on both sides of vertebral column.
- **64.** (b) Sclerotic is the outermost layer of eye ball which is fibrous in nature.
- 67. (c) Urinary bladder of frog is a transparent, highly distensible bilobed sac, attached to the ventral side of the cloaca.
- **69.** (d) Embryologically columella auris of frog is homologous to stapes of mammals.
- 70. (d) In the tadpole, the end product of nitrogen metabolism is ammonia which is easily disposed off by diffusion in water. After metamorphosis, the frog excrete most of their nitrogen in the form of urea.
- (a) Presence of external ear or pinna is a typical mammalian character.
- 73. (a) Thin roof of cerebrum in frog is called pallium. This term is also used in reference to mantle of a mollusc or brachiopod.
- 74. (b) The number of spinal nerves is definite in a particular group of animals. In frog the number is ten pairs.
- 76. (a) Optic is second cranial nerve of frog, which carries impulse of sight from the eye to the brain and its nature is sensory.

Morphology of Rat

- (d) Most important character of mammals is the presence of mammary glands (modified sweat glands).
- 3. (a) In male rat, a pair of testes is found in the scrotal sacs.
- 4. (b) Rat is fossorial animal i.e. living in burrows.
- 5. (c) Rattus norvegicus is common brown rat.
- 6. (b) Each limb of rat is made up of proximal segment, the stylopodium, middle segment the zeugopodium and distal segment the autopodium.
- (d) One pair of thoracic nipples, two pairs of axillary nipple, one pair of abdominal nipples and two pairs of inguinal nipples.
- 12. (b) The dental formula of rat is $\frac{1003}{1003} = 16$.
- 13. (c) In haemoendothelial placenta, all the three uterine tissue barriers (foetal connective tissue and trophoblast) are absent with only one placental barrier. e.g. rabbit, rat and guinea pig.

- (a) Diastema is a natural toothless space in mammals, in rat found between incisor and molar teeth.
- (d) Like other mammals rat possess closed and double circulation.
- **20.** (a) The time interval between fertilization and birth (gestation period) is about 22 to 23 days.
- **21.** (d) Fertilization is internal and takes place in the dilated uppermost portion of the fallopian tube.
- **22.** (b) The brain is protected by three membrane known as meninges.
- **24.** (d) Hepatic portal system is well-developed in mammals. The food-laden blood from various region of the digestive tract is collected by four vein
 - (i) lienogastric from stomach and spleen
 - (ii) Duodenal from duodenum
 - (iii) Anterior mesentric from small intestine, caecum and colon.
 - (iv) Posterior mesenteric from rectum.
- **26.** (d) The functional kidney of higher vertebrates or amniotes is a metanephros.
- **27.** (a) Graafian follicle is a matured ovarian follicle, which is found in the mammalian ovary.

Critical Thinking Questions

- (a) In frog, the fore limbs are shorter and stouter, end in four digits and the hind limbs are much larger and muscular than the forelimbs, end in five digits.
- (a) The cells of stratum malpighi of frog are continue growing and divide mitotically throughout life to form new layer being pushed towards the surface successively.
- (a) The lower jaw of frog is toothless. Teeth are present on premaxillae, maxillae of upper jaw.
- (b) Stomach is followed by a coiled small intestine made of a small anterior duodenum and much longer posterior ileum. Jejunum is absent in frog.
- 6. (b) In frog, pancreas is made up of lobules, connective tissue and islets of langerhans. The islets of Langerhans secrete a hormone known as insulin. The pancreatic juice contains three enzymes. The trypsin, amylopsin and steapsin or lipase.
- 7. (a) Stomach of frog comprises a large broader anterior part called cardiac stomach and a short narrower posterior part called pyloric stomach. Fundic stomach is absent.
- (d) Throat is lowered and raised alternatively by sternohyal and petrohyal muscles.
- (d) Truncus arteriosus of frog is divided into a long basal thick walled conus arteriosus or pylangium and a short distal thin walled bulbous aorta or synangium.
- 10. (c) A large twisted spiral valve divides incompletely the cavity of pylangium into a left dorsal cavum pulmocutaneum and right ventral cavum aorticum.
- (b) Corpus luteum, an endocrine structure, is formed in the mammalian ovary from ruptured Graafian follicle after ovulation.
- **14.** (d) Gall bladder is absent in rat (also in whales, some artiodactyla and all perissodactyla).

ET Self Evaluation Test

- During breeding season, nuptial pad is found in the thumb
 of
 - (a) Male frog
- (b) Female frog
- (c) Both of these
- (d) None of these
- 2. The glands present in the skin of frog are

[NCERT; AFMC 1993]

- (a) Sweat and mucous
- (b) Sweat and mammary
- (c) Mucous and poisonous
- (d) Sweat and sebaceous
- 3. The structure present is man but absent in frog is

[NCERT; AFMC 2001]

- (a) Pancreas
- (b) Thyroid gland
- (c) Adrenal gland
- (d) Salivary gland
- The epithelial lining of the alveoli of frog's lungs facing lung cavity is [CBSE PMT 1990]
 - (a) Columnar and ciliated
 - (b) Squamous and ciliated
 - (c) Squamous and nonciliated
 - (d) Columnar and nonciliated
- 5. RBCs of rat are
 - (a) Small, round, nonnucleated and biconcave
 - (b) Small, round, nonnucleated and biconvex
 - (c) Small, oval, nonnucleated and biconcave
 - (d) Small, round, nucleated and biconcave
- 6. The jaws, eye orbits and nasal chambers in frog are supplied by
 - (a) Occipital arteries
 - (b) Vertebral arteries
 - (c) External carotid arteries
 - (d) Internal carotid arteries
- 7. Which one is the correct statement in regard to frog

[CBSE PMT 1993]

- (a) Fertilization occurs in uteri
- (b) Ova from ovary are shed into infundibuli, pass through oviducts and stored in uteri
- (c) Testes develop inside kidney, so that sperms are able to reach the urinogenital ducts
- (d) Male and female frogs are similar but gonads appear at the time of reproduction
- 8. Anterior abdominal vein in frog is formed by union of

[CBSE PMT 1991; AMU (Med.) 2009]

- (a) Right and left pelvic veins
- (b) Right and left sciatic veins
- (c) Right and left femoral veins
- (d) Right and left dorsolumbar veins
- Which of the following is true of hibernating gland in rat
 - (a) It is gland formed during hibernation
 - (b) It secretes digestive enzymes to metabolise fat
 - (c) It secretion regulate the body temperature during winter sleep
 - (d) It is not a gland at all, but a multicellular adipose tissue

- 10. Glands of Swammerdam are related with
 - (a) Spinal nerves of frog
- (b) Cranial nerves of frog
- (c) Endocrine system of frog (d) Alimentary canal of frog
- 11. Bidder's canal is meant for passage of

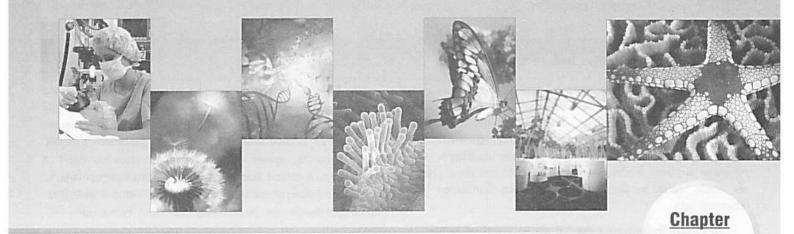

INCERTI

- (a) Ova
- (b) Urine
- (c) Sperms
- (d) All of these

Answers and Solutions

1	a	2	С	3	d	4	a	5	a
6	a	7	b	. 8	a	9	d	10	a
11	С								

- (a) Frog exhibit sexual dimorphism. Male and female are
 distinguishable externally only during breeding season
 when the male develop roughed nuptial pads on the
 bases of the thumb. Nuptial pads help male in holding
 female, a sexual embrace called amplexus.
- (c) Skin is soft, moist and slimy consists of epidermis and dermis. Mucous glands and poison glands are present in the dermis and their ducts open at the surface.
- 3. (d) Frog has no salivary glands.
- (a) Ciliated columnar epithelium comprises columnar cells which have cilia on free surface. This epithelium lines most of the respiratory tract and fallopian tubes.
- (a) RBCs of rats are small round, nonnucleated and biconcave containing red coloured respiratory pigment namely haemoglobin.
- (a) The occipital artery in front supplies jaws, eye orbit and nasal chambers. It is a branch of occipito-vertebral artery.
- (a) The pelvic veins of both sides unite to form a median ventral or anterior abdominal vein. It receives blood from urinary bladder and ventral abdominal wall.
- (d) A fatty mass of pinkish colour, located in the region between the scapulae and neck of rat is often called hibernating gland.
- 10. (a) Glands of swammerdam are soft chalky masses of calcareous bodies found in the dorsal root ganglion of spinal nerve in frog. These form reserve supplies of calcium.
- (c) Bidder's canal is present in the kidney of male frog. It is helpful in the transfer of sperms from the vasa efferentia to water.

3.1

Microscopy

Microscopy (Gk. Micros = small; skopein = to see) is practice of using microscopes for the study of finer details of small objects including cells and tissues. Microscope are instruments consisting of lenses (made of glass / Lithium fluoride / electromagnetic lens) which magnify and resolve small objects not visible to unaided eye for the study of their details. The term microscope was coined by Faber in 1625.

Magnification: It is the degree of enlargement or the ratio of size of the object as seen in the microscope to its actual size.

 $Magnification = \frac{Size \text{ of the image with the instrument}}{Size \text{ of the image with unaided eye}}$

Magnification of a microscope is roughly equal to the multiple of magnifying power of objective lens and ocular lens (eye piece) e.g., if the magnification power of an ocular lens is $10 \, X$ and of the objective is $40 \, X$, then the total magnifying power of a microscope is $10 \times 40 = 400 \, X$ (the magnification power of a microscope is represented by the symbol 'X').

Resolving power: It is the ability of a system to distinguish two close objects as two distinct objects. Its value is calculated by *Abbe* equation –

$$L_m = \frac{0.61\lambda}{NA}$$

Here, λ – is wavelength of used light, NA – Numerical Aperture, $(NA = n \sin \theta)$

Numerical aperture is multiple of refractive index of medium (n) and $\sin\theta$, which is sine of angle substended by optical axis and outer ray covered by objective. The value for best objective sine $70^{\circ} = 0.94$.

Resolving power of a light microscope ranges from $0.2\mu m$ to $0.4\mu m$ in blue light.

The resolving power of human eye is $100\mu m$ or microns (0.1 mm). This means that two points less than $100\mu m$ apart appear as one point to our eyes.

Father of microscopy is *Leeuwenhoek*. He built first 270 X magnification microscope in 1672.

Types of microscopes

(1) **Simple microscope**: It is also known as magnifying glass and consists of a convergent lens.

Leeuwenhoek (1683) designed a primitive microscope and discovered cells with it. It was the first tool ever used to observe biological objects. Its magnification power was 14-42 times only, so it is considered as simple microscope.

(2) Compound microscope or Light microscope: The first compound microscope was assembled by Zacharias Janssen and J. Janssen, the Dutch spectacles makes in 1590. The compound microscope was prepared by Kepler and Galileo in 1611. However, it was not used for laboratory study. It is simplest, widely used microscope having three lens i.e., condensor, which collects the light rays and precisely focuses them on the objects; objective lens, which magnifies the image by three objective lenses, i.e., low power (10x), high power (45x) and oil immersion lenses.

In a compound microscope an object can be magnified upto 1000 times and the magnification is independent of intensity of light, size of microscope and numerical aperture. The light microscope is also called *bright field* microscope because it forms the image when light is transmitted through the object.

- (3) Fluorescent microscope: It was developed by Coons (1945). It is observed that when ultraviolet light is irradiated on certain chemical substances, they absorb it and emit visible light. These chemical substances are called fluoro-chromes. The fluorescent substances e.g., quinine sulphate, rhodamine and auramine are used to stain the cellular objects and these objects are easily visible as fluorescent areas when illuminated with ultraviolet light.
- (4) **Polarizing microscope**: It was invented by *Tolbart*. In this microscope the plane polarised light is used as a source of illumination. Unlike the ordinary light, plane polarised light vibrates only in one direction and the cellular objects are easily visible as they appear bright against the dark ground. Polarizing microscope is helpful in studying the spindle fibres in the cells.
- (5) **Ultraviolet microscope**: It was invented by *Caspersson*. In this microscope the source of illumination is ultraviolet radiations having shorter wavelengths (1500 Å 3500 Å) as compared to ordinary visible light. In this microscope, the lenses are made of fluoride, lithium fluoride or quartz instead of glass.

Ultraviolet microscope is helpful in quantitative determination of all those cell components which absorb ultraviolet rays.

(6) Phase contrast microscope

- (i) Discovered by Dutch man Fredericke Zernicke (1935).
- (ii) Source of illumination is visible light.
- (iii) It is used to study living cells and tissues without staining and effect of chemical and physical agents on the living cells.
- (iv) It is also used to study spindle formation, pinocytosis, karyokinesis, cytokinesis etc.
- (v) The demerit of this microscope is subcellular organelles smaller than $0.2\,\mu$, (like ribosomes, lysosomes, ER) cannot be visualised.

(7) Interference microscope (Morten et.al.)

- (i) It's principle is similar to that of the phase contrast microscope and gives / studies quantitative data.
- (ii) Nomarski interference contrast microscope is useful to study mitosis /cell components in living state.
- (iii) It gives better image of living structures. It is also used to measure thickness of the cell and determination of several light absorbing chemicals like nucleic acid, proteins, lipids etc.

(8) Dark field microscope

- (i) Zsigmondy (1905) invented this microscope.
- (ii) It is based on the fact that light is scattered at boundaries between regions having different refractive index.
- (iii) The object smaller than those seen with ordinary light microscope can be detected but can not be resolved.

(9) **Electron microscope**: This was developed by *M. Knoll* and *E. Ruska* (1931) in Germany. It is the best device to determine the ultrastructure of a cell organelle. It is a large sized instrument which has an internal vacuum, high voltage (50,000 – 1,00,000 volts), a cooling system, a fast beam of electrons (0.54 Å wavelength), a cathod filaments of tungsten and electromagnetic lens (which having a coil of wire enclosed in soft iron casing) for focusing. Ribosomes can be seen only in electron microscope.

Thus an electron microscope essentially comprises an electron gun and electron lenses. The electron gun is the source of electrons consisting of a heated tungsten filament. It is preferred because it can be heated upto 3000°C. The electron beam can be reflected by magnetic field. Therefore, a very powerful magnetic coil acts as lens. The focal length of the electromagnetic lenses change with the wavelength of illumination. Since the wavelength is controlled by the voltage, it should be controlled and made constant. Three types of magnetic lenses are used namely projector, objective and condenser. The magnetic field produced is concentrated by soft iron casing. When the filament is heated to incandescence, it emits electron. The electrons then move to positively charged anode. The entire microscope column operates under conditions of high vacuum. It is due to this fact that we can not observe living objects through an electron microscope (EM). For viewing objects under EM, ultrathin sections (20-100 nm thick) are prepared through an ultramicrotone. It was first developed by W.His.

Electron microscope can magnify the objects upto 2,00,000 times (now possible upto 2,50,000-4,00,000) and direct study of objects is possible on this microscope. The resolving power of electron microscope is 10~Å which is 100~times more than the light microscope. Study of living cells can not be done through this microscope because of high voltage, which is required to operate it, kills the living materials. Electron microscope are of two types :

(i) **Transmission electron microscope (TEM)**: It was the first microscope developed by *Ruska* (1932). It produces two dimensional images.

Magnification of TEM is 1–3 lakh and resolving power is 2–10Å. Because of them transmission electron microscope has helped in the discovery of a number of small cell organelles e.g., ER, ribosomes, centrioles, microtubules etc. Detail structure of larger cell organelles could also be known only with the help of TEM. e.g., chloroplast (thylakoids), mitochondria (elementary particles, DNA), ribosomes etc.

(ii) Scanning electron microscope (SEM): This microscope was invented by Knoll (1935).

It gives three dimensional image. The specimen to be studied is first super cooled (in liquid propane at $-180^{\circ}C$) and dehydrated in alcohol (at $-70^{\circ}C$). It is then coated with gold, platinum or some other metals for creating a reflecting surface for electrons. Magnification of SEM varies from 15-2,00,000. Resolution power is 5-20 nm.

(10) Advanced high power microscope

- (i) **Scanning probe microscope**: The microscope is capable of resolving the outer texture of the material to the minutest detail since it has the potential to image even a single atom. Magnification is upto 100 million.
- (ii) Scanning tunnelling microscope: It has a tiny tungsten probe for moving over the surface of specimen. The microscope is used to detect defect in electrical conductors and computer chips.
- (iii) Atomic force microscope: It has an extremely fine diamond probe for moving over the surface of biochemicals. Oscillations produced in the probe are changed into images by a computer.

The microscope is useful in viewing detailed structure of biological molecules, e.g., DNA, proteins, etc.

Units of measurement used in microscopy

1 micron (μ) = 10^{-6} or one millionth

1 micrometer (μm) = 10^{-6} m, 10^{-4} cm, 10^{-3} mm = 1000 nm

1 Nanometer $(nm) = 10^{-9} m$, $10^{-7} cm$, $10^{-6} mm$, $10^{-3} \mu m = 10 Å$

1 Angstrom (Å)= 10^{-10} m, 10^{-8} cm, 10^{-7} mm, 10^{-4} μ m,

1 Picometer $(pm) = 10^{-12} m, 10^{-3} nm$

1 Femtometer (fm) = 10^{-15} m, 10^{-6} nm

1 Attometer = $10^{-18} m$, $10^{-9} nm$

Common unit of measurement in Microscopy and cytology is nanometer while unit of measurement of cell is micron.

Cytochemistry

A number of dyes or stains are known to colour specific parts. Certain dyes can be used even in case of living materials. They are called vital stains, e.g., neutral red, methylene blue.

Fuelgen or Schiff's reaction was developed by Fuelgen and Rossenbeck (1924). Identification and localization of chemical compounds of a cell is studied in cytochemistry.

Table: 3.1-1 Some important cytochemical stains

Stain	Used for staining	Final colour	
Acetocarmine	Chromosomes	Pink	
Acid fuchsine	Cortex, cellular walls, mitochondria	Magenta	
Aniline blue	Fungal hyphae	Blue	
Basic fuchsine	Nucleus	Magenta red	
Crystal violet	Bacteria	Violet	
Eosin	Cytoplasm	Pink	
Feulgen's stain	DNA	Purple/Red	
Hemotoxyline	Nuclei, cell wall, cellulose	Violet	
lodine solution	Starch	Blue	

Janus green	Fungi and mitochondria	Green
Methylene blue	Yeast and Golgi complex	Blue
Phloroglucinol +HCl	Lignin	Red
Ruthenium red	Pectin	Red
Safranin	Nuclei, lignified tissue	Red
Sudan- III or IV	Suberin, cutin, oil	Red
Sudan black	Fatty substance	Black
Toludine blue	RNA	Blue
Cotton blue	Fungi	Violet

Cell fractionation

In isotonic medium cell components are separated, in two steps process.

Homogenisation : Cell products are separated in isotonic medium (0.25 M sucrose solution) either with the help of homogeniser of ultrasonic vibrations kept at $0-4^{\circ}\text{C}$. A homogenised cell is called homogenate.

Differential centrifugation: Homogenisation product is rotated (centrifuged) at different speeds. The sediment or pellete of each speed is collected. e.g., nuclei at $1000 \times g$ (g= force of gravity) for 10 minutes, chloroplast and mitochondria at $10,000 \times g$ for 15 minutes. The particle settle according to their sedimentation ratios. Sedimentation coefficient is expressed in svedberg unit 'S' related with molecular weight of the particles. For the detail study of mitochondria it is the best technique. 'S' is measured by analytical centrifugation.

The various cell organelles and macromolecules sediment in the following order.

 $Nucleus \rightarrow Chloroplast \rightarrow Mitochondria \rightarrow Ribosome \rightarrow DNA \rightarrow mRNA \rightarrow tRNA$

Chromatography

Discovered by Michael Tswett (1906). This technique is used to separate the molecules of different substances present together. Mixture of molecules is run over an adsorption medium. Chromatography may be following types.

Adsorption or Column chromatography: The stationary phase consists of a column of charcoal, silica, alumina, calcium carbonate or magnesium oxide. The solution is made to percolate through this column when different chemicals get absorbed at various levels. The technique is useful for separation of tissue lipids.

Thin layer chromatography (TLC): The stationary phase consists of a thin plate of cellulose powder or alumina. As a few drops of mixture are poured over it, the different chemicals spread to different distances. The method is useful in separation of amino acids, nucleotides and other low molecular weight products.

Paper chromatography: A paste of mixture is applied near one end of a chromatographic paper (or Whatman 1). The lower end below the paste is dipped in a solvent. As the solvent rises in chromatographic paper, the different chemicals of the mixture spread to different distances. The paper can be rotated to obtain two dimensional chromatogram.

Types: (a) Ascending (b) Descending (c) 2-D chromatography.

Ion exchange chromatography: Beads of cellulose and other materials having negative and positive charges are placed in a column. The mixture (mobile phase) is poured over the column. As the mixture passes through the column, its constituents separate according to their charges. The technique is used in purification of insulin, plasma fractionation and separation of proteins.

Gel fractionation / Gel filtration chromatography (Molecular sieve chromatography): The stationary phase consists of gel forming hydrophilic beads which contain pores, e.g., sephadex (cross-linked dextran). As the mixture is poured over the gel, larger molecules pass out unimpeded while small molecules are trapped in the pores. The technique is used in separation of proteins. It is also employed in determining their molecular weight by calibrating the column with proteins of known molecular weight.

Affinity chromatography: Stationary phase consists of column of ligands (molecules that bind to other specific molecules at particular sites).

Mixture is allowed to pass through the column. Chemical linkages are established between ligands and their specific chemicals. Others pass out of the column. The technique is used in separation of enzymes, immunoglobulins, mRNA, etc.

Electrophoresis

It is an another technique of separation in which patricles of different charges and sizes are separated under the influence of electric field. e.g., nucleic acids, proteins, amino acids, nucleotides can be separated by this method. The technique was discovered by Russian physicist Alexender Reuss in 1807.

Autoradiography

It is a technique of studying the route of chemicals in chemical reactions taking place inside the cell and organisms with the help of radioactive isotope. *e.g.*, ¹⁴C, ³H, ³²P.

In this technique the radioisotopes are incorporated into the precursor molecule. Then the labelled precursor molecules introduced into the cells and their path is followed with the help of their radiations.

Radioactive precursors emit radiations and their position in the cell is located by bringing the cell in contact with a photographic plate or film.

 ^{32}P and ^{14}C are used for the study of nucleic acids and photosynthesis (Melvin Calvin) respectively.

Radioisotope or Tracer technique

They are unstable isotopes which function like normal elements but emit positive or negative particles, e.g., ³H (Tritium), ¹⁴C (Carbon), ³²P (Phosphorus), ³⁵S (Sulphur), ⁴²K (Potassium), ¹³¹I (Iodine). Radioactivity is recorded in different parts by Geiger counter or scintillation counter or autoradiography to know regions of use and transport. The tracers have been used for knowing pathway of mineral transport (Stout and Hoagland, 1939), organic solute transport (Vernon and Aronoff, 1952), carbon assimilation (Calvin, 1955).

Where radioactive elements are not available, heavy isotopes are used, e.g., ^{15}N , ^{18}O . Their fate is recorded by mass spectroscopy and density gradient centrifugation. Meselson and Stahl (1958) studied DNA replication and Ruben et al (1941) evolution of oxygen (photolysis of water) in photosynthesis by using heavy isotopes.

X-ray crystallography

It was developed by the *Bragg* (1913). They can be used as a tool for determining the arrangement of atoms in various biological molecules.

By using this technique Wilkins et al., 1953 found out details of the DNA molecule for which he was also awarded Nobel Prize along with Watson and Crick in 1962. Kendrew, 1957 by using the same technique studied the molecules of myoglobin.

Cell as a unit of life

Cytology (Gk *Kytos* = cell; *logos* = study): It is the branch of biology, which comprises the study of cell structure and function. "Cell is the structural and functional unit of all living beings". Study of metabolic aspects of cell components is called cell biology.

Robert Hooke (1665) discovered hollow cavities (empty boxes) like compartments in a very thin slice of cork (cell wall) under his microscope. He wrote a book "Micrographia" and coined the term cellula, which was later changed into cell. Grew and Malpighi also observed small structures in slice of plants and animals. Leeuwenhoek was the first to see free cells and called them "wild animalcules" and published a book "The secret of nature". He observed bacteria, protozoa, RBCs, sperms, etc. under his microscope.

Cell theory: H.J. Dutrochet (1824) a French worker gave the idea of cell theory.

The actual credit for cell theory goes to two German scientists, a Botanist M.J. Schleiden (1838) and a Zoologist T. Schwann (1839). They gave the concept "all living organisms are composed of cell". Schleiden and Schwann both supported the theory of "spontaneous generation". They also mentioned that "the new cell arises from nucleus by budding".

Exceptions to the cell theory: Viruses, viroids and prions are an exception to the cell theory as they are obligate parasites (sub-cellular in nature).

Modification of cell theory: Modification of cell theory was done by Rudolf Virchow (1855). He proposed the "law of cell lineage" which states that cell originates from pre-existing cells. i.e., (omnis cellula-e-cellula). It is also called "cell principle" or "cell doctrine". It states:

- (1) Life exists only in cells.
- (2) Membrane bound cell organelles of the protoplasm do not survive alone or outside the protoplasm.
- (3) Cells never arise de novo. The new cells are like the parent cell in all respect.
- (4) All cells have similar fundamental structure and metabolic reactions.
 - (5) Cells display homeostasis and remain alive.

- (6) Genetic information is stored in DNA and expressed within the cells.
 - (7) DNA controls structure and working of a cell.

The cell as a self contained unit: Autonomy of a cell is believed due to presence of DNA and its expressibility, otherwise, cell components have different shape and function. It has two positions.

- (1) Autonomy in unicellular organisms: Unicellular organisms leads to a totally independent life due to different shape, size and role of different organelles shows division of labour. All these display homeostasis. Unicellular organisms are more active due to large surface volume ratio.
- (2) Autonomy in multicellular organisms: In multicellular organisms life activities are displayed by each of the cells independently. Multicellular organisms have one thing advantage over unicellular organisms is division of labour.

Cellular totipotency: Totipotency was suggested by Haberlandt (1902). When cells have tendency or ability to divide and redivide the condition of the cell is called totipotent and this phenomenon is called totipotency. Steward et.al. showed the phenomenon of cellular totipotency in phloem tissue of carrot.

Surface volume ratio: Metabolically active cells are small, as small cells have higher nucleocytoplasmic ratio for better control and higher surface volume ratio for quicker exchange of materials between the cell and its outside environment. Larger cells have lower surface volume ratio as well as lower nucleocytoplasmic ratio. Surface volume ratio decreases if cell size increases.

Table: 3.1-2 Differences between plant and animal cell

Plant cell	Animal cell
Cell wall present.	Cell wall absent.
Nucleus usually lies near periphery due to vacuole.	Nucleus present near the centre.
Centrosome is usually absent from higher plant cells, except lower motile cells.	Usually centrosome is present that helps in formation of spindle fibres.
Plastids are present, except fungi.	Plastids are absent.
Mitochondria is generally spherical or oval in shape.	Generally tubular in shape.
Single large central vacuole is present.	Many vacuoles occurs, which are smaller in size,
Cytoplasm during cell division usually divides by cell plate method.	Cytoplasm divides by furrowing or cleavage method.
Plant cells are capable of forming all the amino acids, coenzymes and vitamins.	Animal cells cannot form all the amino acids, coenzymes and vitamins.
There is no contractile vacuole.	Contractile vacuole may occur to pump excess water.
Spindle formed during cell division is anastral.	Spindle formed during cell division are amphiastral.
Lysosomes present in less number.	Lysosomes present in more number.

Types of cells

Chatton gave the term prokaryote and eukaryote. Depending upon the nature of nucleus, cells are classified. Incipient nucleus is present in prokaryotes, where as in eukaryotes well organised nucleus is present.

Table : 3.1-3
Differences between prokaryotic and eukaryotic cell

Prokaryotic cell	Eukaryotic cell	
It is a single membrane system.	It is a double membrane system.	
Cell wall surrounds the plasma membrane.	Cell wall surrounds the plasma membrane in some protists most fungi and all plant cell. Animal cell lacks it.	
Cell wall is composed of peptidoglycans. Strengthening material is murein.	It is composed of polysaccharide. Strengthening material is chitin in fungi and cellulose in other plants.	
Cell membrane bears respiratory enzymes.	It lacks respiratory enzymes.	
Cytoplasm lacks cell organelles e.g., Mitochondria, ER, Golgi body etc.	Cytoplasm contains various cell organelles.	
Ribosomes are only 70 S type.	Ribosomes are both 80 S and 70 S type.	
There are no streaming movements of cytoplasm.	Cytoplasm show streaming movements.	
Nuclear material is not enclosed by nuclear envelope and lies directly in cytoplasm. It is called nucleoid.	It is enveloped by nuclear envelope. Nucleus is distinct from cytoplasm.	
DNA is circular and not associated with histone proteins.	Nuclear DNA is linear and associated with histone proteins extranuclear DNA is circular and histone protein free.	
Sexual reproduction absent but parasexuality present.	Sexual reproduction is present.	
Cell division mostly amitotic.	Cell division is typically mitotic.	

Mesokaryon: Dodge gave the term 'Mesokaryon' for dinoflagellates. These are intermediate type of cell organisation in dinophyceae of algae. In mesokaryotic there is present a true or eukaryotic nucleus with definite nuclear membrane and chromosomes.

Cell wall

Discovery: It was first discovered by *Robert Hooke* in 1665 in Cork. Cell wall is the outer most, rigid, protective, non living and supportive layer found in all the plant cells, bacteria, cyanobacteria and some protists. It is not found in animal cells.

Chemical composition: Mainly cell wall consists of two parts, matrix and cellulosic fibres (microfibrils). Matrix consists of hemicellulose, pectin, glycoproteins, lipids and water. In most of the plants cell wall is made up of cellulose $(C_6H_{10}O_5)_n$, a polymer made-up of unbranched chain of glucose molecule linked by $\beta 1-4$ glycosidic bond. About 100 molecules of cellulose form a microfibril about 20 micelle form a microfibril and approx. 250 microfibril form a fibril.

UNIVERSAL BOOK DEPOT 1960

The cell wall of bacteria and the inner layer of blue green algae is made-up mucopeptide. It is a polymer of two amino sugars namely N-acetyl glucosamine (NAG) and N-acetyl muramic acid (NAM) held alternately in β -1,4- linkage. In higher fungi, the cell wall is made up of chitin, polymer of glucosamine.

Structure: Cell wall consists of middle lamella, primary wall, secondary wall, tertiary wall.

(1) Middle lamella: Middle lamella is the outermost region which functions as a common cementing layer between two cells. It is absent on the outer free surface. It ruptures to create intercellular spaces. Middle lamella is formed of calcium and magnecium pectate. Calcium pectate is main component of middle lamella. Fruit softening is due to gelatinisation of pectic compounds of middle lamella. Pectin is used as commercial jellying agent, which is present outside the primary wall.

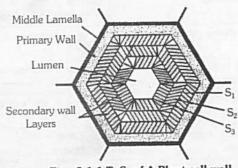

Fig: 3.1-1 T. S. of A Plant cell wall

- (2) Primary wall: A young plant cell forms a single layer of wall material. This layer is known as the primary cell wall. The primary wall is thin, elastic and capable of expansion in a growing cell. It grows by intussusception. Meristematic and parenchymatous cells have primary cell wall only. The cells of leaves and fruits too have only primary wall. It has more hemicellulose and less cellulose.
- (3) **Secondary wall**: In mature cell, more layers of wall material are added internal to the primary wall. These are called the secondary cell wall. Growth by addition of new wall material on the primary wall is called accretion. It has more cellulose and less hemicellulose. The secondary wall is thick and rigid. It usually consists of three layers, which are often named S_1, S_2 and S_3 . It is found in collenchyma and sclerenchyma cells, xylem vesseles.
- (4) Tertiary wall: Sometimes tertiary wall is laid down on secondary wall, e.g., tracheids of gymnosperms. It is composed of cellulose and xylan.
- Origin: A cell wall is organise at telophase stage of cell division. The plane and place of cell wall is determined by the microtubules. Fragments of ER and vesicles of golgi body aligned at the equator, called as phragmoplast, later which forms the cell plate. The synthesis of cellulose takes place by the help of enzyme cellulase synthetase present in the plasma membrane. The cell plate forms the cell wall. Beside these, different materials are deposited as:

- (i) Lignin: It is special type of polysaccharide which deposits mainly in xylem cells and makes them hard and lignified. Due to its deposition xylem tracheids take up different forms, e.g., annular thickening, spiral thickening, scalariform thickening.
- (ii) Cutin: It is a wax-like fatty substance. It is deposited on the epidermal cells in the form of cuticle which reduces loss of water. Cuticle is very thick in xerophytes, thin in mesophytes and absent in hydrophytes.
- (iii) Suberin: It is a complicated mixture of fatty acids deposited on cork cells. Suberin is impermeable to water.
- (iv) **Mucilage**: Some cells are slippery to touch due to secretion of mucilage, e.g., blue-green algae. The cells can withstand extremes of temperature, i.e., very low or very high.
- (v) Silica: In some cases sand or silica particles are deposited which give a rough touch, e.g., Equisetum and Saccharum munja.

In family Moraceae, Urticaceae, Cucurbitaceae and Acanthaceae, Ca oxalate and Ca carbonate crystals are deposited.

Growth of cell wall

- (1) By intussuception: As the cell wall stretches in one or more directions, new cell wall material secreted by protoplasm gets embedded within the original wall.
- (2) By apposition: In this method new cell wall material secreted by protoplasm is deposited by definite thin plates one after the other.

Thickenings of cell wall: In many secondary walls specially those of xylem the cell wall becomes hard and thick due to the deposition of lignin. With the increasing amount of lignin, deposition protoplasm is lost. First the lignin is deposited in middle lamella and primary wall and later on in secondary wall.

- Pits: Secondary walls may have irregular thickenings at some places and these places are called pits. Pits are of five types:
 - (1) Simple pit: In which pit chamber is uniform in diameter.
- (2) Bordered pit: In which pit chamber is flask shaped in tracheids of gymnosperm and vessels of angiosperms.
- (3) **Blind pit**: A pit without any corresponding pit on the adjacent wall is called blind pit.
- (4) Half bordered pit: A pit with half border and the rest half with a simple pit.
- (5) Aspirated pit: It is a non-functional pit in which the pit aperture is blocked permanently by torus.

Plasmodesmata: Tangle (1879) first of all discovered them and were studied elaborately by Strasburger (1901). A number of plasmodesmata or cytoplasmic strands are present in pit through which the cytoplasm of one cell is in contact with another. Endoplasmic reticulum plays a role in origin of plasmodesmata.

Functions of cell wall

- (1) It maintains shape of the plant cells and protect the cells from mechanical injury.
- (2) It wards off the attacks of pathogens (viruses, bacteria, fungi, protozoans).

- (3) It provides mechanical support against gravity. It is due to the rigid cell wall that the aerial parts of the plants are able to keep erect and expose their leaves to sunlight.
- (4) The cell wall prevents undue expansion of the cell when water enters by osmosis to compensate for the lack of contractile vacuole. This prevents bursting of cells.
- (5) Though permeable, the cell wall plays some regulatory role on the passage of materials into and out of the cell.
- (6) Pores in the cell walls permit plasmodesmata to link up all the protoplasts into a system called symplast (symplasm).
- (7) Cell wall and intercellular spaces constitute a nonliving component of plant body known as apoplasm.

Plasma membrane

Every living cell is externally covered by a thin transparent electron microscopic, elastic regenerative and selective permeable membrane called plasma membrane. It is quasifluid in nature. Membranes also occur inside the cells. They are collectively called biomembranes. The term cell membrane was given by C. Nageli and C. Cramer (1855) for outer membrane covering of the portoplast. It was replaced by the term plasmalemma by Plower (1931).

Chemical composition: Proteins lipoprotein (Lipid +Protein) are the major component forming 60% of the plasma membrane. Proteins provide mechanical strength and responsible for transportation of different substances. Proteins also act as enzyme. Lipids account may 28%-79% depending upon the type of cell and organism involved (in humans, myelin 79%). The lipids of plasma membrane are of three types namely phospholipids, glycolipids and sterols. The sterol found in the membrane may be cholesterol (Animals), phytosterol (Plants) or ergosterol (Microorganisms).

Carbohydrates form 2%–10%. Oligosaccharides are the main carbohydrates present in plasma membrane. The carbohydrates of plasma membrane are covalently linked to both lipid and protein components.

Ultrastructure: Under electron microscope the plasma membrane appears three layered, *i.e.*, trilaminar or tripartite. One optically light layer is of lipid and on both sides two optically dense protein layers are present.

Molecular structure and different models : Several models have been proposed to explain the structure and function of the plasma membrane.

- (1) **Overton's model**: It suggests that the plasma membrane is composed of a thin lipid single layer.
- (2) **Sandwitch model**: It was proposed by Davson and Danielli (1935). According to this model the light biomolecular lipid layer is sandwitched between two dense protein layers (globular α type protein). This model was also said to be unit membrane hypothesis.

(3) **Robertson's unit membrane model**: It states that all cytoplasmic membranes have a similar structure of three layers with and electron transparent phospholipid bilayer being sandwitched between two electron dense layer of proteins (extended or β type protein).

Its thickness is about 75 Å with a central lipid layer of 35 Å thick and two peripheral protein layers of 20 Å thick.

(4) Fluid mosaic model: The most important and widely accepted latest model for plasma membrane was given by Singer and Nicolson in 1972. According to them it is "protein iceberg in a sea of lipids."

According to this model, the cell membrane consists of a highly viscous fluid matrix of two layers of phospholipid molecules. Protein molecules occur as separate particles asymmetrical arranged in a mosaic pattern.

Some of these are loosely bound at the polar surfaces of lipid layers, called peripheral or extrinsic proteins. Others penetrate deeply into the lipid layer called integral or intrinsic proteins. Some of the integral proteins penetrate through the phospholipid layers and project on both the surface. These are called trans membrane or tunnel proteins (glycophorins). Singly or in groups, they function as channels for passage of water ions and other solutes.

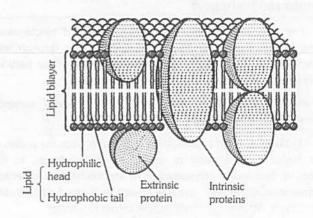

Fig: 3.1-2 Fluid-mosaic model of the plasma membrane structure

The carbohydrates occur only at the outer surface of the membrane. Their molecules are covalently linked to the polar heads of some lipid molecules (forming glycolipids) and most of the proteins exposed at outer surface (forming glycoproteins). Through glycoproteins, bacteria recognise each other. e.g., female bacteria are recognised by male bacteria.

Modification of plasma membrane

- (1) **Microvilli**: They are finger like evaginations of 0.1 μm diameter, engaged in absorption. *e.g.*, intestinal cells, hepatic cells, mesothelial cells. The surface having microvilli is called striated border or brush border.
- (2) **Lomasomes**: They are plasmalemma foldings found in fungal cells. These were reported by Moore and Maclean.

- (3) Mesosomes: It serves as site for cellular respiration in prokaryotes.
- (4) **Tight junctions or (Zonulae occludents)**: Plasma membrane of two adjacent cells are fused at a series of points with a network of ridges or sealing strands. *e.g.*, capillaries, brain cells collecting tubules etc.
 - (5) Desmosomes: Concerned with cell adherence.
- (6) Transosomes: It is found in follicular cells of ovary of birds and have triple unit membrane. First reported by Press (1964).

Functions

- (1) It not only provides mechanical strength but also acts as a protective layer.
- (2) Plasma membrane is responsible for the transportation of materials, molecules, ions etc.
 - (3) It helps in osmoregulation.
- (4) Diffusion of gases (O_2 and CO_2) take place through plasma membrane by simple and facilitated diffusion.
- (5) Water as well as some solute molecules and ion pass through membrane pores; pores are always bordered by channel proteins.

Membrane transport

It is passage of metabolites, by-products and biochemicals across biomembrane. Membrane transport occurs through four methods–passive, facilitated, active and bulk. Size of the particles passing through plasmalemma is generally $1-15\,\text{Å}$.

Passive transport: No energy spent. Passive transport occurs through diffusion and osmosis.

- (1) Diffusion: It is movement of particles from the region of their higher concentration or electrochemical potential to the region of their lower concentration or electrochemical potential. Electrochemical potential operates in case of charged particles like ions. Simple diffusion does not require carrier molecules.
- (2) Osmosis: It is diffusion of water across a semipermeable membrane that occurs under the influence of an osmotically active solution.

Mechanism of passive transport: Passive transport can continue to occur if the absorbed solute is immobilised. Cations have a tendency to passively pass from electropositive to electronegative side. While anions can pass from electronegative to electropositive side. There are two modes of passive transport.

- (1) Lipid matrix permeability: Lipid soluble substances pass through the cell membrane according to their solubility and concentration gradient, e.g., triethyl citrate, ethyl alcohol, methane.
- (2) Hydrophilic membrane channels: They are narrow channels formed in the membrane by tunnel proteins. The channels make the membrane semipermeable. Water passes inwardly or outwardly from a cell through these channels according to osmotic gradients. CO_2 and O_2 also diffuse through these channels as per their concentration gradients.

Facilitated transport or Facilitated diffusion: It is passage of substances along the concentration gradient without expenditure of energy that occurs with the help of special permeating substances called permeases. Permeases form pathways for movement of certain substances without involving any expenditure of energy. Facilitated transport occurs in case of some sugars, amino acids and nucleotides.

Active transport : It occurs with the help of energy, usually against concentration gradient. For this, cell membranes possess carriers and gated channels. At times certain substances are transported alongwith the ones requiring active transport. The latter phenomenon called cotransport.

- (1) Carrier particles or Proteins: They are integral protein particles which have affinity for specific solutes. A solute particles combines with a carrier to form carrier solute complex. The latter undergoes conformational change in such a way as to transport the solute to the inner side where it is released into cytoplasm.
- (2) **Gated channels**: The channels are opened by either change in electrical potential or specific substances, *e.g.*, Calcium channels.

Active transport systems are also called pumps. The pumps operate with the help of ATP. $K^+ - H^+$ exchange pump occurs in guard cells. $Na^+ - K^+$ exchange pump operates across many animal membranes.

Active transport of one substance is often accompanied by permeation of other substances. The phenomenon is called secondary active transport. It is of two main types, cotransport (e.g., glucose and some amino acids alongwith inward pushing of excess Na^+) and counter-transport (Ca^{2+} and H^+ movement outwardly as excess Na^+ passes inwardly).

Bulk transport: It is transport of large quantities of micromolecules, macromolecules and food particles through the membrane. It is accompanied by formation of transport or carrier vesicles. The latter are endocytotic and perform bulk transport inwardly. The phenomenon is called **endocytosis**. Endocytosis is of two types, pinocytosis and phagocytosis. Exocytic vesicles perform bulk transport outwardly. It is called exocytosis. Exocytosis performs secretion, excretion and ephagy.

(1) **Pinocytosis**: (Lewis, 1931). It is bulk intake of fluid, ions and molecules through development of small endocytotic vesicles of $100-200 \ nm$ in diameter. ATP, Ca^{2+} , fibrillar protein clathrin and contractile protein actin are required. Fluid-phase pinocytosis is also called cell drinking. After coming in contact with specific substance, the area of plasma membrane having adsorptive sites, invaginates and forms vesicle. The vesicle separates. It is called **pinosome**. Pinosome may burst in cytosol, come in contact with tonoplast and pass its contents into vacuole, form digestive vacuole with lysosome or deliver its contents to Golgi apparatus when it is called **receptosome**.

UNIVERSAL BOOK DEPOT 1960

(2) **Phagocytosis**: (Metchnikoff, 1883). It is cell eating or ingestion of large particles by living cells, e.g., white blood corpuscles (neutrophils, monocytes), Kupffer's cells of liver, reticular cells of spleen, histiocytes of connective tissues, macrophages, Amoeba and some other protists, feeding cells of sponges and coelenterates. Plasma membrane has receptors. As soon as the food particle comes in contact with the receptor site, the edges of the latter evaginate, form a vesicle which pinches off as phagosome.

One or more lysosomes fuse with a phagosome, form digestive vacuole or food vacuole. Digestion occurs inside the vacuole. The digested substances diffuse out, while the residual vacuole passes out, comes in contact with plasma membrane for throwing out its contents through **exocytosis** or ephagy.

Protoplasm (Proto = first, plasm = fluid)

Protoplasm is a complex, granular, elastic, viscous and colourless substance. It is selectively or differentially permeable. It is considered as "Polyphasic colloidal system".

Discoveries

- (1) J. Huxley defined it as "physical basis of life".
- (2) Dujardin (1835) discovered it and called them "sarcode".
- (3) Purkinje (1837) renamed it as "Protoplasm".
- (4) Hugo Von Mohl (1844) gave the significance of it.
- (5) Max Schultz (1861) gave the protoplasmic theory for plants.
- (6) Fischer (1894) and Hardy (1899) showed its colloidal nature.
- (7) Altman (1893) suggested protoplasm as granular.

Table: 3.1-4 Chemically composition

Water	75 - 85%	Carbon	20%
Proteins	10-25%	Oxygen	62%
Lipids	2-3%	Hydrogen	10%
Inorganic materials	1%	Nitrogen	3%

Maximum water content in protoplasm is found in hydrophytes, i.e., 95% where as minimum in seeds, spores (dormant organs) i.e., 10-15%. In animals water is less (about 65%) and proteins are more (about 15%).

Theories regarding nature of protoplasm

Following theories have been put forth regarding the nature of protoplasm.

- (1) **Reticular theory :** Protoplasm possesses a delicate reticular structure. (by Heitzman)
- (2) Granular theory: Protoplasm consists of numerous minute granules (by Altman).
- (3) **Fibrillar theory**: Protoplasm is formed of fibres and these are proteinous nature. (by Flemming)
- (4) **Alveolar theory**: It consists of droplets of alveoli or minute bubbles resembling foams of emulsion (by Butschil).
- (5) Colloidal theory: Protoplasm is a polyphasic colloidal system (by Fisher & Hardy)

- (6) **Sol** \Leftrightarrow **gel theory**: Protoplasm is a colloidal solution consists of dispersion and dispersed phase. It exist in two state i.e., **sol** state (more H_2O) and **gel** state (less H_2O). This theory was proposed by Hyman.
- (7) **Crystallo Colloidal theory :** Protoplasm is crystal, polyphasic, colloidal solution made of various inorganic substances like protein, carbohydrates and fats. This theory was proposed by Kolliker. It is most advanced and accepted theory of protoplasm.

Properties of protoplasm

(1) **Cyclosis movement :** These are shown by protoplasm. These are of two types.

Rotation: In one direction, either clockwise or anticlockwise e.g., Hydrilla, Vallisneria. Found only in eukaryotes.

Circulation : Multidirectional movements around vacuole *e.g.*, *Tradescantia*.

- (2) It shows stimulation or irritability, Sol-gel transformation and Brownian movements.
- (3) It is highly viscous and coagulates at 60° C or above or if treated with concentrated acids or bases.
- (4) It's pH is on acidic side, but different vital activities occur at neutral pH which is considered as 7, injury decreases the pH of the cell (i.e., 5.2-5.5) and if it remains for a long time, the cell dies.

Protoplast : A term coined by Hanstein (1880) include all the living constituents of the protoplasm viz. nucleus, cytoplasm and plasmalemma. It is a simply organized mass of protoplasm bounded by cell membrane with no cell wall.

Cytoplasm

The substance occuring around the nucleus and inside the plasma membrane containing various organelles and inclusions is called cytoplasm.

- (1) The cytoplasm is a semisolid, jelly like material. It consists of an aqueous, structureless ground substance called cytoplasmic matrix or hyaloplasm or cytosol.
- (2) It forms about half of the cell's volume and about 90% of it is water.
- (3) It contains ions, biomolecules, such as sugar, amino acid, nucleotide, tRNA, enzyme, vitamins, etc.
- (4) The cytosol also contains storage products such as glycogen/starch, fats and proteins in colloidal state.
 - (5) It also forms crystallo colloidal system.
- (6) Cytomatrix is differentiated into ectoplasm or plasmagel (outer) and endoplasm or plasmasol (inner).
- (7) Cytomatrix is three dimensional structure appear like a network of fine threads and these threads are called microfilaments (now called actin filaments or microtrabecular lattice) and it is believed to be a part of cytoskeleton. It also contains microtubules and intermediate cytoplasmic filaments.

- (8) Hyaloplasm contains metabolically inactive products or cell inclusions called deutoplast or metaplasts.
- (9) Cytoplasmic organelles are plastid, lysosome, sphaerosome, peroxisome, glyoxysomes, mitochondria, ribosome, centrosome, flagellum or cilia etc.
- (10) The movement of cytoplasm is termed as cyclosis (absent in plant cells).

Mitochondria

Mitochondria (Gk. Mito = thread; chondrion = granule) are semi autonomous having hollow sac like structures present in all eukaryotes except mature RBCs of mammals and sieve tubes of phloem. Mesosomes of prokaryotes (bacteria) is analogous to mitochondrion in eukaryotes.

Mitochondria are also called chondriosome, chondrioplast, plasmosomes, plastosomes and plastochondrione.

Discoveries

- (1) These were first observed in striated muscles (Voluntary) of insects as granules by Kolliker (1850), he called them "sarcosomes".
- (2) Flemming (1882) called them "fila" for thread like structure.
 - (3) Altman (1890) called them "bioplast".
 - (4) C. Benda (1897) gave the term mitochondria.
- (5) F. Meves (1904) observed mitochondria in plant (Nymphaea).
- (6) Michaelis (1898) demonstrated that mitochondria play a significant role in respiration.
- (7) Bensley and Hoerr (1934) isolated mitochondria from liver cells.
 - (8) Seekevitz called them "Power house of the cell".
- (9) Nass and Afzelius (1965) observed first DNA in mitochondria.

Number of mitochondria: Presence of mitochondria depends upon the metabolic activity of the cell. Higher is the metabolic activity, higher is the number e.g., in germinating seeds.

- (1) Minimum number of mitochondria is one in Microasterias, Trypanosoma, Chlorella, Chlamydomonas (green alga) and Micromonas. Maximum numbers are found (upto 500000) in flight muscle cell, (upto 50000) in giant Amoeba called Chaos Chaos. These are 25 in human sperm, 300 400 in kidney cells and 1000 1600 in liver cells.
 - (2) Mitochondria of a cell are collectively called chondriome.

Size of mitochondria: Average size is 0.5– $1.00~\mu m$ and length upto $1-10~\mu$ m. Smallest sized mitochondria in yeast cells $(1~\mu m^3)$ and largest sized are found in oocytes of Rana pipiens and are $20-40~\mu m$.

Ultrastructure: Mitochondria is bounded by two unit membranes separated by perimitochondrial space (6 – 10nm wide). The outer membrane is specially permeable because of presence of integral proteins called porins. The inner membrane is selective permeable. The inner membrane is folded or convoluted to form mitochondrial crests. In animals these are called cristae and in plants these folding are called tubuli or microvili.

The matrix facing face is called 'M' face and face towards perimitochondrial space is called 'C' face. The 'M' face have some small stalked particles called oxysomes or F_1 particle or elementary particle or Rackers particle or Fernandez – Moran Particles (10^4 – 10^5 per mitochondria). Each particle is made up of base, stalk and head and is about 10nm in length.

Oxysomes have ATPase enzyme molecule (Packer, 1967) and therefore, responsible for ATP synthesis. The reaction of ATP formation is endergonic. These elementary particles are also called F_0-F_1 particles. The F_1 particle is made up of five types of subunits namely $\alpha,\beta,\gamma,\delta$ and ε of these α is heaviest and ε is lightest. F_0 particles synthesize all the enzymes required to operate Kreb's cycle.

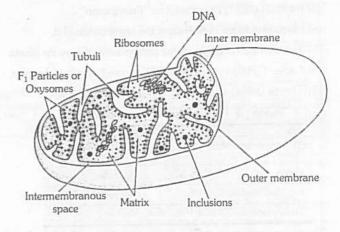

Fig: 3.1-3 Mitochondria of plant cell

Perimitochondrial space

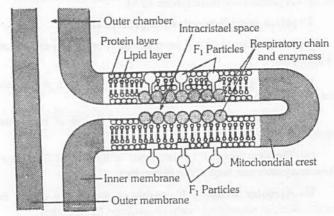

Fig: 3.1-4 Structure of inner membrane of mitochondria

Semi-autonomous nature of mitochondrion: Mitochondria contain all requirements of protein synthesis:

- (1) 70 S ribosomes.
- (2) DNA molecules (rich in G-C ratio) to form mRNA and also replicate.
 - (3) ATP molecules to provide energy.

The mitochondria can form some of the required proteins but for most of proteins, these are dependent upon nuclear DNA and cytoplasmic ribosomes, so the mitochondria are called semiautonomous organelles.

According to endosymbiotic origin of mitochondria by Kirns Altman, mitochondria were intially a free living, aerobic bacteria which during to the process of evolution entered an anaerobic cell and become established as mitochondria. This theory is supported by many similarities which exist between bacteria and mitochondria.

Chemical composition : Cohn gave the chemical composition of mitochondrion :

Proteins = 65 - 70%; Lipids = 25 - 30% (90% phospholipids and 10% cholesterol, Vit. E., etc.); RNA = 5 - 7%. Some amount of DNA 2 - 5%.

The mitochondrial matrix has many catabolic enzymes like cytochrome oxidase and reductases, fatty acid oxidase, transaminase, etc.

Enzymes of Mitochondria

- Outer membrane: Monoamine oxidase, glycerophosphatase, acyltransferase, phospholipase A.
- (2) Inner membrane: Cytochrome b,c_1,c,a , (cyt.b, cyt.c₁, cyt.c, cyt.a, cyt.a₃) NADH, dehydrogenase, succinate dehydrogenase, ubiquinone, flavoprotein, ATPase.
- (3) Perimitochondrial space: Adenylate kinase, nucleoside diphosphokinase.
- (4) Inner matrix: Pyruvate dehydrogenase, citrate synthase, aconitase, isocitrate dehydrogenase, fumarase, α Ketoglutarate dehydrogenase, malate dehydrogenase.
- **Origin:** Mitochondria are self-duplicating organelles due to presence of DNA molecules so new mitochondria are always formed by growth and division of pre-existing mitochondria by binary fission.

Functions

- (1) Mitochondria are called power house or storage batteries or ATP mills formation of ATP is called oxidative phosphorylation.
- (2) Intermediate products of cell respiration are used in the formation of steroids, cytochromes, chlorophyll, etc.
 - (3) These are also seat of some amino acid biosynthesis.
- (4) Mitochondria also regulate the calcium ion concentration inside the cell.

- (5) Site of thermiogenesis.
- (6) Yolk nucleus (a mitochondrial cloud and golgi bodies) controls vitellogenesis.
- (7) Mitochondria of spermatid form nebenkern (middle piece) of sperm during spermiogenesis.
 - (8) Mitochondria release energy during respiration.
 - (9) Mitochondria contain electron transport system.

Plastids

Plastids are semiautonomous organelles having DNA, RNA, Ribosomes and double membrane envelope. These are largest cell organelles in plant cell.

History

- (1) Haeckel (1865) discovered plastid, but the term was first time used by Schimper (1883).
- (2) A well organised system of grana and stroma in plastid of normal barley plant was reported by de Von Wettstein.
 - (3) Park and Biggins (1964) gave the concept of quantasomes.
- (4) The term chlorophyll was given by Pelletier and Caventou, and structural details were given by Willstatter and Stall.
 - (5) The term thylakoid was given by Menke (1962).
 - (6) Fine structure was given by Mayer.
- (7) Ris and Plaut (1962) reported DNA in chloroplast and was called plastidome.

Types of plastids: According to Schimper, Plastids are of 3 types: Leucoplasts, Chromoplasts and Chloroplasts.

Leucoplasts: They are colourless plastids which generally occur near the nucleus in nongreen cells and possess internal lamellae. Grana and photosynthetic pigments are absent. They mainly store food materials and occur in the cells not exposed to sunlight *e.g.*, seeds, underground stems, roots, tubers, rhizomes etc. These are of three types.

- (1) **Amyloplast**: Synthesize and store starch grains. *e.g.*, potato tubers, wheat and rice grains.
- (2) Elaioplast (Lipidoplast, Oleoplast): They store lipids and oils e.g., castor endosperm, tube rose, etc.
- (3) **Aleuroplast (Proteinoplast)**: Store proteins *e.g.*, aleurone cells of maize grains.

Chromoplasts: Coloured plastids other than green are known as chromoplasts. These are present in petals and fruits. These also carry on photosynthesis. These may arise from the chloroplasts due to replacement of chlorophyll by other pigments.

Green tomatoes and chillies turn red on ripening because of replacement of chlorophyll molecule in chloroplasts by the red pigment lycopene in tomato and capsanthin in chillies. Thus, chloroplasts are changed into chromatoplast.

All colours (except green) are produced by flavins, flavenoids and cyanin. Cyanin pigment is of two types one is anthocyanin (blue) and another is erythrocyanin (red). Anthocyanin are water soluble pigments and found in cell sap of vacoule.

Chloroplast: Discovered by Sachs and named by Schimper. They are greenish plastids which possess photosynthetic pigments. Chloroplast are also known as factory for synthesis of sugars.

Number: It is variable. Number of chloroplast is 1 in Spirogyra indica, 2 in Zygnema, 16 in S.rectospora, upto 100 in mesophyll cells. The minimum number of one chloroplast per cell is found in *Ulothrix* and species of *Chlamydomonas*.

Shape: They have various shapes

Shape	Example
Cup shaped	Chlamydomonas sp.
Stellate shaped	Zygnema.
Collar or girdle shaped	Ulothrix
Spiral or ribbon shaped	Spirogyra
Reticulate/net like	Oedogonium
Discoid	Voucheria
Spherical	Chlorella
Biconvex/ovoid	Angiosperm

Size: It ranges from $3-10\,\mu m$ (average $5\,\mu m$) in diameter. The discoid chloroplast of higher plants are $4-10\,\mu m$ in length and $2-4\,\mu$ m in breadth. Chloroplast of *Spirogyra* may reach a length of $1\,mm$. Sciophytes (Shade plant) have larger chloroplast.

Chemical composition: Proteins 50-60%; Lipids 25-30%; Chlorophyll -5-10 %; Carotenoids (carotenes and xanthophylls) 1-2%; DNA -0.5%, RNA 2-3%; Vitamins K and E; Quinines, Mg, Fe, Co, Mn, P, etc. in traces.

Ultrastructure: It is double membrane structure. Both membranes are smooth. The inner membrane is less permeable than outer but rich in proteins especially carrier proteins. Each membrane is 90-100 Å thick. The inter-membrane space is called the periplastidial space. Inner to membranes, matrix is present, which is divided into two parts.

(1) **Grana**: Inner plastidial membrane of the chloroplast is invaginated to form a series of parallel membranous sheets, called lamellae, which form a number of oval – shaped closed sacs, called thylakoids. Thylakoids are structural and functional elements of chloroplasts.

Along the inner side of thylakoid membrane, there are number of small rounded para-crystalline bodies, called quantasomes (a quantasome is the photosynthetic unit).

Park and Biggins (1964) discovered quantasomes. Each quantasome contains about 230 chlorophyll molecules (160 chl. 'a' and 70 chl. 'b') and 50 carotenoid molecules.

In eukaryotic plant cells, a number of thylakoids are superimposed like a pile of coins to form a granum. The number of thylakoids in a granum ranges from 10-100 (average number is 20-50). Adjacent grana are interconnected by branched tubules, called stromal lamellae or Fret-channel or Fret membrane's.

(2) **Stroma**: It is transparent, proteinaceous and watery substance. Dark reaction of photosynthesis occurs in this portion. Stroma is almost filled with "Rubisco" (about 15% of total enzyme, protein) enzyme CO_2 is accepted by this enzyme. CO_2 assimilation results in carbohydrate formation. It has 20-60 copies of naked circular double stranded DNA.

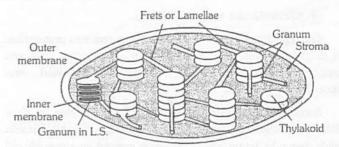

Fig: 3.1-5 A chloroplast in section (diagrammatic)

Pigments of chloroplast

Chlorophyll a: $C_{55} H_{72} O_5 N_4 Mg$ (with methyl group)

Chlorophyll b: $C_{55} H_{70}O_6N_4Mg$ (with aldehyde group)

Chlorophyll c: C₃₅H₃₂O₅ N₄Mg

Chlorophyll d: C₅₄ H₇₀ O₆N₄Mg

Bacteriochlorophyll $(C_{55}H_{74}O_6N_4Mg)$ or chlorobium chlorophyll present in photosynthetic bacteria. These pigment are red in acidic and blue in alkaline medium.

Carotenoids : These are hydrocarbons, soluble in organic solvents. These are of two types :

- (1) **Carotenes** : $C_{40}H_{56}$ derivatives of vitamin A. Carrot coloured α, β, γ carotene, lycopene, etc. β carotene most common.
- (2) **Xanthophyll :** $C_{40}H_{56}O_2$, yellowish in colour, fucoxanthin, violaxanthin. Molar ratio of carotene and xanthophyll in young leaves is 2:1.

Origin of chloroplast: Plastids, like the mitochondria, are self duplicating organelles. These develop from colourless precursors, called proplastids. They are believed to be evolved from endosymbiont origination.

Functions

- (1) It is the site of photosynthesis, (light and dark reaction).
- (2) Photolysis of water, reduction of NADP to NADPH₂ take place in granum.
- (3) Photophosphorylation through cytochrome b_6 f, plastocyanine and plastoquinone etc.
 - (4) They store starch or factory of synthesis of sugars.
 - (5) Chloroplast store fat in the form of plastoglobuli.
- (6) They maintain the percentage of CO_2 and O_2 in atmosphere.

Endoplasmic reticulum (ER)

It is well developed electron microscopic network of interconnected cisternae, tubules and vesicles present throughout the cytoplasm, especially in the endoplasm.

Discovery: Garnier (1897) was first to observe the ergastoplasm in a cell. The ER was first noted by Porter, Claude, and Fullman in 1945 as a network. It was named by Porter in 1953.

Occurrence: The ER is present in almost all eukaryotic cells. A few cells such as ova, embryonic cells, and mature RBCs, however, lack ER. It is also absent in prokaryotic cell. In rapidly dividing cells endoplasmic reticulum is poorly developed.

Ultrastructure : The ER is made up of three components. All the three structures are bound by a single unit membrane.

- (1) Cisternae: These are flattened, unbranched, sac like structures. They lie in stacks (piles) parallel to one another. They bear ribosomes. They contain glycoproteins named ribophorin-I and ribophorin-II that bind the ribosomes. Found in protein forming cells.
- (2) **Vesicles**: These are oval or rounded, vacuole like elements, scattered in cytoplasm. These are also studded with ribosomes.
- (3) Tubules: Wider, tubular, branched elements mainly present near the cell membrane. They are free from ribosomes. These are more in lipid forming cells.

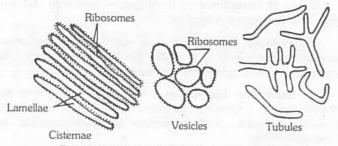

Fig: 3.1-6 Elements of Endoplasmic Reticulum

Types of ER: Depending upon the presence of ribosomes, the ER has been categorised into two types:

- (1) A smooth or Agranular endoplasmic reticulum (SER): It consists mainly of tubules and vesicles. It has no ribosomes associated to it. It is well developed in the muscle cells, adipose tissue cells, interstitial cells, glycogen storing liver cells, etc. and the cells that synthesize and secrete steroids. SER also takes part in synthesis of vitamins, carbohydrates and detoxification. It gives rise to sphaerosomes. It occurs in cells engaged in producing large quantity of lipids.
- (2) Rough or Granular endoplasmic reticulum (RER): It mainly consists of cisternae. It has ribosomes attached on its cytoplasmic surface. It is abundant in cells engaged in production and excertion of proteins, e.g., plasma cells, goblets cells, pancreatic acinus cells and certain liver cells. The RER is more stable than SER. The RER is basophilic due to the presence of ribosomes. Ribosomes are attached to ER through hydrophobic interaction.

A third type annulate endoplasmic reticulum was discovered by Mecullo in 1972. It may be smooth or rough having pores like nuclear envelop.

Origin: RER is formed from nuclear membrane while SER is formed from RER by loss of ribosomes. Rough vesicles originate only from RER after homogenisation of cell. RER breaks in small fragments (Vesicles) and it is called microsome (This is not a cell organelle).

Functions

- (1) Synthesis and secretion of specific proteins via golgi bodies.
- (2) Provides surface for synthesis of cholesterol, steroid, ascorbic acid, visual pigments and hormones *e.g.*, testosterone and estrogen.
- (3) It helps in glycogenolysis in the liver cells and brings about detoxification (SER).
- (4) ER is a component of cytoskeleton (Spread as a net) of cell and provides mechanical support and shape to the cell.
- (5) ER acts as segregation apparatus and divides the cytoplasm into chambers. Compartmentalisation is most necessary for cellular life.
- (6) It participates in the formation of cell-plate during cytokinesis in the plant cells by the formation of phragmoplasts.
 - (7) ER forms 30-60% part of total membranous system.
 - (8) It gives rise to vacoules.
- (9) Sarcoplasmic reticulum: It is a modified SER striated muscle fibres (Veratti, 1902) which forms a network of interconnected tubules in the sarcoplasm. It helps in conduction of motor nerve impulses throughout the muscle fibre and in the removal of lactic acid so prevents muscle fatigue. It is called "Sarcoplasmic reticulum" in muscle and "Nissl'sgranules" in nerve cells, mylloid body in retinal cells.

Golgi complex

Golgi complex is made up of various membranous system e.g., cisternae, vesicles and vacuoles. These are also called golgi bodies, golgisomes, lipochondrion, dictyosomes, Dalton complex, idiosomes or Baker's body and "traffic police" of the cell.

Discovery: First observed by George (1867) but it's morphological details were given by Camillo Golgi (1898), in nerve cells of barn owl and cat.

Occurence: It is present in all eukaryotic cells. *In plants*, these are scattered irregularly in the cytoplasm and called as "dictyosomes". These are absent in bacteria and blue green algae, RBCs, spermatozoa of bryophytes and pteridophytes, and sieve tube cells of phloem of angiosperm. The number of Golgi bodies/dictyosomes is generally 9 – 10 in a plant cell but is very high in cells engaged in secretory activity (e.g., root cap cells). The number of golgi body is increased during cell division. Golgi body surrounded by a zone of protoplasm which is devoid of cell organelles called zone of exclusion (Morre, 1977).

Structure: Under transmission electron microscope the structure of golgibodies was study by Dalton and Felix (1954), golgi body is made of 4 parts.

- (1) Cisternae: Golgi apparatus is made up of stack of flat sac like structure called cisternae. The margins of each cisterna are gently curved so that the entire golgi body takes on a cup like appearance. The golgi body has a definite polarity. The cisternae at the convex end of the dictyosome comprises forming face (F. face) or cis face. While the cisternae at the concave end comprises the maturing face (M. face) or trans face. The forming face is located next to either the nucleus or endoplasmic reticulum. The maturing face is usually directed towards the plasma membranes. It is the functional unit of golgi body.
- (2) Tubules: These arise due to fenestration of cisternae and it forms a complex network.
- (3) Secretory vesicles: These are small sized components each about 40 Å in diameter present along convex surface of edges of cisternae. These are smooth and coated type of vesicles.
- (4) Golgian vacuoles: They are expanded part of the cisternae which have become modified to form vacuoles. The vacuoles develop from the concave or maturing face. Golgian vacuoles contain amorphous or granular substance. Some of the golgian vacuoles function as lysosomes.

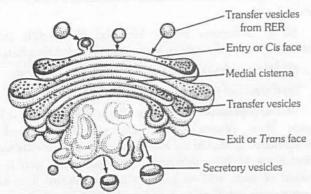

Fig: 3.1-7 Structure of Golgi complex

Origin: Most accepted view is that golgi body originates from RER-that has lost its ribosomes from this RER arise transport vesicles that contain Golgi membrane and fuse with the saccule on the forming face of Golgi apparatus. This is why this face is called the forming face.

Functions

- (1) The main function of golgi body is secretion, so it is large sized among the secretory cells.
- (2) Glycosidation of lipids i.e., addition of oligosaccharides to produce glycolipids.
- (3) Glycosylation of proteins i.e., addition of carbohydrate to produce glycoproteins.
 - (4) Formation of primary lysosomes.
- (5) Golgi body forms the cell plate. During cell division by secreting hemicellulose formation of enzyme and hormones (Thyroxine) etc.
- (6) In oocytes of animal, golgi apparatus functions as the centre around which yolk is deposited i.e., vitellogenesis.
- (7) Membrane of the vesicles produced by golgi apparatus join in the region of cytokinesis to produce new plasmalemma.
 - (8) It is also called export house of cell.

- (9) Golgi body contains phospholipids, proteins, enzymes and vitamin.
- (10) The golgi complex gives rise to the acrosome in an animal sperm.

Lysosomes

Lysosomes are electron microscopic, vesicular structures of the cytoplasm, bounded by a single membrane (lipoproteinous) which are involved in intracellular digestive activities, contains hydrolytic enzymes, so called lysosomes.

Discovery

- (i) These were first discovered by a Belgian biochemist, Christian de Duve (1955) in the liver cells and were earlier named pericanalicular dense bodies.
- (ii) Term Lysosome was given by Novikoff under the study of electron microscope.
- (iii) Matile (1964) was first to demonstrate their presence in plants, particularly in the fungus *Neurospora*. Polymorphism in lysosomes were described by De Robertis et. al (1971).

Occurrence: These are absent from the prokaryotes but are present in all eukaryotic animal cells except mammalian RBCs. They have been recorded in fungi, Euglena, cotton and pea seeds.

Shape: These are generally spherical in shape but are irregular in plant root tip cells.

Size: Size range is $0.2\text{-}0.8~\mu\text{m}$ while size is $0.5~\mu\text{m}$ (500 nm).

Types of Lysosomes : On the basis of their contents, four types of lysosomes are recognised.

- (1) Primary Lysosomes: A newly formed lysosome contains enzymes only. It is called the primary lysosomes. Its enzymes are probably in an inactive state.
- (2) Secondary Lysosomes: When some material to be digested enters a primary lysosome, the latter is named the secondary lysosome, or phagolysosome or digestive vacuole, or heterophagosome.
- (3) **Tertiary lysosomes/Residual bodies**: A secondary lysosome containing indigestible matter is known as the *residual bodies* or *tertiary lysosome*. The latter meets the cell by *exocytosis* (*ephagy*).
- (4) Autophagosomes/Autolysosomes: A cell may digest its own organelles, such as mitochondria, ER. This process is called autophagy. These are formed of primary lysosomes. The acid hydrolases of lysosomes digest the organelles thus, it is called autophagosome. The lysosome are sometimes called disposal units/suicidal bags. Sometime they get burst and causes the destruction of cell or tissue.

Chemical composition: Matrix of primary lysosome is formed of hydrolases, which is involved in hydrolysis or polymeric compounds, that operate in acidic medium at *pH* 5, so called acid hydrolases. Upto now 50 types of enzyme have been reported. These are as:

Proteases (cathepsin and collagenase), Nucleases (DNAse and RNAse), Glycosidases (β -galactosidase, β -glucoronidase), Phosphatases (ATPase, acid phosphatase /marker enzyme).

Functions

- (1) Lysosomes of sperms provide enzyme for breaking limiting membrane of egg e.g., hyaluronidase enzyme.
- (2) Lysosomes functions as trigger of cell division or initiate cell division by digesting repressor molecules.
- (3) Nucleases (DNAse) of lysosomes may cause gene mutations which may cause disease like leukemia or blood cancer (partial deletion of 21st chromosome).
- (4) Sometimes residual bodies accumulate inside the cells leading to storage diseases *e.g.*, a glycogen storage disease called Pompe's disease, polynephritis Hurler's disease (deformed bones due to accumulation of mucopolysaccharides).
 - (5) Lysosomes also engulf the carcinogens.

Ribosome

The ribosomes are smallest known electron microscopic without membrane, ribonucleo-protein particles attached either on RER or floating freely in the cytoplasm and are the sites of protein synthesis.

Discovery: In 1943 Claude observed some basophilic bodies and named them as microsome. Palade (1955) coined the term ribosome (form animal cell). Ribosomes in nucleoplasm were observed by Tsao and Sato (1959). First isolated by Tissieres and Watson (1958) from E. coli. Ribosomes found in groups are termed as polyribosomes or ergosomes (Rich and Warner 1963 observed first time polyribosomes).

Occurrence: In prokaryotes ribosomes are found only in free form in the cytoplasm. While in the eukaryotes the ribosomes are found in two forms in the cytoplasm, free form and bind form (bound on RER and outer nuclear membrane). These are also reported inside some cell organelles like mitochondria and plastids respectively called mitoribosomes and plastidoribosomes.

Types of ribosomes

- (1) **70S ribosomes :** Found in prokaryotes, mitochondria and plastid of eukaryotes.
 - (2) 80S ribosomes: Found in cytoplasm of eukaryotes.
- (3) **77S, 60S and 55S ribosomes**: Levine and Goodenough (1874) observed 77S ribosomes in fungal mitochondria 60S ribosomes in animal mitochondria and 55S in mammalian mitochondria.

Structure: Each ribosome is formed of two unequal subunits, which join only at the time of protein synthesis. In 70S and 80S ribosomes, 50S and 30S, 60S and 40S are larger and smaller subunits respectively. Larger subunits is dome shaped and attached to ER by glycoproteins called "ribophorins".

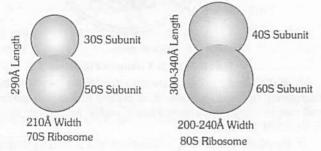

Fig: 3.1-8 Structure of 70S and 80S ribosome

Smaller subunit is oval shaped and fits as a cap on flat side of larger subunit. Ribosomes are attached to ER through hydrophobic interactions.

Chemical composition : Ribosomes are chemically composed of rRNA and proteins Ribonucleo-Protein (RNP). 70S ribosomes has 60-65% rRNA and 35-40% proteins (ratio is 2:1). rRNAs are of three types: 23S type and 5S type rRNAs in 50S and 16S type rRNA in 30S sub-units.

80S ribosome has 45% rRNA and 55% proteins (ratio is about 1:1). r-RNA are of four types : 28S, 5S and 5.8S types of rRNAs in 60S and 18S type rRNA in 40S sub-units.

A 1×10^{-3} (0.001 M) molar concentration of Mg^{++} is needed for the structural cohesion of ribosomes *i.e.*, for holding the two subunits together. If this concentration is increased by ten folds, two ribosomes unite to form a *dimer*. By decreasing the Mg^{++} conc. to normal, the dimer breaks into monomers (single ribosomes).

Biogenesis of ribosome

- (1) In eukaryotes the ribosomal RNAs like 18S, 5.8S and 28S are synthesized by nucleolus and 5S RNA out of the nucleus.
- (2) In prokaryotes both rRNA and its protein are synthesized as well as assembled by cytoplasm.

Polyribosomes or Polysomes : When many ribosomes (generally 6-8) are attached at some mRNA strand. It is called polysome. The distance between adjacent ribosomes is of 90 nucleotides. These are functional unit of protein synthesis.

Functions

- (1) Ribosomes are also called protein factories of the cell or work branch of proteins.
- (2) Free ribosomes synthesize structural proteins and bounded ribosomes synthesize proteins for transport.
 - (3) Ribosomes are essential for protein synthesis.
 - (4) Help in the process of photosynthesis.
- (5) Enzyme peptidyl transferase occurs in large subunit of ribosome which helps in protein synthesis.
- (6) Newly formed polypeptide is protected from degradation by cytoplasmic enzymes in large sub-unit of ribosomes before releasing it into RER lumen.

Microbodies

(1) Sphaerosomes

Discovery: These were first observed by Hanstein (1880) but discovered by Perner (1953). Term sphaerosomes was given by Dangeard.

Occurrence: Sphaerosomes, arise from the E.R. These are found in all the plant cells which involves in the synthesis and storage of lipids *i.e.*, endosperm and cotyledon of oil seeds.

Shape, size and structure : These are spherical or oval in shape about $0.5-2.5~\mu m$ in diameter. They contain hydrolytic enzymes like protease, ribonuclease, phosphatase, esterase etc. They are bounded by a single unit membrane.

Function: The main function of sphaerosomes is to help in lipid metabolism. These are also known as plant lysosomes.

(2) Peroxisomes (Uricosomes)

Discovery: These were discovered by Tolbert (1969). De Duve (1965) isolated certain sac like organelles from various types of animals and plants. These were called peroxisomes because these contain peroxide producing enzymes (oxidases) and peroxide destroying enzymes (catalases).

Occurrence: These are found in photosynthetic cells of plants. In animals peroxisomes are found in vertebrates (cells of liver, kidney), brain, small intestine, testis and adrenal cortex), invertebrates and protozoans *e.g.*, Paramecium.

Shape, size and structure : These are spherical in shape, about $1.5~\mu m$ in size. They are bounded by a single unit membrane.

Their membrane is permeable to amino acids, uric acids, etc. They contain four enzymes of H_2O_2 metabolism. The enzymes urate oxidase, d-amino oxidase, α -hydroxy acid oxidase produce H_2O_2 whereas the catalases plays a significant protective role by degrading H_2O_2 because H_2O_2 is toxic for cells.

Function : These are involved in the formation and degrading of H_2O_2 . Plant peroxisomes are also involved in photorespiration.

(3) Glyoxysomes

Discovery: These were discovered by Beevers in 1961 and Briedenbach in 1967.

Occurrence: These are found in fungi, some protists and germinating fatty seeds where insoluble lipid food reserves must be turned into soluble sugars. Absent in animal cell.

Shape, size and structure: These are spherical in shape, about $0.5\text{-}1\mu\text{m}$ in size, they contain enzymes of metabolism of glycolic acid via glyoxylate cycle and bounded by a unit membrane. These also contain enzymes for β -oxidation of fatty acids. Produced acetyl CoA. The latter is metabolised in glyoxlate cycle to produce carbohydrates.

Functions: The main function of glyoxysomes is conversion of fats into carbohydrates.

(4) Lomasomes: These are sac like structures found between cell wall and plasmalemma in the haustoria of fungal hyphae. These were discovered by Moore and McAlear (1961). Webster called them border bodies.

Centrosome

Discovery: Centrosome was first discovered by Van Benden (1887). Term and structure was given by T. Boweri.

Occurrence: It is found in all the animal cell except mature mammalian RBC's. It is also found in most of protists and motile plant cells like antherozoids of ferns, zoospores of algae and motile algal forms e.g., Chlamydomonas but is absent in prokaryotes, fungi, gymnosperms and angiosperms.

Structure: Centrosome is without unit membrane structure. It is formed of two darkly stained granules called centrioles, which are collectively called diplosome. These centrioles are surrounded by a transparent cytoplasmic area called centrosphere or Kinetoplasm. Centriole and centrosphere are collectively called centrosome. Each centriole is a microtubular structure and is formed of microtubules arranged in 9+0 manner (all the 9 microtubules are peripheral in position). Inside the microtubules, there is an intra-centriolar or cart-wheel structure which is formed of a central hub (about 25Å in diameter) and 9 radial spokes or radial fibres.

Chemical composition: Centrosome is lipoproteinaceous structure. The microtubules of centriole are composed of protein tubulin and some lipids. They are rich in ATPase enzyme.

Origin: The daughter centriole is formed from the preexisting centriole in G_2 of interphase so called self-replicating organelle.

Functions

- The centrioles help organising the spindle fibres and astral rays during cell division.
- (2) They provide basal bodies which give rise to cilia and flagella.

Cilia and Flagella

Discovery: Flagellum presence was first reported by Englemann (1868). Jansen (1887) was first scientist to report the structure of sperm flagellum.

Definition: Cilia and flagella are microscopic, hair or threadlike motile structures present extra-cellularly but originate intracellularly from the basal body.

Occurrence : Cilia are found in all the ciliate protozoans *e.g.*, Paramecium, *Vorticella* etc.

Flagella are found in all the flagellate protozoans e.g., Euglena, Trichonympha etc.

Structure: Both cilia flagella are structurally similar and possess similar parts-basal body, rootlets, basal plate and shaft.

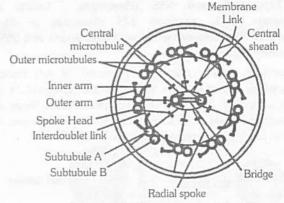

Fig: 3.1-9 T.S. Cilium or Flagellum

- (1) Basal body: These are also termed as blepharoplast (kinetosome) or basal granule. It is present below the plasma membrane in cytoplasm. The structure is similar to centriole made of 9 triplets of microtubules.
- (2) Rootlets: Made of microfilament and providing support to the basal body.

UNIVERSAL BOOK DEPOT 1960

- (3) Basal plate: Central fibril develop in this area. It is highly dense and lie above plasma-membrane. The basal body and the shaft at the level of plasma membrane.
- (4) **Shaft**: It is the hair like projecting part of cilia and flagella which remains outside the cytoplasm. It has 9 doublet of microtubules in radial symmetry. These are called axonema. Each axonema has 11 fibrils, 9 in the periphery and 2 in the centre. The arrangement is called 9+2 pattern.

Chemical composition : Chemically, the central tubules are formed of dynein protein while the peripheral microtubules are formed of tubulin protein.

Type of flagella: There are two types of flagella.

- Tinsel type: In this, flagellum has lateral hair-like processes, called flimmers or mastigonemes.
 - (2) Whiplash type: In this, flagellum has no flimmers.

Functions

- They help in locomotion, respiration, cleaning, circulation, feeding, etc.
- (2) Being protoplasmic structure they can function as sensory organs.
- (3) They show sensitivity to changes in light, temperature and contact.

Table: 3.1-5 Difference between cilia and flagella

Cilia	Flagella
More in number (may be upto 14,000 per cell).	Less in number (1-8).
Small sized (5-10 µm).	Large sized (upto 100-200 µm)
Generally distributed on whole body.	Generally located at anterior end of body.
Beat in either metachronous or synchronous coordination.	Beat independently.
Sweeping or rowing motion.	Undulatory motion.
Locomotion, feeding, circulation, etc.	Only locomotion.

Cytoskeleton

In eukaryotic cell, a framework of fibrous protein elements became necessary to support the extensive system of membranes. These elements collectively form cytoskeleton of the cell. There are of three types.

(1) **Microtubules**: These were first discovered by De Robertis and Franchi (1953) in the axons of medullated nerve fibres and were named neurotubules. The term was coined by Slautterback (1963).

Position: The microtubules are electron-microscopic structures found only in the eukaryotic cellular structures like cilia, flagella, centriole, basal-body, astral fibres, spindle fibres.

Structure: A microtubule is a hollow cylindrical structure of about $250\,\text{\AA}$ in diameter with about $150\,\text{\AA}$ luman. Its wall is about 50\AA thick. Its walls is formed of 13 parallel, proto-tubules.

Chemical composition: These are mainly formed of tubulin protein. A tubulin protein is formed of 2 sub-units: α – tubulin molecule and β – tubulin molecule which are alternatively in a helical manner.

Functions

- These form a part of cytoskeleton and help in cell-shape and mechanical support.
- (2) The microtubules of cilia and flagella help in locomotion and feeding.
- (3) The microtubules of asters and spindle fibres of the mitotic apparatus help in the movement of chromosomes towards the opposite poles in cell-division.

(2) Microfilament

Discovery: These were discovered by Paleviz et. al. (1974).

Position : These are electron-microscopic, long, narrow, cylindrical, non-contractile and proteins structures found only in the eukaryotic cytoplasm. These are present in the microvilli, muscle fibres (called myofilaments) etc. But these are absent in prokaryotes.

Structure: Each microfilament is a solid filament of 50-60 Å diameter and is formed of a helical series of globular protein molecules. These are generally grouped to form bundles.

Chemical composition : These are mainly formed of actin-protein (contractile).

Functions

- (1) The microfilaments forms a part of cytoskeleton and change the cell shape during development, motility and division.
- (2) The microfilaments bring about directed movements of particles and organelles along them in the cell.
- (3) The microfilaments also produce streaming movements of cytoplasm.
- (4) The microfilaments are responsible for the movement of cell membrane during endocytosis and exocytosis.

(3) Intermediate filaments

Location: They are supportive elements in the cytoplasm of the eukaryotic cells. They are missing in mammalian RBCs.

Structure: The IFs are somewhat larger than the microfilaments and are about 10 nm thick. They are solid, unbranched and composed of nonmotile structural proteins, such as keratin, desmine, vimentin.

Functions

- They form a part of cytoskeleton that supports the fluid cytosol and maintains the shape of the cell.
 - (2) They provided strength to the axons.
 - (3) They keep nucleus and other organelles in place.

Nucleus

The nucleus also called director of the cell. It is the most important part of the cell which directs and controls all the cellular function.

UNIVERSAL BOOK DEPOT 1960

502 Cell: The Unit of Life

Discovery: The nucleus was first observed by *Robert Brown* (1831), in orchid root cells. Nucleus plays determinative (in heredity) role in cell and organism, that was experimentally demonstrated by *Hammerling* (1934) in surgical experiments with green marine unicelled algae *Acetabularia*.

Occurence: A true nucleus with definite nuclear membrane and linear chromosome, is present in all the eukaryotes except mature mammalian RBCs, sieve tube cell of phloem, tracheids and vessels of xylem. The prokaryotes have an incipient nucleus, called nucleoid or prokaryon or genophore or false nucleus.

Number: Usually there is a single nucleus per cell i.e., mononucleate condition, e.g., Acetabularia.

- Anucleate (without nucleus): RBCs of mammals, phloem sieve tube, trachids and vessels of xylam.
 - (2) Binucleate: e.g., Ciliate, Protozoans like Paramecium.
- (3) **Polynucleate**: e.g., fungal hyphae of *Rhizopus*, *Vaucheria*. Polynucleate condition may be because of fusion of a number of cells. i.e., syncytium, coconut endosperm or by free nuclear divisions without cytokinesis i.e., coenocyte.

Shape: It varies widely, generally spherical *e.g.*, cuboidal germ cells, oval *e.g.*, columnar cells of intestine, bean shaped in paramecium, horse-shoe shaped in Vorticella, bilobed, *e.g.*, WBCs (acidophils), 3 lobed *e.g.*, basophil, multilobed *e.g.*, neutrophils, long and beaded form (moniliform) *e.g.*, stentor and branched in silk spinning cells of platy phalyx insect larva.

Size: The size of nucleus is variable i.e., $5-30\mu$. In metabolically active cells size of the nucleus is larger than metabolically inactive cells.

Chemical composition

Proteins = 80%, DNA = 12%, RNA= 5%, Lipids = 3%

Enzymes like polymerases are abundantly present and help in synthesis of DNA and RNA.

Ultrastructure: The nucleus is composed of following structure.

 Nuclear membrane: It is also called nuclear envelope or nucleolemma or karyotheca, was first discovered by Erclab (1845).

Structure: It is a bilayered envelope. Each membrane is about 60-90Å thick lipoproteinous and trilaminar. Outer membrane, called ectokaryotheca (with ribosome) and inner membrane is called endokaryotheca (without ribosome). Two membranes are separated by a fluid-filled intermembranous perinuclear space (about 100-300Å).

Nuclear membrane is porous and has 1,000-10,000 octagonal nuclear pores. Each nuclear pore is about 400-1,000 Å in diameter (average size is 800 Å). Callan and Tamlin (1950) first to observe nuclear pore in nuclear membrane. The nuclear pores are enclosed by circular structure are called annuli. The pore and annuli together are called pore complex or pore basket.

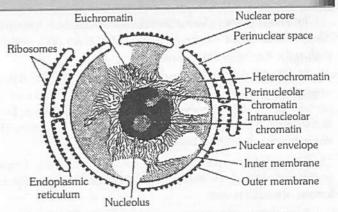

Fig: 3.1-10 Electron microscopic structure of nucleus

Origin: It is formed by the fusion of ER elements during the telophase of cell division.

Functions

- (i) It regulates the nucleo-cytoplasmic interactions.
- (ii) It allows the passage of inorganic ions, small organic molecules, ribosomal subunits, RNAs and proteins through nuclear pores.
 - (iii) It maintains the shape of the nucleus.
- (2) The nucleolus (Little nucleus plasmosome): It was first observed by Fontana (1781) in the skin cells of an eel. Bowman (1840) coined term 'nucleolus'. Wagner (1840) gave its light microscopic structure.

Position: It is generally associated with nucleolar organizer region (NOR) of the nucleolar chromosomes. It is absent in muscle fibres, RBC, yeast, sperm and prokaryotes.

Number: Generally, a diploid cell is with two nucleoli but there are five nucleoli in somatic cell of man and about 1000 nucleoli in the oocytes of Xenopus.

Structure : (De Robertis et.al 1971). A nucleolus is distinguishable into following regions:-

- (1) **Chromatin**: The nucleolus is surrounded by perinucleolar chromatin.
- (2) Pars fibrosa : Fibrils of 80 100 Å size form a part of the nucleolus.
- (3) **Pars granulosa :** Granules of 150 200 Å diameter constitute the granular part of the nucleolus. Ribosome formation takes place in this part so it is called assembly line of ribosome.
- (4) Pars amorpha: The granules and the fibrils lie dispersed in an amorphous proteinaceous matrix. Nucleolus is stained by "pyronine". It is not bounded by any limiting membrane.

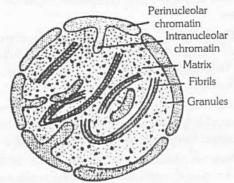

Fig: 3.1-11 Ultrastructure of a Nucleolus

Chemical composition: Nucleolus is mainly formed of RNA and non histone acidic proteins. It is a store house of rRNA.

Origin: A nucleolus is formed at specific sites, called the nucleolar organizers, present on certain chromosomes region (NOR).

Functions

- (i) It is seat of biogenesis of rRNA and also stores rRNA.
- (ii) It plays important role in spindle formation during cell division
- (iii) It receives the ribosomal proteins from the cytoplasm, combines the rRNAs and ribosomal proteins to form ribosomal subunits. So it is also called ribosome producing machine or factory.
- (3) **Nucleoplasm :** It is also called karyolymph. It is transparent, homogenous, semifluid, colloidal, ground substance present inside the nuclear membrane. It contains Nucleic acid (DNA and RNA), Proteins (Basic proteins and acidic protein), Enzyme (DNA and RNA polymerase, NAD synthetase etc.), Minerals (K, Na, Ca, Mg etc.) and Ribonucleoproteins.

The nucleoplasm helps in maintaining the shape of nucleus formation of spindle protein of NAD, ATP, DNA, RNAs and ribosomal subunits. Plasmosome and karyosome combindly called "amphinucleoli".

- (4) **Chromatin fibres** /**Nuclear chromatin :** The nucleoplasm contains many thread like, coiled and much elongated structures which take readily the basic stains such as "basic fuchsine". These thread like structures are known as chromatin fibre. They are uniformly distributed in the nucleoplasm. They are observed only in the "interphase stage".
- (5) **Nuclear matrix**: It is network of proteinaceous fibrils. It is outer thicker part is called fibrous lamina (Haris and James, 1952).

Chromosome (Gr. chroma = colour soma = body)

Chromosome were discovered by Hofmeister (1848) in filament of pollen mother cells of tradescantia (Rhoeodiscolour) studied by strasburger (1875) and given the present name by Waldeyer (1888).

During interphase, chromatin threads are present in the form of a network called chromatin reticulum. At the time of cell division, these thread like structures of chromatin become visible as independent structures, called chromosomes. The haploid set of chromosomes is defined as genome.

Structure: Each chromosome consists of two coiled filaments throughout its length called chromonemata by Vejdovsky. These have bead like structures called chromomeres which bear genes. Chromatid is a half chromosome or daughter chromosome. The two chromatids are connected at the centromere or primary constriction. Primary constriction (centromere) and secondary constriction gives rise to satellite. The secondary constriction consists of genes which code for ribosomal RNA and nucleolus hence it is called as "nucleolar organizer region". Chromosomes having satellite are called SAT chromosomes. The ends of chromosomes are called "telomeres" (which do not unite with any other structure).

In 1928 Emile Heitz developed a technique for stainning of chromosomes. Staining property of chromosomes is called as heteropycnosis. Chromosomes can be stained with basic dye like janus green there are two types of regions –

- (1) Heterochromatin: It is formed of thick regions which are more darkly stained than other areas. It is with condensed RNA which is transcriptionally inactive and late replicating. It generally lies near the nuclear lamina. It is of two type:
- (i) **Constitutive hetrochromative :** Occurs in all cells in all stages. *e.g.*, Centromere.
- (ii) Facultative hetrochromative: Formed by inactivation of some gene in some cell in some stages, e.g., Barr body.
- (2) **Euchromatin**: It is true chromatin and is formed of thin, less darkly stained areas. It is with loose DNA which is transcriptionally active and early replicating.

Chemical Composition: DNA - 40%. Histone - 50%. Other (acid) Proteins - 8.5%. RNA - 1.5%. Traces of lipids, *Ca, Mg* and *Fe.* Histone are low molecular weight basic proteins which occur alongwith DNA in 1:1 ratio. Nonhistone chromosomal or NHC proteins are of three types- structural, enzymatic and regulatory. Structural NHC proteins form the core or axis of the chromosome. They are also called scaffold proteins.

Metabolically inactive cell inclusions

Within the cytoplasm of a cell there occur many different kinds of non-living structures which are called inclusions or ergastic / Deutoplasmic substances.

(1) Vacuoles: The vacuole in plants was discovered by Spallanzani. It is a non-living reservoir, bounded by a differentially or selectively permeable membrane, the tonoplast. The vacuole is filled with cell sap or tonoplasm. This cell sap is generally neutral but at maturity it becomes acidic. They contain water, minerals and anthocyanin pigments. These pigments are responsible for the different colours of flowers.

Some protozoans have contractile vacuoles which enlarge by accumulation of fluid or collapse by expelling them from the cell. The vacuoles may be sap vacuoles, contractile vacuoles or gas vacuoles (pseudo vacuoles).

Function of vacuoles : Vacuole maintains osmotic relation of cell which is helpful in absorption of water. Turgidity and flaccid stages of a cell are due to the concentrations of sap in the vacuole.

(2) Reserve food material

The reserve food material may be classified as follows:

- (i) Carbohydrates: Non-nitrogenous, soluble or nonsoluble important reserve food material. Starch cellulose and glycogen are all insoluble.
- (a) Starch: Found in plants in the form of minute solid grains. Starch grains are of two types:

Assimilation starch: It is formed as a result of photosynthesis of chloroplasts.

Reserve starch: Thick layers are deposited around an organic centre called hilum.

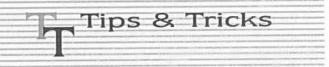

- (b) Glycogen: Glycogen or animal starch occurs only in colourless plants like fungi.
- (c) Inulin: It is a complex type of polysaccharide, soluble and found dissolved in cell sap of roots of Dahlia, Jaruslem, Artichoke, Dandelion and members of compositae.
- (d) Sugars: A number of sugars are found in solution of cell sap. These include glucose, fructose, sucrose, etc.
- (e) **Cellulose**: Chemical formula is $(C_6H_{10}O_5)_n$. The cell wall is made up of cellulose. It is insoluble in water.
- (ii) Fats and Oils: These are important reserve food material. These are always decomposed into glycerol and fatty acids by enzymatic action. Fat is usually abundant in cotyledons than in the endosperm. e.g., flax seed produce linseed oil, castor produce castor oil, cotton seeds produce cottonseed oil, etc.
- (iii) Proteins and Amides (Aleurone grains): Storage organ usually contain protein in the form of crystalline bodies known as crystalloids (potato). Proteins may be in the form of aleurone grains as in pea, maize, castor, wheat, etc.
- (3) Excretory Products: The organic waste products of plants are by-product of metabolism. They are classified as:
- (i) Resins: They are believed to be aromatic compounds consisting of carbon, hydrogen and oxygen and are acidic in nature. Sometimes they are found in combination with gums and are called gum resin. e.g., Asafoetida (heeng).
- (ii) Tannins: They are complex nitrogenous compounds of acid nature having an astringent taste. Presence of tannin in plants makes its wood hard durable and germ proof.
- (iii) **Alkaloids:** These are organic, basic, nitrogenous substance. They occur in combination with organic acids and most of them are poisonous. From plants, cocaine, hyoscine, morphine, nicotine, quinine, atropine, strychnine and daturine etc. are extracted.
- (iv) **Glucosides**: Some glucosides or glycosides function as storage substance e.g., amygdaline of the bitter almond.
- (v) Etherial and Essential oils: These consist mixture of various hydrocarbons known as tarpenes and their oxygen derivatives. They are responsible for flavour of many fruits and scent of many flowers etc. They are volatile and are soluble in water, ether, petroleum etc. e.g., lavender, mint, clove oil, eucalyptus oil, theme oil etc.
- (vi) Mineral matter: Many minerals are waste products in plants.
- (a) Calcium oxalate: It occurs in the form of crystals of various shapes.

Raphides: Needle shaped crystals are known as raphides. e.g., in plants like jamikand, Asparagus, Colocasia, water hyacinth (Jal kumbhi) etc.

Rosette or Sphaeraphides : Star shaped crystals. They occur in special mucilaginous parenchyma cells of the petiole of arum, water hyacinth, etc. Crystals in the form of cubes are found in tunic of onion bulb. In the leaf of belladona, these crystals are in the form of sand and also called as sand crystals.

Calcium oxalate crystals: In members of family solanaceae. They are found as cubics, rods and prisms.

- (b) Calcium carbonate: It is deposited in the form of crystalline masses hanging from a cellulose stalk in enlarged epidermal cells of leaves of Ficus elastica (Indian rubber plant) and is called as cystolith.
- (vii) **Latex**: It is an emulsion in water having many substances either in suspension or in true solution. It may contain sugars, alkaloids and oils. It is watery in banana, milky white in *Euphorbia*, yellow or orange red in opium (poppy) is dried latex.
- (viii) **Organic acids**: Tartaric acid in tamarind, and grapes, citric acid in lemon, orange etc. malic acid in apple and *Bryophyllum*. Oxalic acid in the form of crystals.
- (ix) Gums: It is formed by decomposition of cellulose cell wall. Gum arabic of commerce is obtained from Acacia senegal.

- HPLC stands for high performance liquid chromatography.
- Tracer isotopes / radioactive isotopes : Which functions like normal elements but emit radiations. They can, therefore, be located by Geiger muller counter or scintillalion counter and autoradiography, e.g., ³H, ¹⁴C, ³²P, ³⁵S, etc.
- The smallest cell considered so far is of PPLO (Pleuropneumonia like organisms) or Mycoplasma gallisepticum i.e., 0.1μ .
- ${\it Z}$ Negative charge of the membrane is due to N acetyl neuraminic acid (NANA)/sialic acid.
- Transosomes found in follicular cells of ovary of birds and have triple unit membrane. First reported by Press (1964).
- ✓ Nehar and Sakmann discovered ion-channels in plasma membrane and they were awarded Noble prize for it in 1971.
- Singer and Nicolson's model differs from Robertson's model in the arrangement of proteins.
- Petite character in yeast and cytoplasmic male sterility in maize are examples of mitochondrial inheritance.
- Lehninger discovered oxysomes.
- ✓ In prokaryotic cell, plasma membrane infolding makes a structure mesosome. Which is analogous structure of mitochondria of eukaryotic cell (both part in respiration).
- Chromatophore term was given by Schmitz.
- Autonomic genome system is present in Mitochondria and chloroplast.
- ✓ In confocal microscope, the specimen is illuminated by laser beam.

, Ordinary Thinking

Objective Questions

Tools and Technique

1. Differentiation capacity of compound microscope is

IRPMT 19991

- (a) 0.275 μm
- (b) 2.75 μm
- (c) 27.5 μm
- (d) None
- 2. A mixture containing DNA fragments a, b, c and d with molecular weights of a+b=c,a>b and d>c, was subjected to agarose gel electrophoresis. The positions of these fragments from cathode to anode sides of the gel would be [DUMET 2010]
 - (a) b, a, c, d
- (b) a, b, c, d
- (c) c, b, a, d
- (d) b, a, d, c
- 3. A student wishes to study the cell structure under a light microscope having 10X eyepiece and 45X objective. He should illuminate the object by which one of the following colours of light so as to get the best possible resolution

[CBSE PMT 2005; WB JEE 2008]

- (a) Blue
- (b) Green
- (c) Yellow
- (d) Red
- 4. Electron microscope is used for
- [Kerala CET 2003]
- (a) Viewing structure of the cell
 - (b) Whole mount study
 - (c) Cell division study
 - (d) Structure of the pollen grain
- 5. A magnification of upto 100 million times is possible in

[CBSE PMT 2000; KCET 2001]

- (a) Scanning electron microscope
- (b) Electron transmission microscope
- (c) Scanning probe microscope
- (d) Photon tunneling microscope
- 6. Resolving power of light microscope is IDPMT 20031
 - (a) 0.2 µm
- (b) 0.1 μm
- (c) 2 µm
- (d) 100 μm
- Electron microscope has revealed the presence of or Which among the following can be seen only under electron microscope [AFMC 1996; MP PMT 1998]
 - (a) Ribosome
- (b) Chromosome
- (c) Chloroplast
- (d) Leucoplast
- 8. Who invented the "electron microscope"

[AFMC 2001; BVP 2002; AIIMS 2003; HPMT 2005; MP PMT 2007]

- (a) Knoll and Ruska
- (b) Robert Brown
- (c) Correns
- (d) Janssen and Janssen

- 9. Which of the following statements is/are true
 - A. The resolution power of unaided human eye is 100 micrometre
 - B. The highest resolution is obtained with the light of shortest wavelength
 - Dark field microscope is most useful for viewing the living cells
 - Chromatography is the method of separation of molecular components of the cells present in cytosol
 - E. In gel filtration chromatography, molecules can be separated in picogram to nanogram quantities

[Kerala PMT 2008]

- (a) A, C and D only
- (b) B and D only
- (c) C and E only
- (d) C, D and E only
- (e) A, B and D only
- 10. 1 nm is equal to
- [CPMT 1999; JIPMER 2001]
- (a) 10 Å
- (b) 10⁻³ mm
- (c) 10⁻⁸ m
- (d) 100 μm
- 11. Resolving power of scanning electron microscope is

[DPMT 2007]

- (a) 5 20 nm
- (b) .01 nm
- (c) .1 nm
- (d) .0001
- 12. Fluidity of bio-membranes can be shown by [DUMET 2009]
 - (a) Electron microscope
 - (b) Tissue culture
 - (c) Phase-contrast microscope
 - (d) Fluorescence microscope
- The dry weight of macromolecules like DNA, RNA and proteins can be determined using [Kerala PMT 2009]
 - (a) Fluorescent microscopy
 - (b) Dark field microscopy
 - (c) Phase contrast microscopy
 - (d) Differential interference contrast microscopy
 - (e) Scanning electron microscopy
- 14. The smallest size of a cell which can be seen with unaided eye is or differentiation capacity of human eye is

[RPMT 1999]

- (a) 1 micron
- (b) 10 micron
- (c) 100 micron
- (d) 1000 micron
- 15. Ultrastructure of cell can be best studied by

[CBSE PMT 1999; MP PMT 2003; PET (Pharmacy) 2013]

- (a) Autoradiography
- (b) X-ray diffraction method
- (c) Phase contrast microscope
- (d) None of these
- Which one of the following statements is not true

[Kerala PMT 2009]

- (a) Immersion oil increases the refractive index
- (b) Fluorescent microscopy uses the normal light to view molecules
- (c) Electron microscope has only electromagnetic lenses
- (d) Scanning tunneling microscope is useful in scanning computer chips for defects
- (e) Density gradient centrifugation can be used in the separation of cellular organelles

UNIVERSAL BOOK DEPOT 1960

国籍			BOOK DEPOT 1960
13.	In the cell walls of the guard cells, cellulose microfibrils are oriented [AMU (Med.) 2009]	7.	Lipid molecule in plasma membrane are arranged in
	(a) Radially (b) Transversely		[CPMT 2002; RPMT 2005] (a) Scattered (b) Series
			(c) Alternate (d) Head parallel
14	(c) Tangentially (d) Obliquely	8.	Select of correct statement from the following regarding cell
14.	The chemical substances found most abundantly in the middle lamella is released into the phragmoplast by	0.	membrane [CBSE PMT (Pre.) 2012]
	[EAMCET 2009]		Or
	(a) Endoplasmic reticulum (b) Golgi complex		Who proposed "fluid mosaic model" for plasma membrane [NCERT; RPMT 1999, 2006; BHU 2000, 01;
	(c) Spindle fragments (d) Interzonal fibres		Pb. PMT 2004; Odisha JEE 2004, 11; DPMT 2006;
15.	Which is correct for the structure of cell wall of bacteria and fungi [CPMT 1998; MHCET 2003]		J & K CET 2010; MP PMT 2011]
	(a) Both are made up of cellulose (b) Both have mucopeptide		 (a) Na⁺ and K⁺ ions move across cell membrane by passive transport
	(c) Both are made up of N-acetylglucosamine		(b) Proteins make up 60 to 70% of the cell membrane
	(d) None of these	librati.	 (c) Lipids are arranged in a bilayer with polar heads towards the inner part
16.	In plants, both cellulose and hemicellulose are major components of which one of the following [WB JEE 2016]		 (d) Fluid mosaic model of cell membrane was proposed by Singer and Nicolson
	(a) Plasma membrane (b) Cell wall	9.	Ion carriers are located in [KCET 2000]
	(c) Nuclear membrane (d) Mitochondrial membrane		(a) Nucleus (b) Cell wall
10000	Plasma Membrane		(c) Cellular space (d) Plasma membranes
1.	The plasma membrane consists mainly of	10.	The type of cell junction which facilitates cell to cell communication is [Kerala PMT 2008; AIPMT 2015]
•	[MP PMT 1996, 97, 2001, 12; CBSE PMT 2002;		(a) Tight junction (b) Adhering junction
	Odisha JEE 2008, 11; CBSE PMT (Pre.) 2010]		(c) Gap junction (d) Desmosomes
	(a) Proteins embedded in a carbohydrate bilayer		(e) Brush borders
	(b) Phosholipids embedded in a protein bilayer	11.	Desmosomes are concerned with
	(c) Proteins embedded in a phospholipid bilayer		[CBSE PMT 1995; AIIMS 2010]
	(d) Proteins embedded in a polymer of glucose molecules	7.	(a) Cell division (b) Cellular excretion
2.	For cell membrane, name "plasmalemma" was given by	no care	(c) Cytolysis (d) Cell adherence
	[CPMT 2010]	12.	On which surface of cell Donnan equilibrium occur
	(a) Porter (b) Nageli		[GUJCET 2015]
_	(c) Cramer (d) Plowe		Desmosome is a modification of [MP PMT 2004]
3.	Most abundant Lipid in cell membrane is		(a) Cell wall (b) Tonoplast
	[Odisha JEE 2008; WB JEE 2011] (a) Phospholipid (b) Starch		(c) Plasma membrane (d) Nuclear membrane
	(c) Oil (d) Sulpholipid	13.	According to the 'Unit membrane model' the thickness of the
4.	Beet root if kept in cold water anthocyanin does not come		cell membrane is about [MP PMT 1994]
	out due to plasma membrane [BHU 2003]		(a) 200 nm (b) 7.5 nm
	(a) Differentially permeable	900000	(c) 150 nm (d) 1.0 nm
	(b) Impermeable to anthocyanins	14.	Which of the following does not require carrier molecules
	(c) Permeable to anthocyanins		during transport through cell membranes
	(d) Dead		[BHU 1994; WB JEE 2008]
5.	Which of the following layer is present nearest to plasma		(a) Simple diffusion
	membrane in plant cell [AFMC 2002]		(b) Facilitated diffusion
	(a) Secondary wall (b) Middle lamella	1	(c) Na ⁺ -K ⁺ transport
6.	(c) Primary wall (d) Tonoplast		(d) Active transport of sugars and amino acids
u.	Keeping in view the fluid mosaic model for the structure of cell membrane, which one of the following statements is	15.	Which of the following structures controls the transport of
	correct with respect to the movement of lipids and proteins		the material into and out of living cells or controls
	from one lipid mono layer to the other (described as flip flop		permeability [BHU 1999; Odisha JEE 2005]
	movement) [CBSE PMT 2008, 09]		Or
	(a) While proteins can flip-flop, lipids can not		Which one of the following does not differ in E. coli and
	(b) Neither lipids, nor proteins can flip-flop		Chlamydomonas [CBSE PMT (Pre.) 2012]

(a) Centrosome

(c) Cell wall

(b) Cell membrane

(d) Ribosome

(c) Both lipids and proteins can flip-flop

(d) While lipids can rarely flip-flop, proteins can not

[MP PMT 2003, 09] Thickness of plasma membrane is In eubacteria, a cellular component that resembles 16. [CBSE PMT (Pre.) 2011] (a) 10 Å to 30 Å (b) 30 Å to 50 Å eukaryotic cell is (d) 70 Å to 100 Å (c) 50 Å to 70 Å (b) Plasma membrane (a) Cell wall (c) Nucleus (d) Ribosomes 26. The process of cell eating is called [KCET 2000] (b) Phagocytosis (a) Pinocytosis Which of the following constituent of biological membrane 17. (c) Endocytosis (d) Exocytosis [MP PMT 2002, 03; AIEEE Pharmacy 2004] According to widely accepted "Fluid mosaic model" cell (b) Protein and Phospholipid (a) Phosphoprotein membranes are semi-fluid, where lipids and integral proteins (d) Cellulose (c) Phospholipids can diffuse randomly. In recent years, this model has been [J & K CET 2005] 18. Plasma membrane helps in modified in several respects. In this regard, which of the (a) Transportation of only water in and out of cell following statements is incorrect [NCERT; CBSE PMT 2005] (b) Protein synthesis (a) Proteins in cell membranes can travel within the lipid (c) Osmoregulation bilayer (d) Nucleic acid synthesis Proteins can also undergo flip-flop movements in the lipid bilayer [DPMT 2004] The non-membranous structure is Proteins can remain confined within certain domains of (b) Ribosomes (a) Centrioles the membrane (d) All of these (c) Nucleolus Many proteins remain completely embedded within the Single membrane bound organelles are 20. lipid bilayer [CBSE PMT 1999; DPMT 2004] Which is the latest model that is proposed to explain the 28. (b) Sphaerosome (a) Lysosome structure of plasma membrane (d) All of these [BHU 2001; CBSE PMT 2002; BVP 2003] (c) Glyoxysome Which one of the following is not a constituent of cell (a) Fluid mosaic model (b) Molecular model 21. [CBSE PMT 2007] membrane (c) Unit membrane model (d) None of the above (a) Cholesterol (b) Glycolipids According to mosaic model, plasma membrane is made up of 29. (c) Proline (d) Phospholipids (a) Cellulose and hemicellulose The cell membranes of adjacent cells are fused at this cell 22. (b) Phospholipid and integrate protein [AMU (Med.) 2010, 12] iunction (c) Phospholipid, extrinsic and intrinsic protein (a) Macula adherens (b) Zonula adherens (d) Phospholipid and hemicellulose (c) Zonula occludens (d) Nexus [BVP 2000] Lomasomes are found in 30. In the given figure, the lipid molecules present in plasma 23. (b) Fungal cell (a) Algal cell membrane have polar heads and non - polar tails (d) E. coli (c) Yeast Singer and Nicholson's model of plasma membrane differs Polar head 31. from Robertson's model in the Non-Polar tails (a) Number of lipid layers (b) Arrangement of lipid layers Which of the following figure represents the correct [NCERT] arrangement of lipids in lipids bilayer (c) Arrangement of proteins (d) Absence of protein in Singer and Nicholson's model Carbohydrates are present in the plasmalemma in the form of 32. (a) Starch (b) (a) (b) Cellulose Hemicellulose (glycolipids) and phosphoproteins (d) Phospholipids (glycoproteins) Match the following items in column-I with those in column-33. [WB JEE 2016] II and choose the correct answer Column-I Column-II Hemicellulose P. Plasma membrane mainly contains 24. Bulk drinking of fluid by cells is termed as ii. Calcium pectate lamella Middle [CBSE PMT 1993; CPMT 2000] iii. Proteinaceous filaments mainly composed Or iv. Proteins embedded in of The process of sucking of fluid from the cell surface is called phospholipid bilayer [RPMT 1999] P-i, Q-ii (a) P-ii, Q-i (b) (a) Phagocytosis (b) Pinocytosis P-iii, Q-iv (c) P-iv, Q-ii

(d) Osmosis

(c) Cyclosis

Protoplasm and Cytoplasm

The name 'protoplasm' was given by

[CPMT 1994; MP PMT 1999, 2000; MHCET 2001; Pb. PMT 2004; J & K CET 2005]

- (a) Purkinje
- (b) Hooke
- (c) A.K. Sharma
- (d) Schwann
- 2. Both plants and animals are provided with **[KCET 1998]**
 - (a) Cell wall
- (b) Golgi body
- (c) Chloroplast
- (d) Protoplasm
- 3. Ribonucleoprotein particles of protoplasm are [RPMT 2006]
 - (a) Ribosomes
- (b) Plastid
- (c) Golgi body
- (d) Cristae
- 4. The amount of which of the element is greatest in protoplasm [RPMT 1997, 99]
 - (a) Hydrogen
- (b) Oxygen
- (c) Nitrogen
- (d) Carbon
- Normal pH of Protoplasm is 5.

[RPMT 1999]

- (a) 7.8
- (b) 6.8

(c) 5

- (d) 6.5
- 6. Cyclosis is

- [KCET 1994; RPMT 1997]
- (a) Circular movement of cytoplasm inside the cell
- (b) Up and down movement of protoplasm
- (c) To and fro movement of nucleoplasm
- (d) None of the above
- 7. The term 'cytoplasm' and 'nucleoplasm' were given by

IKCET 20071

- (a) Purkinje
- (b) Strasburger
- (c) Brown
- (d) Flemming
- 8. In higher plants, continuity of cytoplasm from one cell to its neighbouring cells is established through [WB JEE 2012]
 - (a) Apoplast
- (b) Chloroplast
- (c) Leucoplast
- (d) Symplast
- Q Protoplasm is a
- [Pune CET 1998]
- (a) True solution
- (b) Suspension
- (c) Emulsion
- (d) Polyphasic colloidal system
- The substance which makes up about 80% of cytoplasm and has unique structure [Kerala CET 2002]
 - (a) Proteins
- (b) Fats
- (c) Minerals
- (d) Water
- The main arena of various types of activities of a cell is

[CBSE PMT (Pre.) 2010]

Proteins required for functioning of nucleus are formed in [BHU 2012]

- (a) Nucleus
- (b) Plasma membrane
- (c) Mitochondrian
- (d) Cytoplasm
- Protein synthesis in an animal cell, takes place
 - [CBSE PMT 1997]
 - (a) Only in the cytoplasm
 - (b) In the cytoplasm as well as in mitochondria
 - (c) In the nucleolus as well as in the cytoplasm
 - (d) Only on ribose attached to nucleon

Protoplasm was regarded as the "physical basis of life" by

[Odisha JEE 1992; BHU 1992; CPMT 1993; MP PMT 1999; BVP 2000]

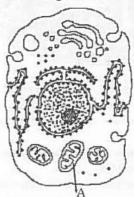

- (a) Huxley (1868)
- (b) Corti (1772)
- (c) Hardy (1899)
- (d) Malphighi (1903)

Mitochondria

Who observed the "mitochondria" first 1.

[PET (Pharmacy) 2013]

- (a) Kolliker
- (b) Robert Brown
- (c) Robert Hooke
- (d) Altmann
- Select the alternative giving correct identification and function of the organelle 'A' in the diagram

[NEET (Karnataka) 2013]

- (a) Mitochondria produce cellular energy in the form of
- (b) Golgi body provides packaging material
- (c) Lysosomes secrete hydrolytic enzymes
- (d) Endoplasmic reticulum synthesis of lipids
- 3. Mitochondria perform all of the following functions except [AFMC 2008]
 - (a) Nucleic acid synthesis
 - (b) β oxidation of fatty acids
 - (c) ATP synthesis
 - (d) Polysaccharide degradation
- 4. In mitochondria, protons accumulate in the

[CBSE PMT (Mains) 2011]

- (a) Intermembrane space
- (b) Matrix
- (c) Outer membrane
- (d) Inner membrane
- 5. Prokaryotic origin of mitochondria was proposed by

[Pune CET 1998]

[MP PMT 1999]

- (a) Rabinowitch (c) Salton
- (b) Altmann and Schimper (d) Morrison
- Mitochondria are related to

6.

- (a) Prokaryotes
- (b) Plasmids
- (c) Plastids (d) Viruses

F₁ particles / oxysome/ elementary particles are present in [RPMT 1995; PUNE CET 1998; CPMT 1999; AFMC 1999; JIPMER 2001; MP PMT 2002; MHCET 2004;

Odisha JEE 2004; AIEEE Pharmacy 20041

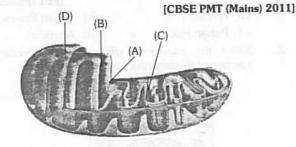

- (a) Endoplasmic reticulum
- (b) Chloroplast
- (c) Mitochondria
- (d) Golgi complex
- The number of mitochondria increases in cells of

[MP PMT 1997]

- (a) Dormant seeds
- (b) Germinating seeds
- (c) Dry seeds
- (d) Dead seeds

- In prokaryotes, the mitochondria are absent. Even then Kreb's cycle takes place. What is the site of Kreb's cycle in [Bihar MDAT 1995]
 - (a) Ribosomes
- (b) Nucleoid
- (c) Cytoplasm
- (d) Mesosomes
- The figure below shows the structure of a mitochondrion with its four parts labelled (A), (B), (C) and (D). Select the part correctly matched with its function

- (a) Part (C): Cristae possess single circular DNA molecule and ribosomes
- (b) Part (A): Matrix major site for respiratory chain enzymes -
- (c) Part (D): Outer membrane gives rise to inner membrane by splitting
- (d) Part (B): Inner membrane forms infoldings called cristae
- What is mitoplast 11.

[WB JEE 2010]

- (a) Membraneless mitochondria
 - (b) Another name of mitochondria
 - (c) Mitochondria without outer membrane
 - (d) Mitochondria without inner membrane
- Rackers particles are found in 12.

[Manipal 2005]

Or

Fernandez Morgan particles are seen in [Odisha JEE 2012]

- (a) Chromosome
- (b) Mitochondria
- (c) Nucleus
- (d) Golgibody
- 13. Folding of inner membrane of mitochondria are called [MHCET 2004; MP PMT 2004, 05; Kerala PMT 2010]
 - (a) Cristae
- (b) Grana
- (c) Calcium oxalate crystals (d) Sacs
- Organelles which are regarded as 'Power house' of the cell and in which the oxidative reactions of the respiratory process [KCET 1994, 2004; Bihar MDAT 1995; takes place are CPMT 2001, 02; MP PMT 2003, 04; RPMT 2005; AFMC 2009]

Which of the following cell organells is responsible for extracting energy from Carbohydrates to form ATP

[NEET 2017]

- (a) Chloroplast
- (b) Ribosomes
- (c) Endoplasmic reticulum
- (d) Mitochondria
- Who first introduced the term 'mitochondrion'

[KCET 1999; Pb. PMT 2004]

- (a) Kolliker
- (b) Robert Brown
- (c) Benda
- (d) Altman

Which of the following cell organelle is considered to be rich 16. [Pb. PMT 1999; in catabolic enzymes

MP PMT 2002, 13; CPMT 2002; DPMT 2003]

Respiratory and oxidative enzymes are present in

[AFMC 1995; CPMT 2001]

Or

Highest number of enzyme is found in

[MP PMT 2007]

- (a) Endoplasmic reticulum (b) Lysosome
- (c) Golgi body
- (d) Mitochondria
- In which of the following parts of mitochondria, succinic [MP PMT 2012] dehydrogenase enzyme is located

In mitochondria, enzyme cytochrome oxidase is present in [MP PMT 2009]

- (a) Outer membrane
- (b) Inner membrane
- (c) Perimitochondrial space (d) Matrix
- [MHCET 2002] The cristae of mitochondria possess 18.
 - (a) Oxysomes
- (b) Peroxisomes
- (c) Nucleosomes
- (d) Quantasomes
- Mitochondria are non-existent in 19.
- [MP PMT 1994, 2011]
 - (a) Red algae
- (b) Some bacteria
- (c) Green algae
- (d) Brown algae
- Mitochondria supply most of the necessary biological energy by 20. [MP PMT 1994]
 - (a) Breaking down of sugar
 - (b) Oxidizing substrates of TCA cycle
 - (c) Reducing NADP
 - (d) Breaking down of protein
- The size of mitochondria in plant cell is [AMU (Med.) 2010] 21.
 - (a) $0.1 1.0 \mu m \log$
- (b) $1.0 4.0 \mu m \log$
- (c) $2.0 4.0 \mu m \log 1$
- (d) $3.0 4.0 \mu m \log$
- Which of the following statements regarding mitochondrial 22. [CBSE PMT 2006] membrane is not correct
 - (a) The inner membrane is highly convolated forming a series of infoldings
 - (b) The outer membrane resembles as sieve
 - (c) The outer membrane is permeable to all kinds of molecules
 - (d) The enzymes of the electron transfer chain are embedded in the outer membrane
- Which one of the following human cells does not contain [WB JEE 2011] mitochondria
 - (a) Nerve cell
- (b) Red blood cell
- (c) Liver cell
- (d) White blood cell
- [MP PMT 2000] Autonomic genome system is present in 24.
 - (a) Ribosomes and chloroplasts
 - (b) Mitochondria and ribosomes
 - (c) Mitochondria and chloroplasts
 - (d) Golgi bodies and mitochondria

UNIVERSAL BOOK DEPOT 1960

The presence of DNA in mitochondria and chloroplast In which plastids are not found 5 [MP PMT 2000] supports the hypothesis that [J & K CET 2002] (a) Blue green algae (b) Bacteria (a) Mitochondria and chloroplast both originated as (c) Fungi (d) All of the above independent free living organisms 6. Which of the following organelles is bounded by two unit Glycolysis occurs in mitochondria and chloroplast both membranes [Pune CET 1998] (c) ATP is produced in mitochondria and chloroplast both (a) Golgi complex (b) Peroxisome (d) Mitochondria and chloroplast undergo meiosis and (c) Chloroplast (d) Lysosome mitosis independent of nucleus 7. What is common between chloroplasts, chromoplasts and 26. Centre of phosphorylation [AFMC 2000] leucoplasts [AIIMS 2008] (a) Peroxisome (b) Oxysome (a) Presence of pigments (c) Ribosome (d) Mitochondria (b) Possession of thylakoids and grana 27. In which part of mitochondria, ATP is generated (c) Storage of starch, proteins and lipids [HPMT 1999; BHU 2003; CPMT 2010] (d) Ability to multiply by a fission-like process (a) Matrix (b) Cristae Which one of the following cellular parts is correctly (c) Outer membrane (d) F₁ particles (oxysomes) 28. The reaction of ATP formation is described [MP PMT 1997; Odisha JEE 2004; (a) Exergonic Endergonic (b) CBSE PMT (Mains) 2012; AIPMT (Cancelled) 2015] (c) Spontaneous (d) Reversible (a) Thylakoids-flattened membranous sacs forming the Identify the membrane across which the proton (H+) grana of chloroplasts 29. gradient facilitates ATP synthesis in a typical eukaryotic cell (b) Centrioles-sites for active RNA synthesis [WB JEE 2012] (c) Ribosomes-those on chloroplasts are larger (80s) while (a) Plasma membrane those in the cytoplasm are smaller (70s) Mitochondrial inner membrane (b) (d) Lysosomes-optimally active at a pH of about 8.5 Mitochondrial membrane Thylakoids are constituents of (d) Nuclear membrane [MP PMT 1997; WB JEE 2010] 30. Mitochondria are semi autonomous as they possess (a) Chloroplasts (b) Mitochondria [WB JEE 2010] (c) ER (d) Ribosomes (b) DNA + RNA In higher plants, the shape of the chloroplast is (c) DNA + RNA + ribosomes (d) Protein [DUMET 2009; MH CET 2015] 31. Which of the following is correct pair [CBSE PMT 1993] (a) Discoid (Lens) (b) Cup-shaped (a) DNA synthesis — Ribosomes (c) Girdle-shaped (d) Reticulate (b) Protein synthesis — Smooth E.R. From the following, select the statement that is true (c) Aerobic respiration — Cristae (d) Suicidal sacs - Dictyosomes [J & K CET 2012] 32. Mitochondria are the site for [MP PMT 1996] (a) All cells have a cell wall (b) Animal cells contain microtubules but plant cells do not (a) Photophosphorylation (b) Oxidative phosphorylation (c) Transpiration (d) Carboxylation contain microtubules (c) The Golgi apparatus is found only in animal cells **Plastids** (d) Chloroplasts are found in plant cells but not in Cell organelles found only in plants 1. [MP PMT 2001] prokaryotic or animal cells (a) Golgi complex (b) Mitochondria The chloroplasts of algae usually lack 12. [MP PMT 1994] (c) Plastids (d) Ribosomes (a) Grana (b) Pigments 2. Green pigment (Chlorophyll) present in plants is (c) Quantasomes (d) Lamellae [AFMC 2002; MP PMT 2005] [AMU (Med.) 2010] Aleuroplasts in a cell store (a) Chromoplast (b) Chloroplast (a) Starch (b) Oil (c) Ribosome (d) Lysosome (c) Protein (d) Nutrients The bright colours of ripe fruits are due to 3. Plant cells differ from animal cells in having [AIEEE Pharmacy 2003] [MP PMT 1995, 98] Or (a) Centrosome (b) Golgi body Which of the following type of plastids does not contain (c) Vacuole (d) Plastid stored food material [NEET (Karnataka) 2013] Select the wrong statement from the following 15. (a) Leucoplasts (b) Chloroplasts [CBSE PMT 2007] (c) Amyloplasts (d) Chromoplasts (a) Both chloroplasts and mitochondria contain an inner Plant cell differ from animal cell because of [MP PMT 2003] and an outer membrane (a) The presence of cell wall and absence of chlorophyll in (b) Both chloroplasts and mitochondria have an internal compartment, the thylakoid space bounded by the (b) The presence of cell wall and chlorophyll in plant cell thylakoid membrane (c) The absence of cell wall and presence of chloroplast in

(d) The absence of cell wall and presence of chlorophyll in

plant cell

- (c) Both chloroplasts and mitochondria contain DNA
- (d) The chloroplasts are generally much larger than mitochondria

16. In chloroplasts, chlorophyll is present in the

[CBSE PMT 2004, 05]

[AIIMS 1998]

- (a) Thylakoids
- (b) Stroma
- (c) Outer membrane
- (d) Inner membrane
- 17. The term chromatophore was coined by
 - (b) Comparethi
 - · (a) Schmitz (c) W. Pfeffer
- (d) Singer and Nicolsan
- 18. Quantasomes are found in

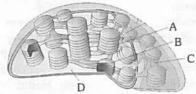

[RPMT 2005; HPMT 2005; MP PMT 2009, 11]

- (a) Mitochondria
- (b) Chloroplast
- (c) Lysosome
- (d) Endoplasmic retiuculum
- 19. The main difference between chlorophyll 'a' and 'b' is
 - (a) Chlorophyll 'a' is linear chain compound and 'b' is branched chain
 - (b) Chlrophyll 'a' has no Mg+ ion in centre of molecule
 - (c) In chlorophyll 'a' there is CH3 group whereas in 'b' it is -CHO group
 - (d) All of the above
- In land plants the guard cells differ from other epidermal 20. [CBSE PMT (Pre.) 2011] cells in having
 - (a) Chloroplasts
- (b) Cytoskeleton
- (c) Mitochondria
- (d) Endoplasmic reticulum
- Match Column I with Column II and select the correct option

(Column – I • Type of Chloroplast)		Column – II (Algae)
A.	Cup shaped	1.	Ulothrix
B.	Girdle shaped	2.	Oedogonium
C.	Stellate	3.	Chlamydomonas
D.	Reticulate	4.	Zygnema

[Kerala PMT 2007]

- (a) A-2, B-4, C-3, D-1 (b) A-3, B-1, C-4, D-2
- (c) A-3,B-4,C-2,D-1 (d) A-4,B-3,C-1,D-2
- (e) A-3, B-4, C-1, D-2
- Water soluble yellowish pigment present in petals of Dahlia is 22. [MP PMT 2004]
 - (a) Carotene
- (b) Xanthophyll
- (c) Anthoxanthin
- (d) Anthocyanin
- Examine the section view of chloroplast showing the 23. different parts

In which of the following options all the four blanks A, B, C [NCERT] and D are correctly identified

- (a) A Granum, B Thylakoid, C Stroma, D Stromal lamella
- (b) A Thylakoid, B Granum, C Stromal lamella, D -Stroma
- (c) A Granum, B Thylakoid, C Stromal lamella, D -Stroma
- (d) A Thylakoid, B Stromal lamella, C Stroma, D -Granum

- Stroma is the ground material of which of the following 24. IMP PMT 20041
 - (a) Lusosomes
- (b) Ribosomes

[AFMC 1997]

IDPMT 2007:

- (c) Chloroplasts
- (d) Mitochondria
- The amyloplasts look like
 - (a) Proplastids
- (b) Elioplast
- (c) Aleuroplast
- (d) Chloroplast
- Which of these is mis-match 26. Kerala PMT 2007, 09, 10; AFMC 2008; CPMT 2010]

(a) Amyloplasts Store protein granules

- Store oils or fats
- (b) Elaioplasts
- Contain chlorophyll pigments (c) Chloroplasts
- (d) Chromoplasts Contain coloured pigments other than chlorophyll
- Contain colourless pigment (e) Leucoplasts
- 27. Red colour of tomato is due to

[Odisha JEE 2004; MP PMT 2011]

- (a) B-carotene
- (b) Anthocyanin
- (c) Lycopene
- (d) Erythrocyanin
- When green tomatoes fruits turn to red, then [AFMC 2003] 28.
 - (a) Chloroplasts are disintegrated and get converted into chromoplasts
 - (b) New chromoplasts are formed
 - (c) Chromoplasts are changed to chloroplasts
 - (d) None of the above
- Extranuclear DNA in the cytoplasm is found inside

[CPMT 1994; AFMC 2012]

- (a) Chloroplast/Mitochondria(b) Ribosome
- (c) Endoplasmic reticulum (d) Golgi apparatus
- All plastids have essentially same structure because

[CBSE PMT 1994]

- (a) They have to perform same function
- (b) They are localized in aerial parts of plant
- (c) All plastids store starch, lipid and proteins
- One type of plastids can be differentiated into another type of plastid depending on cell requirements
- 31. Chromoplast may be of
- [CPMT 1994]
- (a) Orange colour
- (b) Red colour (d) All the above
- (c) Yellow colour 32. The thylakoid in chloroplast are arranged as [BHU 2003]
 - (a) Interconnected disc
- (b) Interconnected sacs
- (c) Stacked discs
- (d) None of these
- Many cells function properly and divide mitotically even 33. [AIIMS 2005] though they do not have
 - (a) Plasma membrane
- (b) Cytoskeleton
- (c) Mitochondria
- (d) Plastids

Endoplasmic reticulum and Golgi body

- Which of the following is a part of endomembrane system of eukaryotic cell [J & K CET 2008]
 - (a) Peroxisomes
- (b) Chloroplasts
- (c) Mitochondria
- (d) Golgi complexes
- Which type of membrane is most abundant within a cell [WB JEE 2008]
 - (a) ER membrane
- (b) Nuclear membrane
- (c) Golgi membrane
- (d) Plasma membrane

			Cell: The Unit of Life 515
3.	The transfer vesicle from RER fuse with which region of golgi complex [CPMT 2000] (a) Cis (b) Medial	13.	Mechanical support, enzyme circulation, protein synthesis and detoxification of drugs are function of [AIIMS 1999; CBSE PMT 2000, 05; AFMC 2006; BHU 2008]
	(c) Trans (d) Protein arms		Or
4.	Nuclear envelope is a derivative of		Which of the following is related to glycosylation of protein
	[AIPMT (Cancelled) 2015]		[CBSE PMT 2000]
	(a) Membrane of Golgi complex		(a) ER (b) Ribosomes
	(b) Microtubules	14.	(c) Dictyosomes (d) Chloroplast The endoplasmic reticulum often bears
	(c) Rough endoplasmic reticulum		[MP PMT 1994; J & K CET 2005]
	(d) Smooth endoplasmic reticulum		(a) Lysosomes (b) Centrioles
5	Endoplasmic reticulum is more developed in [MP PMT 1999]		(c) Peroxisomes (d) Ribosomes
	(a) Green cells (b) Young cells	15.	When the region of endoplasmic reticulum are studded by ribosome on their outer surface of the cisternae, it is called
	(c) Mature cells (d) Bacteriophage		[Pb. PMT 1999; AIIMS 2000]
6.	An interconnecting membranous network of the cell composed of vesicles, flattened sacs and tubules is [KCET 2012]		 (a) Sarcoplasmic reticulum (b) Smooth endoplasmic reticulum (c) Granular endoplasmic reticulum (d) None of the above
	Or Nuclear membrane is formed around the groups of daughter	16.	The cisternae that make up the Golgi complex are
	chromosomes during the telophase by [WB JEE 2016]		[MP PMT 2013] (a) Rough (b) Polarized
	(a) Nucleus (b) Mitochondrion		(c) Non-polarized (d) Reticulate
-	(c) Endoplasmic reticulum (d) Lysosome	17.	The endoskeleton of cell is made up of
7.	See the figure and identify it [NCERT]		[AIEEE Pharmacy 2003; DPMT 2003; BVP 2004; PET (Pharmacy) 2013]
			(a) Cell wall (b) Endoplasmic reticulum
		18.	(c) Cytoplasm (d) Mitochondria "Endoplasmic reticulum" was discovered by [MP PMT 2000]
		10.	(a) Porter (b) Altmann (c) Golgi (d) Benda
	7/1///	19.	RER is mainly concerned with [RPMT 1999]
	Y I I I I		(a) Proteolysis (b) Fatty acids synthesis
			(c) Peptide bond formation (d) Cholesterol synthesis
	(a) RER (b) GB	20.	Which organelle is present in higher number in secretary
	(c) SER (d) None		cells [MP PMT 2007]
8.	Important site for formation of glycoproteins and glycolipids is [NCERT; CBSE PMT (Pre.) 2011]		One of the following serves as a temporary storage place for proteins and other compounds synthesized by endoplasmic
	(a) Lysosome (b) Vacuole		reticulum [AFMC 1993]
	(c) Golgi apparatus (d) Plastid		(a) Dictyosome (b) ER
9.	The most important function of endoplasmic reticulum is		(c) Lysosome (d) Vacuole
	[DPMT 1993; HPMT 2005]	21.	Endoplasmic reticulum is in continuation with
	(a) Protein synthesis (b) Nourishing the nucleus		[BHU 2005; CPMT 2009] (a) Golgibody (b) Nuclear wall
102072270	(c) Secretion of materials (d) To give shape to the cell		(c) Mitochondria (d) Cell wall
10.	In rapidly dividing cells, endoplasmic reticulum is	22.	Golgi body originated from
	[MP PMT 1994]		[CPMT 2002; AFMC 2003; RPMT 2005]
	(a) Highly developed (b) Poorly developed		(a) Lysosome (b) Endoplasmic reticulum
	(c) Absent (d) Non-functional	23.	(c) Mitochondria (d) Cell membrane Which is not function of golgibody [RPMT 1999]
11.	Main function of dictyosomes is [CPMT 2005]		(a) Secretion
	(a) Respiration (b) Storage		(b) Formation of plasmamembrane
	(c) Secretion (d) Breakdown of fats		(c) Fat synthesis
12.	In endoplasmic reticulum the following process take place	0.4	(d) Cell wall formation
	[MP PMT 2001]	24.	Which of the following is the site of lipid synthesis [NCERT; Kerala CET 2002; RPMT 2006;
	(a) Lipid synthesis		AMU (Med.) 2009; NEET 2013; AIIMS 2013;
	(b) Channeling of biosynthetic processes		AIPMT (Cancelled) 2015]
	(c) Steroid synthesis (d) All of the above		(a) Rough ER (b) Smooth ER (c) Golgi bodies (d) Ribosome
	(a) in or the doore		(d) Thousonie

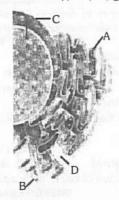

- 25. In plant cells the number of golgi bodies increases during
 - [MP PMT 1997]

- (a) Cell division
- (b) Food synthesis
- (c) Translocation
- (d) Respiration
- 26. The golgi apparatus contains
- [AIIMS 1993]

- (a) DNA
- (b) RNA
- (c) Phospholipids, proteins, enzymes and vitamin C
- (d) Protein-lipid-protein.
- 27. Identify the components labelled A, B, C and D in the diagram below from the list (i) to (viii) given along with

[NCERT]

Components:

- (i) Cristae of mitochondria
- (ii) Inner membrane of mitochondria
- (iii) Cytoplasm
- (iv) Smooth endoplasmic reticulum
- (v) Rough endoplasmic reticulum
- (vi) Mitochondrial matrix
- (vii) Cell vacuole
- (viii) Nucleus

The correct components are

[CBSE PMT (Mains) 2010; NEET 2013]

*	A	В	C	D
(a)	(v)	(iv)	(viii)	(iii)
(b)	(i)	(iv)	(viii)	(vi)
(c)	(vi)	(v)	(iv)	(vii)
(d)	(v)	(i)	(iii)	(ii)

- 28. Golgi bodies are absent in
- [MP PMT 1999]

- -(a) Plants
- (b) Bacteria
- (c) Animals
- (d) Eukaryotic cells
- 29. The Golgi complex plays a major role

[CPMT 1996; NEET 2013]

- (a) In post translational modification of proteins and glycosidation of lipids
- (b) In trapping the light and transforming it into chemical energy
- (c) In digesting proteins and carbohydrates
- (d) As energy transferring organelles
- 30. Secretory and membrane proteins are processed in

[CPMT 2000; MP PMT 2003]

- (a) Peroxisomes
- (b) Glyoxysomes
- (c) Golgi complex
- (d) Sphaerosomes

Lysosome and Ribosomes

- "Lysosomes" were discovered by [Kashmir MEE 1995;
 CPMT 1996; MP PMT 2003; Odisha JEE 2008]
 - (a) Haekel
- (b) De Duve
- (c) De Vries
- (d) Purkinje
- Which of the following statements is incorrect with reference to lysosomes [JIPMER 2002]
 - (a) They are filled acid hydrolase and other enzymes
 - (b) They are monomorphic and uniform in structure and function
 - (c) They may be autophagic
 - (d) They can digest proteins, nuclei acids, lipids and polysaccharides
- 3. The element responsible for the ring structure of chlorophyll and maintenance of ribosome structure is [KCET 2015]
 - (a) Ca++
- (b) Mg^2

(c) S

- (d) K+
- The two sub-units of ribosome remain united at a critical ion level of [RPMT 2001; CBSE PMT 2008]
 - (a) Magnesium
- (b) Calcium
- (c) Copper
- (d) Manganese
- What would happen if lysosomes get ruptured inside the cells in which they are present [MP PMT 1997]
 - (a) Cells will swell
- (b) Cells will shrink
- (c) Cells will die
- (d) Nothing would happen
- Three of the following statements regarding cell organelles are correct while one is wrong. Which one is wrong

[AIIMS 2005]

- (a) Lysosomes are double membraned vesicles budded off from golgi apparatus and contain digestive enzymes
- (b) Endoplasmic reticulum consists of a network of membranous tubules and helps in transport, synthesis and secretion
- (c) Leucoplast are bound by two membranes lack pigment but contain their own DNA and protein synthesizing machinery
- (d) Sphaerosomes are single membrane bound and are associated with synthesis and storage of lipids
- 7. Match List I and List II and select the correct answer using the code given below the list:

	List I	List II				
a	Lysosome	1	Bacteria without cell walls			
b	Mycoplasma	2	A virus that infects bacterial cells			
С	Thylakoid	3	Flattened sacs in a chloroplast			
d	Bacteriophage	4	A vesicle in which hydrolytic enzymes are stored			

			_	
L	o	d	e	

41

[MP PMT 1993]

- (a) a b c d
- (b) a b c d
- 3 1 2 4 (c) a b c d
- (d) a b c d
- 2 3 4 1
- 1 4 2

Cell: The Unit of Life 517 17. The "marker" enzyme of lysosome is [DPMT 2007] Ribosome may also be called [RPMT 2005] (a) Microsome (b) Dictyosome (a) Lysozyme (muramidase) (b) Acid protease (d) Oxysomes (c) Ribonucleoprotein (c) Acid phosphatase (d) Beta-galactosidase Lysosomes are so called because these contain Which of the following is present both in prokaryotic and [MP PMT 1994] [AFMC 2012; WB JEE 2016] eukaryotic cells (a) Carboxylating enzymes (b) Respiratory enzymes (a) Mitochondria (b) Endoplasmic reticulum (c) Oxidizing enzymes (d) Digestive enzymes (c) Ribosomes (d) Nucleus The organelles whose major function is storage of hydrolytic 10. Peptide synthesis inside a cell takes place in [CPMT 1993, 98; MP PMT 1993, 2003, 09; [Odisha JEE 2009; CBSE PMT (Pre.) 2011] CBSE PMT 1996; BVP 2000; HPMT 2005; (a) Ribosomes (b) Chloroplast RPMT 2005; NEET (Phase-II) 2016] (c) Mitochondria (d) Chromoplast 20. Which of the following cell organelles is having single [MP PMT 2007; AFMC 2010] Acid hydrolase is found in layered unit membrane [MP PMT 1995, 98; RPMT 1995; CBSE PMT 2001; CPMT 2005; J & K CET 2005; (a) Centrioles (b) Chromoplasts NEET (Phase-I) 2016] (d) Chloroplasts (c) Lysosomes Or Which of the following subunit of ribosome is composed of In active leaf cells, the double membrane is absent in 23S rRNA and a 5S rRNA +32 different proteins [MP PMT 2013] [Kerala PMT 2006] (a) Centrosome (b) Lysosome Or (c) Mesosome (d) Nucleus The largest subunit of prokaryotic ribosomes is Who discovered "ribosomes" in animal cells 21. [J & K CET 2008] [NCERT; BHU 2001] (b) 70 S (a) 50 S (a) Watson (b) Talvim (c) 30 S (d) 60 S (d) Palade (c) Cowdry (e) 40 S 22. Ribosomes, similar to those of bacteria, are found in The functional unit in the synthesis of protein is [CBSE PMT 2001] [MP PMT 1994; CBSE PMT 1999] (a) Plant nuclei (a) Peroxisome (b) Dictyosome (b) Pancreatic mitochondria (c) Lysosome (d) Polysome (c) Liver endoplasmic reticulum Which one of the following structures is an organelle within (d) Cardiac muscle cytoplasm [CBSE PMT (Mains) 2012] an organelle 23. Which of the following statements is wrong for ribosomes [RPMT 1999] Which of the following cell organelle lacks DNA and (a) Formed by two-sub units bounding membrane [AFMC 2002; AIPMT 2015; (b) Formed by ribo-protein AIPMT (Cancelled) 2015] (c) Formed in chain (a) Ribosome (b) Peroxisome (d) Both sub-units are bounded by a membrane ER (d) Mesosome 24. Ribosomes of bacteria, mitochondria, prokaryotes (Nostoc) (c) and chloroplast are of [MP PMT 1994, 99; MHCET 2001; The cell organelle showing extensive polymorphism is J & K CET 2002; Kerala PMT 2004; Odisha JEE 2010; [MHCET 2004; VITEEE 2008] KCET 2011] (a) Dictyosomes (b) Chloroplasts (a) 50 S type (b) 80 S type (c) Lysosomes (d) Ribosomes (c) 70 S type (d) 30 S type Lysosomes are known as suicidal bags because of All are membrane bound cell organelles except 25. [BHU 1999, 2012; RPMT 1999, 2006; [MP PMT 1997; RPMT 1999; DPMT 2003; BVP 2004; CBSE PMT 2000; MP PMT 2003; HP PMT 2005; **WB JEE 2010**1 J & K CET 2010; PET (Pharmacy) 2013] Or Or Which of the following cell organelles lacks a unit membrane Which one of the following is stored in lysosome [MP PMT 1995, 98; RPMT 2002; J & K CET 2005; **IWB JEE 2016**] Kerala PMT 20101 (a) Mitochondria (b) Hydrolytic enzymes (b) Lysosomes (a) Catalytic enzymes (d) Ribosomes (c) Sphaerosomes (c) Parasitic on nucleus (d) Proteolytic enzymes The 80S ribosomes are present in 16. Ribosomes that occur exclusively in mitochondria is [MP PMT 1996; CPMT 1998] [DPMT 2004] (a) Eucaryotic cells (b) Procaryotic cells (a) 70S (b) 55S (c) Bacterial cells (d) Cyanobacterial cells (c) 30S (d) 50S

(a) DNA and protein

(c) RNA and protein

(b) DNA alone

(d) RNA and DNA

518 Cell: The Unit of Life

Lysosomes have acidic environment inside their vesicles due

[BHU 2012]

(a) Production of carboxylate ions inside it Or (b) Production of phosphate ions inside it Sub unit in prokaryotic ribosome is [DPMT 2007] (c) High pH compared to outside (a) 40 S and 30 S (d) None of the above (b) 50 S and 20 S 28. Polyribosomes are aggregation of [CBSE PMT 2008] (c) 50 S and 30 S (a) Ribosomes and rRNA (d) 60 S and 20 S (b) Only rRNA Ribosome mainly has 37. [DPMT 2004] (c) Peroxisomes (b) RNA (d) Several ribosomes held together by a stearing of mRNA (a) DNA 29. The site of protein synthesis in plants is the (c) Carbohydrate (d) None of these [CPMT 1994; MP PMT 1995, 2003; Eukaryotic 80 S ribosome breaks into MDAT Bihar 1995; KCET 1999; CBSE PMT 1999; [MP PMT 1999, 2000, 03] BVP 2001; BHU 2004; J & K CET 2005, 12; RPMT 2006] (b) 60 S and 40 S (a) 40 S and 40 S Or (d) 50 S and 30 S (c) 60 S and 50 S Which of the following organelle is called as "protein factory of the cell" 39. Which of the following pairs is correct [CBSE PMT 1993] (b) Ribosomes (a) Chloroplast (a) Svedberg unit — Biomembranes (c) Pyrenoids (d) Mitochondria (b) Polyribosomes - RNA The cell organelle associated with intercellular digestion of 30. (c) Dictyosomes - Suicidal sacs macromolecules is [MP PMT 1999, 2002; Kerala PMT 2009] (d) Cisternae - Mitochondria Or What is true about ribosomes 40. [CBSE PMT (Pre.) 2012] Which is concerned with autolysis (a) The prokaryotic ribosomes are 80 S, where "S"stands Or for sedimentation coefficient One of the cell organelle is said to function as "trigger of cell division" (b) These are composed of ribonucleic acid and proteins (a) Lysosome (b) Peroxisome (c) These are found only in eukaryotic cells (c) Polysome (d) Dictyosome (d) These are self-splicing introns of some RNAs (e) Glyoxysome Sphaerosomes, Peroxisomes, 31. Most of the hydrolytic enzymes of lysosome function at Glyoxysomes and Vacuoles [Odisha JEE 2012] (a) Acidic pH (b) Alkaline pH The colour of rose petals is due to water soluble pigments (c) Neutral pH (d) Both (b) and (c) [MP PMT 1994] present in the 32. Ribosomes are found in [MP PMT 2005] (b) Nucleus (a) Cytoplasm (a) Cytoplasm (b) Nucleus (c) Intercellular spaces (d) Vacuoles (c) Cell wall (d) Golgibody Match column I with column II and select the correct option 33. Heterophagosome is [Odisha JEE 2012] (a) Formed by fusion of food containing phagosome with Column II Column I primary lysosome Sap vacuole 1. Contain digestive (b) A newly pinched out vesicle from Golgi apparatus enzyme which fuses with endosome to become fully functional Contractile Store metabolic gases (c) Formed by fusion of primary lysosome with vacuole degenerating intracellular organelles C. Food vacuole 3. Osmoregulation (d) A lysosome in which only indigestible food material is D. Air vacuole 4. Store lipids left Sphaerosomes Store and concentrate 34. Which of the following is responsible for the origin of lysosome mineral salts & nutrients [MP PMT 2009] [RPMT 1997; Kerala PMT 2006] (a) Chloroplast (b) Mitochondria (a) A-5, B-3, C-1, D-2, E-4(d) Ribosome (c) Golgi body (b) A-2, B-3, C-4, D-5, E-1Ribosomes are made up of 35. (c) A-5, B-2, C-3, D-1, E-4[MP PMT 1995, 98, 2006; BVP 2002; CPMT 2004]

(d) A-5, B-3, C-2, D-4, E-1

(e) A-4, B-1, C-3, D-5, E-2

70S type of ribosome shows two units whose sedimentation

[Odisha PMT 2002]

constants are

3. Read the following statements and identify the correct 13. Which one of the following is not a cell inclusion options given [Odisha JEE 2011] Sap vacuoles-contain digestive enzymes with the help (b) Vacuole (a) Crystal of which nutrients are digested options given (c) Starch (d) Fat droplets Contractile vacuoles - take part in osmoregulation and Which of the following is correct in plant cell excretion [Odisha JEE 2008] C. Food vacuoles - store and concentrate mineral salts as (a) Bigger vacuole with rigid cell wall well as nutrients (b) Centriole take part in cell division D. Air vacuoles - store metabolic gases and help in (c) Centrosome are inactive in non-dividing cell buoyancy of cells [Kerala PMT 2008] (d) Absence of cell membrane (a) A and B are correct (b) A and C are correct 15. In germinating seeds fatty acids are degraded exclusively in (c) A and D are correct (d) B and D are correct the [CBSE PMT 2008] (e) B and C are correct (a) Peroxisomes (b) Mitochondria Which is not true about sphaerosomes [Odisha JEE 2004] (c) Proplastids (d) Glyoxysomes (a) Arise from ER. Glyoxysomes occur in (b) Related to fat [Pune CET 1998] (a) Both plant and animal cells (c) Single membrane bound structure (b) Plant cells only (d) Involved in photorespiration 5. Peroxisomes are rich in (c) Animal cells only **IBHU 19991** (d) All types of cells (a) DNA (b) RNA Some of the enzymes, which are associated in converting (c) Catalytic enzymes (d) Oxidative enzymes fats into carbohydrates, are present in [CBSE PMT 1999] 6. Tonoplast is a [CPMT 1996, 98; AFMC 1999; BHU 1999, 2006; BVP 2000; MP PMT 2002, 09; Odisha JEE 2005, 09; HP PMT 2005; Site of gluconeogenesis is [Odisha JEE 2008] DUMET 2009; Kerala PMT 2009] (a) Liposomes (b) Golgi bodies (a) Covering layer of golgi complex (c) Microsome (d) Glyoxysomes (b) Covering layer of vacuoles The osmotic expansion of a cell kept in water is chiefly (c) Covering layer of microbodies regulated by [AFMC 1999; CBSE PMT 2014] (d) Non-living cytoplasmic content (a) Plastids (b) Ribosomes Vacuole in a plant cell [CBSE PMT 2008] (d) Vacuoles (c) Mitochondria (a) Lacks membrane and contains air 19. Which of the following parts of a cell is non-living (b) Lacks membrane and contains water and excretory [CPMT 1993] substances (a) Centriole (b) Vacuole Is membrane-bound and contains storage proteins and (c) Ribosomes (d) Mitochondria lipids The fluid part of cell called cell sap is the Is membrane-bound and contains water and excretory [AIIMS 1993; Manipal 2005] substances (a) Non-living contents of a cell 8. In which one of the following would you expect to find (b) Living contents of a cell glyoxysomes [AIIMS 2005] (c) Non-living contents of the vacuole of cell (a) Endosperm of wheat (b) Endosperm of castor (d) Living contents of the vacuole of cell (c) Palisade cells in leaf (d) Root hairs 'Peroxisome' is the microbody of a cell that helps in Hyaloplasm of vacuole contains IMP PMT 20041 [WB JEE 2016] (a) Air (b) Water (a) Removal of electron and associated hydrogen (c) Water and minerals (d) Nothing (b) Removal of proton DNA remains absent in [MP PMT 2003, 09] (c) Conversion of carbohydrate into fat (a) Chloroplast (b) Nucleus (d) Conversion of carbohydrate into protein (c) Peroxisomes (d) Chromosomes Centrosomes / Centriole What is degraded by Peroxisomes [RPMT 1997] (a) Carbon dioxide (b) Hydrogen peroxide Cilia, Flagella and Microtubules (c) Litheum oxide (d) Carbon monoxide The plane of cell wall formation in a dividing cell is Which one of the following is not considered as a part of the determined by [J & K CET 2012] endomembrane system [CBSE PMT (Mains) 2011] Or Or The filaments associated with cilia and flagella are Which of the following has a single unit membrane constituted by [AIIMS 1994; MP PMT 2000] IMP PMT 19991

(a) Golgi apparatus

(c) Microtubules

(b) Microfilaments

(d) Endoplasmic reticulum

(a) Vacuole

(c) Golgi complex

(b) Lysosome

(d) Peroxisome

2.	Centrioles and	centrosomes are	present in cells of	
	Continuos and			

[MP PMT 1997; HPMT 2005]

- (a) Bacteria
- (b) Cyanobacteria
- (c) Green plants
- (d) Animals
- Function of centriole is

[CPMT 1996; Kerala CET 2002; MP PMT 2003; J & K CET 2005]

- Formation of spindle fibres
- (b) Formation of nucleolus
- Initiation of cell division
- (d) Formation of cell plate
- The function of centrosome is

[CBSE PMT 2000]

- (a) Inhibition of cell division
- (b) Initiates cell division
- (c) To increase protein synthesis
- (d) None of these
- Microtubules are absent in

[AIIMS 2010]

- (a) Mitochondria
- (b) Flagella
- (c) Spindle fibres
- (d) Centriole
- The main structure of centriole is
 - (a) 9 + 3 fibrils
 - (b) 9 + 2 fibrils
 - (c) Nine triplets
 - (d) 13 globular subunits
- A plant cell usually differs from an animal cell in the absence of 7.

[MP PMT 1994, 2002; RPMT 2001; J & K CET 2002; DPMT 2003]

Plant cells normally lack

[AMU (Med.) 2012]

Which of the following organelles is devoid of DNA yet is **IMP PMT 2013**] capable of duplication

- (a) Ribosomes
- (b) Centriole
- (c) Mitochondria
- (d) E.R.

The usual axonemal arrangement of microtubules is 8

[AMU (Med.) 2012]

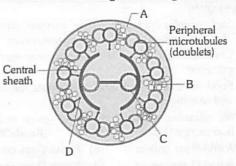

- (a) 6 pairs of doublets radially arranged at periphery with a pair of centrally located microtubules
- (b) 6 pairs of doublets radially arranged at periphery with a single centrally located microtubule
- (c) 9 pairs of doublets radially arranged at periphery with a pair of centrally located microtubules
- (d) 9 pairs of doublets radially arranged at periphery with a single centrally located microtubule
- The solid linear cytoskeletal elements having a diameter of 6 nm and made up of a single type of monomer are known as

[CBSE PMT 2014]

- (a) Intermediate filaments
- (b) Lamins
- (c) Microtubules
- (d) Microfilaments
- Number of protofilaments in microtubule is [DPMT 2007] 10.
 - (a) 10
- (b) 12

(c) 5

See the section of cilia / flagella showing the different parts

In which of the following options all the four blanks A, B, C and D are correctly identified

- A Plasma membrane, B Interdoublet bridge, C -Hub, D - Arm
- (b) A Plasma membrane, B Interdoublet bridge, C -Hub, D - Radial spoke
- (c) A Plasma membrane, B Arm, C Central microtubule, D - Radial spoke
- (d) A Plasma membrane, B Interdoublet bridge, C -Central microtubule, D - Radial spoke
- Pattern of organisation of cilia and flagella is 12.

[Kashmir MEE 1995; AMU (Med.) 2009]

- (a) 9 + 0
- (b) 9+1
- (c) 9+2
- (d) 9 + 3
- Flagella with single strand and composed of flagellin is [J & K CET 2002] found in
 - (a) Prokaryotes
- (b) Eukaryotes
- (c) Both (a) and (b)
- (d) None of these
- Basal bodies of cilia and flagella are derived from 14.

[DPMT 1993]

- (a) Plasma membrane
- (b) Genes
- (c) Centrioles
- (d) Lysosomes
- The principal protein of cilia and flagella is 15.
 - (a) Tubulin
- (b) Albumin
- (c) Globulin
- (d) Gliadin
- In flagellar membrane which enzyme catalyses ATP

[DPMT 2007]

- (a) Cytoplasmic dynein
- (b) Asconic dynein
- (c) Kinesis
- (d) Myosin
- Microtubules are the constituents of [NEET (Phase-I) 2016]
 - (a) Cilia, Flagella and peroxisomes
 - (b) Spindle fibres, Centrioles and Cilia
 - (c) Centrioles, Spindle fibrand Chromatin
 - and Centrioles
- (d) Centrosome, Nucleoso Prokaryotic flagella possess CBSE PMT 1995; BHU 2000] 18.
 - (a) Helically arranged protein molecule
 - (b) Protein membrane enclosed fibre

 - (c) Unit membrane enclosed fibre
 - (d) Microtubular 9+2 membrane enclosed structure
- 19. Microtubule is involved in the
- [CBSE PMT 1998]
- (a) Cell division
- (b) DNA recognition
- (c) Muscle contraction
- (d) Membrane architecture

smooth endoplasmic reticulum Of the above statements

[Kerala PMT 2010]

(a) (A) and (B) only are correct

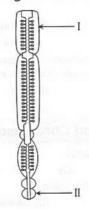

(D) In animal cell steroidal hormones are synthesized by

- (b) (C) and (D) only are correct
- (c) (B) and (D) only are correct
- (d) (A) and (D) only are correct
- (e) (B) and (C) only are correct

- (a) Nuclear sap
- (b) SPM membrane
- (c) Nuclear pore
- (d) None of these
- 9. The nuclear spindle consists of
- - (a) One type of fibre
- [MP PMT 1995, 98]
- (c) Three types of fibres
- (b) Two types of fibres
- Karyology is the study of
- (d) Four types of fibres [JIPMER 1993; AFMC 2008]
- 10. (a) Cell
- (b) Nucleus
- (c) Tissue
- (d) Genes

11. In the given diagram I and II indicate

[MHCET 2015]

- (a) Chromomere and chromonemata
- (b) Centromere and secondary constriction
- (c) Secondary constriction and satellite
- (d) Telomere and satellite
- 12. Spindle fibers attach on to

[NEET (Phase-I) 2016]

- (a) Telomere of the chromosome
- (b) Kinetochore of the chromosome
- (c) Centromere of the chromosome
- (d) Kinetosome of the chromosome
- 13. Nucleoli are rich in

[CBSE PMT 1993; BHU 2001; MP PMT 2003]

- (a) DNA and RNA
- (b) DNA, RNA and proteins
- (c) DNA
- (d) RNA
- 14. Histone proteins found in nuclei of eukaryotes are

[CPMT 2000]

- (a) Acidic
- (b) Basic
- (c) Neutral
- (d) Amphoteric
- 15. The structure of nuclear membrane facilitates

[CPMT 2002; RPMT 2005]

- (a) Synapsis of homologous chromosomes at meiosis
- (b) Nucleo-cytoplasmic exchange of materials
- (c) Anaphasic separation of daughter chromosomes
- (d) Organization of spindles
- 16. The nucleus has

[CBSE PMT 1993]

- (a) One membrane with pores
- (b) Two membranes with pores
- (c) Two membranes with pores through which substances do not pass
- (d) Two membranes with pores through which macromolecules may pass
- 17. Spindle chromosomes have

[CBSE PMT 2000]

- (a) Centriole
- (b) Kinetochore
- (c) Chromocentre
- (d) Chromomere

18. L-shaped chromosomes are called

[MP PMT 1999; BHU 2004]

Or

When the chromosome has a centromere nearer to one end of the chromosome resulting into one shorter and one longer arm, the chromosome is termed as [AMU (Med.) 2012]

- (a) Sex chromosome
- (b) Acrocentric
- (c) Telocentric
- (d) Sub-metacentric
- The telomeres of eukaryotic chromosomes consist of short sequences of [CBSE PMT 2004; AIIMS 2007]
 - (a) Adenine rich repeats
- (b) Guanine rich repeats
- (c) Thymine rich repeats
- (d) Cytosine rich repeats
- Present in nucleolus is
- [MP PMT 2010]
- (a) Golgi complex
- (b) Lysosome
- (c) Mitochondria
- (d) Chromosome
- 21. A tetrad consists of
- IMP PMT 19931
- (a) Four non-homologous chromatids
 - (b) Four non-homologous chromosomes
 - (c) Two sets of homologous chromosomes, each with two chromatids
 - (d) Four homologous pairs of chromosomes
- In nucleoplasm, a conspicuous body of spherical shape attached to a particular chromosome on a definite position is called [AIIMS 1998]
 - (a) Plasmid
- (b) Karyolymph
- (c) Nucleolus
- (d) Nuclear reticulum
- 23. Identify the correct match between types of chromosomes and their descriptions

	Chromosomes		Position of centromere
A.	Metacentric	1.	At the tip
B.	Submetacentric	2.	Almost near the tip
C.	Acrocentric	3.	At the middle
D.	Telocentric	4.	Slightly away from the middle

Description

- (a) A-1, B-3, C-2, D-4
- (b) A-4, B-3, C-2, D-1
- (c) A-1, B-2, C-3, D-4
- (d) A-4, B-3, C-1, D-2
- (e) A-3, B-4, C-2, D-1
- 24. Who showed that the nuclear membrane has many pores or circular structures or annuli
 - (a) Fawcell
- (b) Strasburger
- (c) Butchen
- (d) Callan and Tomlin
- 25. Nucleolemma is a part of
 - (a) Nuclear membrane
- (b) Nuclear reticulum
- (c) Nucleolus
- (d) Nucleoplasm
- Minimum haploid numbers of chromosomes in plant kingdom [RPMT 1999]
 - (a) 3

(b) 2

(c) 1

(d) 4

The given diagram shows a chromosome

Which of the following table refers correctly to the [NCERT] chromosome

Taroni MILIA	No. of centromere	No. of Kinetochore	No. of arms
(a)	1	2	2
(b)	2	2	4
(c)	1	2	4
(d)	2	1	4

- 28. In a cell that is not dividing, the chromosomes are visible as a tangle of fine threads called [MP PMT 1993]
 - (a) Microtubules
- (b) Chromatin
- (c) Microfilaments
- (d) Nucleotin
- The nucleus is separated from surrounding cytoplasm by a nuclear membrane, which is

[MP PMT 1997; Pb. PMT 2004; BHU 2008]

- (a) Single layered with pores
- (b) Single layered without pores
- (c) Double layered with pores
- (d) Double layered without pores
- 30. Nucleoproteins in a cell are synthesized in
 - (a) Outside the nucleolus
- (b) Nucleoplasm
- (c) Nuclear membrane
- (d) Nucleolus

See the following figure and identify it [NCERT] Satellite Secondary Shorter Short arm constriction arm Centromere Centrome Centromere Long arm Longer C В

32. The sex chromosomes of plants were first discovered in

[CMC Vellore 1993]

- (a) Algae
- (b) Fungi
- (c) Pteridophyta
- (d) Flowering plants

- Which of the following are used to define the karyotype of a 33. species
 - The number of chromosomes
 - The chromosome length
 - The positions of the centromeres

IMP PMT 19931

- (a) 1, 2 and 3 are correct
- (b) Only 1 and 2 are correct
- (c) Only 2 and 3 are correct (d) Only 1 and 3 are correct
- 34. The part which does not take strain amongst the following is [CPMT 1993]
 - (a) Chromatid
- (b) Centromere
- (c) Chromatin
- (d) Chromomere
- 35. DNA is mainly found in
- **ICBSE PMT 19991** (b) Nucleus and cytoplasm
- (a) Nucleus only (c) Cytoplasm only
- (d) All of these

- Which of the following is not contained in a eukaryotic 36. [MHCET 2002] nucleus
 - (a) Nucleosome
- (b) Nucleolus
- (c) Chromatin
- (d) Circular DNA molecuels

- 1. A common characteristic feature of plant sieve tube cells and most of mammalian erythrocytes is [NCERT]
 - (a) Absence of mitochondria (b) Presence of cell wall
 - (c) Presence of haemoglobin (d) Absence of nucleus
- 2. Select one which is not true for ribosome
- [NCERT]
- (a) Made of two sub units
 - (b) Form polysome
- (c) May attach to mRNA
- (d) Have no role in protein synthesis
- Which one of these is not a eukaryote
- [NCERT]

[NCERT]

(a) Euglena

3.

- (b) Anabena
- (c) Spirogyra
- (d) Agaricus
- 4. Which of the following dyes is best suited for staining chromosomes [NCERT]
 - (a) Basic Fuchsin
- (b) Safranin
- (c) Methylene blue
- (d) Carmine
- Different cells have different sizes. Arrange the following cells 5. in an ascending order of their size. Choose the correct option among the followings
 - Mycoplasma
- Ostrich eggs
- iii. Human RBC
- Bacteria

Options

- (a) i, iv, iii & ii
- (b) i, ii, iii & iv
- (c) ii, i, iii & iv
- (d) iii, ii, i & iv
- Which of the following features is common to prokaryotes 6. and many eukaryotes [NCERT]
 - (a) Chromosomes present
 - (b) Cell wall present
 - (c) Nuclear membrane present
 - (d) Sub cellular organelles present

- 7. Which of the following statements is true for a secretory cell
 - (a) Golgi apparatus is absent
 - (b) Rough Endoplasmic Reticulum (RER) is easily observed in the cell
 - (c) Only Smooth Endoplasmic Reticulum (SER) is present
 - (d) Secretory granules are formed in nucleus
- 8. What is a tonoplast

[NCERT]

- (a) Outer membrane of mitochondria
- (b) Inner membrane of chloroplast
- (c) Membrane boundry of the vacuole of plant cells
- (d) Cell membrane of a plant cell
- 9. Which of the following is not true of a eukaryotic cell

INCERT

[NCERT]

- (a) It has 80S type of ribosome present in the mitochondria
- (b) It has 80S type of ribosome present in the cytoplasm
- (c) Mitochondria contain circular DNA
- (d) Membrane bound organelles are present
- Which of the following statements is not true for plasma membrane [NCERT]
 - (a) It is present in both plant and animal cell
 - (b) Lipid is present as a bilayer in it
 - (c) Proteins are present integrated as well as loosely associated with the lipid bilayer
 - (d) Carbohydrate is never found in it
- Plastid differs from mitochondria on the basis of one of the following features. Mark the right answer [NCERT]
 - (a) Presence of two layers of membrane
 - (b) Presence of ribosome
 - (c) Presence of chlorophyll
 - (d) Presence of DNA
- Which of the following is not a function of cytoskeleton in a cell [NCERT]
 - (a) Intracellular transport
 - (b) Maintenance of cell shape and structure
 - (c) Support of the organelle
 - (d) Cell motility
- 13. The stain used to visualise mitochondria is
 - (a) Fast green
- (b) Safranin
- (c) Aceto carmine
- (d) Janus green

Critical Thinking Objective Questions

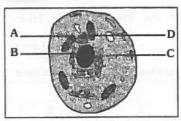

1. Match the following with correct combination

MILL	Column I	1 0 00	Column II
A.	Endoplasmic reticulum	1.	Stack of cisternae
B.	Spherosome	2.	Store oils or fats
C.	Dictyosomes	3.	Synthesis and storage of lipids
D.	Peroxisome	4.	Photorespiration
E.	Elaioplasts	5.	Detoxification of drugs

[Kerala PMT 2008]

- (a) A-5, B-3, C-1, D-4, E-2
- (b) A-5, B-3, C-2, D-4, E-1
- (c) A-2, B-3, C-1, D-4, E-5
- (d) A-3, B-3, C-1, D-5, E-2
- (e) A-3, B-5, C-1, D-4, E-2

2. The RER in the cell synthesised a protein which would be later used in building the plasma membrane. But it is observed that the protein in the membrane is slightly different from the protein made in the RER. The protein was probably modified in another cell organelle. Identify that organelle in the given diagram [KCET 2009]

(a) D

(b) A

(c) B

- (d) C
- 3. Cells obtained from an organism were homogenised and centrifuged. A test indicated that the cells contained glycogen. If you were asked to find out as quickly as possible whether the cells were from a plant or an animal, you would [KCET 2006]
 - (a) Examine the centrifuge for the presence of extracts of chloroplasts
 - (b) Answer immediately that the cells were from a plant source
 - (c) Examine the centrifuge for the presence of extracts of centrioles
 - (d) Answer immediately that the cells were from an animal source
- Cellulose, the most important constituent of plant cell wall is made up of [CBSE PMT 1998; AIIMS 2007]
 - (a) Branched chain of glucose molecules linked by α 1, 6 glycosidic bond at the site of branching
 - (b) Unbranched chain of glucose molecules linked by α 1, 4 glycosidic bond
 - (c) Branched chain of glucose molecules linked by α 1, 4 glycosidic bond in straight chain and α 1, 6 glycosidic bond at the site of branching
 - (d) Unbranched chain of glucose molecules linked by α 1, $\,$ 4 glycosidic bond
- 5. Which of the following statements are false
 - Most cells are tiny and their volume ranges from 1 to 1000 nm³.
 - Some cells have the microvilli to increase the absorptive surface area.
 - C. All cells arise from pre-existing cells.
 - In plants, translocation of solutes is performed by xylem vessels and trachieds.
 - E. According to cell theory all cells arise from abiotic material.

[Kerala PMT 2006]

- (a) A, C and E are false
- (b) A, D and E are false
- (c) B, C and D are false
- (d) C, D and E are false
- (e) A, B and C are false
- Which of the following has centrioles [MP PMT 1994]
 - (a) Chromosomes
- (b) Spindle fibres
- (c) Centrosomes
- (d) Centromeres

7. The diagram of the ultrastructure of a plant cell is given below. Identify the functions of the organelles labelled. A, B, C, D, E in the diagram [KCET 2010]

			E		
	Α	В	C	D	E
(a)	Intracellular transport	Site of oxidative phosphorylation	700 mm / 7	Site of photoph- osphorylation	Storage of cell sap
(b)	Principle director of macromole- cular traffic	Site of oxidative phosphorylation		Site of photop- hosphorylation	
(c)	Site of photophos- phorylation	Storage of cell sap	Intracellular transport	Site of oxidative phosphor- rylation	Principle director of macromolec ular traffic
(d)	Storage of cell sap	Site of oxidative phosphorylation	Principle direction of macromolecular traffic	Site of photophosphor ylation	Intracellular transport

Disulphide bonds which acts as atomic staples to reinforce the conformation of proteins are found in

[AIEEE Pharmacy 2003]

- (a) Endoplasmic reticulum
- (b) Lysosome
- (c) Golgi apparatus
- (d) Cytosol
- Match the columns and identify the correct option 9.

[AIPMT 2015]

Column - I (A) Thylakoids

Column -

- Disc-shaped sacs in golgi apparatus
- (B) Cristae
- (ii) Condensed structure of DNA
- (C) Cisternae
- (iii) Flat membranous sacs in stroma
- (D) Chromatin
- (iv) Infoldings in mitochondria
- (ii) (a) (iii) (iv)
- (ii) (b) (iii) (i) (iv)
- (c) (iii) (ii) (i) (iv)
- (d) (i) (ii) (iv) (iii)
- 10. Consider the following statements
 - A. In prokaryotic cells a special membranous structure formed by the extension of the plasma membrane into the cell is known as polysome
 - B. The smooth endoplasmic reticulum is the major site for synthesis of glycoproteins
 - RuBisCo is the most abundant protein in the whole of biospshere
 - D. Mitochondria, chloroplasts and peroxisomes are not considered as part of endomembrane system

Of the above statements

[Kerala PMT 2012]

- (a) C and D alone are correct
- A and B alone are correct (b)
- B and C alone are correct (c)
- A and D alone are correct
- B and D alone are correct

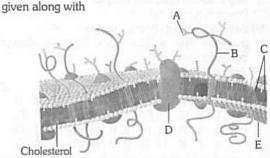

11. Cellular organelles with membranes are

[AIPMT 2015]

- (a) Chormosomes, ribosome and endoplasmic reticulum
- (b) Endoplasmic reticulum, ribosomes and nuclei
- (c) Lysosomes, Golgi apparatus and mitochondria
- (d) Nuclei, ribosomes and mitochondria
- House-keeping proteins occur in

[AMU (Med.) 2010]

- (a) Endoplasmic reticulum (b) Golgi complex
- (c) Cytoskeleton
- (d) All of the above
- Consider the following statements and select the correct option
 - endomembrane system includes plasma membrane, ER, Golgi complex, lysosomes vacuoles
 - B. ER helps in the transport of substances, synthesis of proteins, lipoproteins and glycogen
 - C. Ribosomes are involved in protein synthesis
 - D. Mitochondria help in oxidative phosphorylation and [Kerala PMT 2011] generation of ATP
 - (a) B, C and D are correct
- (b) A alone is correct
- (c) B alone is correct
- (d) C alone is correct
- (e) D alone is correct
- Which of the following four cell structures is correctly matched with the accompanying description [AIIMS 2009]
 - Outer layer of cellulose or (a) Plasma membrane chitin, or absent
 - (b) Mitochondria
- Bacteria like elements with inner membrane forming sacs containing chlorophyll, found in plant cells and algae
- Chloroplasts Bacteria like elements with inner membrane highly folded
- Stacks of flattened vesicles (d) Golgi apparatus
- See the given diagram (cell membrane) and identify the 15. components labelled A, B, C, D and E from the list (i) to (vii)

Components

- (i) Sugar
- (ii) Protein
- (iii) Lipid bilayer
- (iv) Integral protein
- (v) Cytoplasm

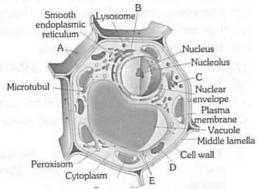

- (vi) Cell wall
- (vii) External protein
- The correct components are

[NCERT]

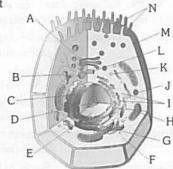

- (a) A (i), B (ii), C (iii), D (vii), E (v)
- (b) A (i), B (ii), C (iii), D (iv), E (vi)
- (c) A (ii), B (i), C (iii), D (iv), E (v)
- (d) A (i), B (ii), C (iii), D (iv), E (v)

 The given figure shows some of the missing structures in a plant cell (A - E). Identify the marked alphabets [NCERT]

- (a) A Tight junction, B Rough endoplasmic reticulum, C
 Golgi apparatus, D Mitochondrion, E Ribosome
- (b) A Plasmodesmata, B Smooth endoplasmic reticulum,
 C Golgi apparatus, D Mitochondrion, E Ribosomes
- (c) A Desmosome, B Rough endoplasmic reticulum, C Golgi apparatus, D Mitochondrion, E Ribosomes
- (d) A Plasmodesmata, B Rough endoplasmic reticulum,C Golgi apparatus, D Mitochondrion, E Ribosomes
- The given diagram shows important structures in an animal cell. Identify it

- (1) The structure replicates during mitosis and generates the spindle
- (II) Major site for synthesis of lipid
- (III) Power house of the cell
- (IV) Store house of digestive enzyme
- (V) Increases the surface area for the absorption of materials
- (VI) Site of glycolysis
- (VII)Site for active ribosomal RNA synthesis [NCERT]
- (a) I M, II A, III H, IV J, V N, VI F, VII D
- (b) I L, II B, III H, IV J, V N, VI F, VII D
- (c) I L, II G, III H, IV J, V N, VI F, VII D
- (d) I L, II G, III H, IV J, V N, VI F, VII D
- 18. Some bacterial cells were fixed for microscopic observation. A structure X was observed on most occasions at the cell membrane
 X

In the above diagram, label X represents

- (a) Mesosome
- (b) Ribosome

INCERT

- (c) Plasmids
- (d) Nucleoid

19. Match the following and select the correct answer

A.	Centriole	(i)	Infoldings in mitochondria
B.	Chlorophyll	(ii)	Thylakoids
C.	Cristae	(iii)	Nucleic acids
D.	Ribozymes	(iv)	Basal body cilia or flagella

[CBSE PMT 2014]

	Α	В	C	D
(a)	(i)	(iii)	(ii)	(iv)
(b)	(iv)	(iii)	(i)	(ii)
(c)	(iv)	(ii)	(i)	(iii)
(d)	(i)	(ii)	(iv)	(iii)

- 20. Mitochondria and chloroplast are
 - (a) Semi-autonomous organelles
 - (b) Formed by division of pre-existing organelles and they contain DNA but lack protein synthesizing machinery

Which one of the following options is correct

[NEET (Phase-I) 2016]

- (a) Both (a) and (b) are correct
- (b) (b) is true but (a) is false
- (c) (a) is true but (b) is false
- (d) Both (a) and (b) are false
- 21. Cytoskeletal network of a cell is built by a process called

[WB JEE 2016]

- (a) Triphasic polymerization (b) Biphasic polymerization
- (c) Trendmilling
- (d) Dynamic instability

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- Assertion : The number of mitochondria in a cell do not correspond to the function of the cell.
 - Reason : Mitochondria are common to both plant and animal cells. [KCET 2006]
- 2. Assertion : Mitochondria and chloroplasts are semiautonomous organelles.
 - Reason : They are formed by division of pre-existing organelles as well as contain DNA but lack protein synthesizing machinery [AIIMS 2005]
- 3. Assertion : A cell membrane shows fluid behaviour.
 - Reason : A membrane is a mosaic or composite of diverse lipids and proteins. [AIIMS 2003]

Answers and Solutions

Tools and Technique

- (a) Differentiation capacity of compound microscope depends upon numerical aperture of the objective lens system and its wavelength (3900-7600 Å). Depending upon the type of visible light used, the resolving power of a light microscope ranges from 0.2 μm to 0.4 μm .
- (a) Electron microscope is predominantly used for viewing 4. of ultrastructure of cell and its organelles. Because it has great magnification and resolving power.
- 7. (a) Electron microscope can magnify the objects upto 2,00,000 times (now possible upto 2,50,000 -4,00,000) and direct of objects is possible on this microscope. Presence of ribosomes (size 23nm in diameter) is revealed with the help of electron microscope.
- (a) Agarose extracted from sea weeds finds use in gel electrophoresis.

- (c) Electromagnetic lenses used in electron microscope having a coil of wire enclosed in soft iron casing.
- **30.** (b) 1 Micrometer (μ m) = 10^{-6} m, 10^{-4} cm, 10^{-3} mm, 1000nm.
- 32. (b) Phase contrast microscope is used to observe living cells and cell organs i.e., spindle fibres, pinocytosis, karyokinesis, cytokinesis etc.
- **33.** (c) Autoradiography is a technique of studying the route of chemicals in chemical reactions taking place inside the cell and organisms with the help of radioactive isotopes i.e., ¹⁴ C, ³ H, ³² P.
- 36. (d) Differential centrifugation: It is a mechanical separation of individual subcellular component from homogenate in centrifuge at different low speeds. Large/heavy/denser particles settle down first at lower speeds while the lighter/smaller/less denser particles do so at higher speeds in centrifuge.

Cell Introduction and Cell theory

- (a) M.J. Schleiden and T. Schwann (1838 39) proposed cell theory.
- (d) Viruses are not applicable to cell theory. They are made up of proteins and one of nucleic acids i.e., DNA or RNA. So they lack protoplasm, the essential part of the cell.
- (b) The prokaryotic cells do not have nuclear membrane while eukaryotic cell have well organised nuclear membrane.
- 4. (b) Because cell organelles are absent in prokaryotes.
- (c) In present time three types of cells are known i.e., prokaryotic, mesokaryotic and eukaryotic.
- 8. (b) Virchow gave 'Omnis cellula a cellula' theory.
- (a) In all living cells water forms 50-80% of total cell contents.
- **14.** (b) Because the membrane which surrounds the vacuole is known as tonoplast.
- (d) Cell organelles like mitochondria, golgi complex, E.R. and lysosomes etc. are present only in eukaryotes.
- 20. (b) Cell was discovered by Robert Hooke in 1965, when he observed tiny cavities bounded by definite walls in the sections of cork.
- 23. (d) Pleuro-pneumonia like organism (PPLO), Mycoplasma gallisepticum is having an average size of $0.150~\mu$.

Cell wall

- (b) Through plasmodesmata, plasmoderm or a fine thread of protoplasm is passing.
- (c) A polysaccharide is made up of many units of monosaccharides.

Plasma membrane

- (b) Anthocyanin pigment cannot come outside due to impermeability of plasma membrane.
- (a) Secondary wall situated near the plasma membrane. After the formation of primary wall.

- (d) According to fluid mosaic model, the arrangement of lipid molecules in plasma membrane is head parallel. It means head of both lipid layer towards the outside.
- (d) Surface of plasma membrane has the ion carriers which participates in exchange of ions.
- **16.** (b) Lipoprotein cell membrane is found in both but ribosomes are of different kinds.
- **21.** (c) Proline is a secondary amino acid which is not found in plasma membrane.
- 27. (b) There are many different proteins embedded in the membrane. Except for flip flop movements rest occurs. Choice (a) is amply demonstrated when the travelling proteins aggregate at sites of endocytosis. Choice (c) type of proteins can be enzymes which are confined to cetrain domains (for e.g., present only on cell surface) choice (d) types are non-trasmembrane proteins.
- (c) According to Singer and Nicolson model, proteins are dispersed in layer of phospholipid.

Protoplasm and Cytoplasm

- (a) Ribosomes are the ribonucleoprotein particles of protoplasm.
- 5. (b) The pH of protoplasm is considered nearly as 7.
- 10. (d) Water is the basic component of the cytoplasm.
- (a) The whole living material of cell is called protoplasm (According to Huxley, 1968).

Mitochondria

- (a) Kolliker (1880), observed mitochondria in striated muscle cell of insect.
- (c) Oxysomes (Elementary particles or inner membranes sub-units or F₁ particles); these are responsible for respiratory chain phosphorylation.
- (d) Infolding of plasma membrane in bacteria are called mesosomes, which are analogous to mitochondria.
- 11. (c) Mitochondria without outer membrane is called as mitoplast.
- 13. (a) Cristae are finger like process projecting inwards.
- 14. (d) Mitochondria are called power house or storage batteries or ATP mills as these are sites of ATP formation (Respiration) through electron transport and oxidative phosphorylation which is used in various metabolic activities/functions of the cell.
- 16. (d) Mitochondria is responsible for the process of respiration which is a catabolic process. Mitochondria is a respiratory organelle where oxidation of stored food material takes place.
- (c) Small DNA particles are present in mitochondria and chloroplast. They can duplicate and work as genetic material.
- (c) Due to presence of 70s ribosome, RNA and ds circular DNA mitochondria is semiautonomous.

Plastids

- (c) Plants are autotrophs and synthesize their food in the process of photosynthesis with the help of chloroplast (plastid).
- (b) The green colour of plants is due to chlorophyll, which is found in chloroplast.
- (d) Chromoplasts develop from proplastids, leucoplasts and chloroplasts. Transformation from chloroplasts is observed during ripening of fruits (e.g., Tomato, Chilli) when they change their colour from green to reddish orange.
- (b) Presence of cell wall and chlorophyll is characteristic feature of plants.
- (d) Plastids are the characteristic feature of photosynthetic eukaryotes. Blue green algae and bacteria are prokaryotes and fungi are saprophytic eukaryotes.
- (a) Thylakoids are bag like structure which stacked as coins one above the other and formed grana.
- (d) Plastids are present in plant cells and absent in most of the animal cells.
- 16. (a) Thylakoids are structural and functional elements of chloroplast, which is made up of quantasome having 230 chlorophyll molecules.
- (a) Guard cells are specialised chlorophyllous epidermal cells.
- **25.** (a) The amyloplasts appear like proplastids. They store starch for a longer period.
- (c) Lycopene is red coloured carotenoide present in chromoplast of tomato.
- 32. (c) The thylakoids of chloroplast are arranged in as stacks of coins or stacks of discs.

Endoplasmic reticulum and Golgi body

- 3. (a) The margins of cisternae of golgi body are slightly curved, so each cisternae has convex cis or forming face toward the nucleus and ER, whereas concave trans or maturing face towards the plasma membrane. It is believed that nuclear membrane and SER the source of small vesicles that fuse with the cis form.
- (c) Golgi complex performs glycosyl transferase activity for addition of glycans on lipids and proteins.
- (a) Because E.R. possesses ribosomes on their membrane which are responsible for protein synthesis.
- 13. (a) Mechanical supports, enzyme circulation are function of both RER and SER while the protein is synthesized by RER and detoxification of drugs by SER.
- (d) Ribosomes are bounded on RER with the help of ribophorin.
- 17. (b) Endoplasmic reticulum gives support to the cell.
- 19. (c) RER has ribosome on which protein synthesis occurs.
- **22.** (b) The formation/origin of new golgi body is always from endoplasmic reticulum, cisternae are similar in both.
- (c) Fat synthesis is the main function of smooth endoplasmic reticulum.

- 24. (b) Smooth endoplasmic reticulum is the part of endoplasmic reticulum on which ribosomes are not present which takes part in lipid synthesis, fat synthesis, glycosylation of carbohydrates, steroid synthesis and detoxification. Whereas rough endoplasmic reticulum is the site of protein synthesis.
- 27. (a) Golgi and ER are often found associated to nuclear membrane.
- (c) Golgi apparatus; because it secretes many types of metabolic enzymes.

Lysosome and Ribosomes

- (b) Because lysosome is polymorphic (primary, secondary, tertiary, autophagic) and polyfunctional cell organelle.
- (c) Cell wall die due to the release of enzyme of lysosome (autolysis).
- 13. (a) Ribosome is present in some cell organelles like mitochondria. Ribosomes are membraneless organelles which are made up of two sub-units and mRNA.
- (c) Lysosomes exist as primary, secondary and tertiary lysosomes.
- **15.** (b) Because it present hydrolytic enzyme, they can digest cell organelles and their parts.
- 16. (b) 55S ribosomes are found in mammalian mitochondria.
- 19. (a) Ribosomes are site of peptide bond formation.
- 21. (d) Ribosomes are also called palade particles.
- **22.** (b) Bacterial ribosomes is 70 S type which resembles with mitochondrial ribosomes.
- 23. (d) Ribosomes are membraneless or without membraneous structure.
- (d) Ribosomes are solid particles of protein and not made up of any membrane.
- 29. (b) Ribosomes are called site of protein synthesis because two sub-units of ribosomes are attached with the thread of mRNA. This mRNA contains anticodes for protein synthesis.
- (a) Because lysosome contains digestive enzymes capable of lysis, thus it is a lytic body or suicidal bag.
- 35. (c) Ribosome is a combination of rRNA and protein.

Sphaerosomes, Peroxisomes, Glyoxysomes and Vacuoles

- (d) Peroxisomes contain glycolic acid oxidase, which oxidises glycolic acid (a product of photosynthesis) to glyoxylic acid.
- 8. (b) Glyoxysomes are enzymes which play a critical role in lipid metabolism in seedlings. Hence they are supposed to be present in endosperm of castor as endosperm of wheat will posses starch.
- (c) DNA not found in peroxisomes, ribosomes, ER, golgibody etc.

Centrosomes / Centriole Cilia, Flagella and Microtubules

- 3. (a) During cell division spindle fibres attached on centriole.
- (d) Microfilaments are ultramicroscopic long, narrow cylindrical solid rods or protein filaments (actin protein) of approx 8 nm in dm.

- (d) T.S. of microtubules shows array of 13 rows of subunit i.e., protofilament having a diameter of 5 – 7 nm.
- **13.** (a) The single stranded flagella occurs in prokaryotes e.g., Bacteria etc. They contain only single stranded and not contain 9 + 2 system.
- 16. (b) The arms of microtubules contain a protein asconic dyenin. It is an ATPase enzyme which catalyzes hydrolysis of ATP to ADP, and transfers the released energy to ciliary/flagellar work.
- 21. (d) Cytoskeleton-Microtubule, Microfilament and Intermediate filaments.
- 23. (d) Microtubules play a role in formation and contraction of the spindle during chromosome movement as well as in cilliary and flagellar motion.

Nucleus and Chromosomes

- (c) Nucleolus was discovered by Fontana. The term nucleolus was given by Bowman.
- (a) Colloidal sap inside the nucleus is known as karyolymph or nucleoplasm.
- 15. (b) Holes in the centre of the nuclear pore provide the main channel through which water soluble molecules shuttle between the nucleus and cytoplasm. This channel also contains a protein called nucleoplasmin which facilitates nucleo-cytoplasm traffic through the pore.
- 17. (b) Chromosomes which adjoins with spindle fibres designated as spindle chromosomes. The position at which the spindle fibre is get attached, known as centromere or kinetochore.
- 19. (b) Eukaryotic telomeric DNA has been shown to consist of simple randomly repeated sequences characterized by clusters of G-residues in one strand and C-residues in the other. Another feature is a 3 overhang (12-16 nucleotides in length) of the G-rich strand.

Critical Thinking Questions

19. (c) Ribozyme is catalytic RNA.

Assertion and Reason

- (e) Several work of cell carried out by mitochondria i.e., ATP synthesis, aerobic respiration, maternal inheritance etc.
- 2. (c) Mitochondria and chloroplasts both are double membrane organelles. They are semi autonomous as both their structure and functions are partially controlled by nucleus of the cell and partially themselves. Both possess their own DNA and arises from pre-existing cells. Synthesis of many amino acids occurs in mitochondria. The first formed amino acids are glutamic acid and aspartic acid.

Also plastid manufactures some of its own proteins, enzymes and other chemicals because of the presence of 70s ribosomes which can help translate the coded information contained in *mRNAs* transcribed over chloroplast DNA.

DNA replication is the process of forming carbon copy of DNA. Whereas transcription is the formation of RNA over DNA template.

- 3. (a) With the help of freeze-fracture techniques in electron microscopy, the fluid mosaic model was put forward in 1970 by S.J. Singer and G.L. Nicolson. According to this model plasma membrane is composed of phospholipids, extrinsic proteins (integral proteins). Selective permeability of plasma membrane can be explained with this model.
- (d) Lysosomes have hydrolytic enzymes. These have no role in photorespiration.
- 5. (a) Of all the membrane associated enzymes, Na⁺,-K⁺ ATPase is one of the most important because of its role in ion transfer across the plasma membrane. This enzyme is dependent on the presence of lipids and is inactivated when all lipids are extracted.
- 6. (d) Number of cells in a multicellular organism are directly proportional to the size of the body. On the other hand, it is a fact that cell vary greatly in their size. Mycoplasma cells are the smallest, ranging from 0.1 to 0.3μm, whereas human cells, generally range from 20 to 30μm. Nerve cells are the longest.
- 7. (a) Metabolic reactions of a living organism can occur only in a delicately balanced environment in the non-living organisms. The cells are the life supporting chambers which have such a special environment. A living cell keeps its chemical composition steady within its boundary.
- (b) Leucoplasts can change to other types of plastids, but chromoplasts can not. Chromoplasts are formed either from leucoplasts or chloroplasts.
- (a) Cell wall is characteristic feature of plant cells. Cell wall absent is animals. Animals cells covered by cell membrane.
- 10. (b) ER functions as cytoskeleton or intracellular and ultrastructural skeletal framework by providing mechanical support to colloidal cytoplasmic matrix. The ER may act as a circulatory system for intracellular circulation of various substances. Membrane flow may also be an important mechanism for carrying particles, molecules and ions into and out of the cells.
- 11. (a) Eukaryotic cells have more DNA than prokaryotic cells because in eukaryotic cells complex chromosomes composed of DNA and histone proteins. But in prokaryotic cells histone protein is absent.
- 12. (d) They are credited with cell theory but the cells are not always the living unit. Cell die and still remain functional such as horny cells in animal and xylem vessels in plants.
- 13. (b) Cell membrane is semi permeable as it allows continuous flow of selected materials across it as required from time to time. On the other hand, constituent molecules of cell membrane are free to move inside membrane.
- (a) In mitochondria ATP production takes place. Therefore, mitochondria is called Power house.

FT Self Evaluation Test

- The term lipochondria was suggested for [MP PMT 2011]
 - (a) Mitochondria
- (b) E. R.
- (c) Golgicomplex
- (d) All of these
- 2. Nucleoid is

[MP PMT 2001]

- (a) A single inactive nucleus having double stranded DNA
- (b) A group of chromosomes associated with proteins
- (c) A nucleus without nuclear membrane and nucleolus or genetic material of prokaryotes
- (d) A chromosome associated with proteins

Biomolecules

3.2

Micromolecules

These are molecules of low molecular weight and have higher solubility. These include minerals, water, amino acid, sugars and nucleotides. All molecules or chemicals functional in life activity are called *biomolecules*.

(1) **Elements**: On the basis of presence and requirement in plants and animals, they are grouped into major (*Ca*, *P*, *Na*, *Mg*, *S*, *K*, *N*) and minor (*Fe*, *Cu*, *Co*, *Mn*, *Mo*, *Zn*, *I*) bioelements.

On the basis of function, they may be of following types:

- (i) Framework elements: Carbon, oxygen and hydrogen.
- (ii) **Protoplasmic elements :** Protein, nucleic acid, lipids, chlorophyll, enzymes, etc.
 - (iii) Balancing elements: Ca, Mg and K.
 - (2) Biological compounds
 - (i) Inorganic compounds: Water 80%, inorganic salts 1-3%.
- (ii) Organic compounds: Carbohydrates (1.0%), Lipids (3.5%), Proteins (12.0%) Nucleotides (2.0%), Other compounds (0.5).
- (3) Cellular pool: Aggregated and interlinked various kinds of biomolecules in a living system. So cell is called cellular pool. It includes over 5000 chemicals. Inorganic chemicals are present mostly in aqueous phase while organic in both, aqueous and nonaqueous. Cellular pool comprises of both crystelloid and colloidal particles. Hence called as crystal colloids.
- (4) Water: Liquid of life, major constituent of cell (about 60-90%) and exists in intracellular, intercellular and in vacuoles. In cells it occurs in free state or bound state (KOH, CaOH etc.).

Properties of water : It is colourless, transparent, tasteless and odourless, neutral (pH-7) liquid. It is universal solvent, as it can dissolve both polar and non-polar solutes. High boiling point due to hydrogen bonding. Shows high degree of cohesion and adhesion. It can undergo three states of matter *i.e.*, solid \rightarrow liquid \rightarrow gas. It is dense and heaviest at 4C and solid below it.

(5) **Carbohydrates**: e.g., sugars, glycogen (animal starch), plant starch and cellulose.

Source of carbohydrate : Mainly photosynthesis. It exists only in 1% but constitutes 80% of the dry weight of plants.

Composition: It consists of carbon, hydrogen and oxygen in the ratio $C_nH_{2n}O_n$. It is also called saccharide and sugars are their basic components. Classification of carbohydrates are:

(i) **Monosaccharides**: These are single sugar units which can not be hydrolysed furthur into smaller carbohydrates. General formula is $C_nH_{2n}O_n$, e.g., Trioses-3C, (Glyceraldehyde, dihydroxyacetone etc.), tetroses-4C, pentoses-5C, hexoses-6C etc.

Important Hexoses

Glucose: $C_6H_{12}O_6$. Grape sugar is dextrose. Grape is sour due to presence of tartaric acid. Fructose is called fruit sugar (sweetest among natural sugars) and glucose is called " sugar of body" (blood sugar). Normal level of blood glucose is 80-120mg/100ml. If it exceeds then condition is called "glucosuria".

Fructose: Occurs naturally in fruit juices and honey. Hydrolysis of cane sugar in body also yields fructose. The sweetest carbohydrate is fructose, which is also called fruit sugar because of its common occurrence in fruits (except grapes). It is also called levulose (because of its laevorotatory nature, *i.e.*, rotates the plane of polarized light towards left). It has a sweetening index of 170 (whereas the sweetening index of glucose is 70).

Galactose: It is called as brain sugar. It's an important constituent of glycolipids and glycoproteins.

Properties of monosaccharide

- ☐ Monosaccharides are colourless, sweet tasting, solids and show oxidation, esterification and fermentation.
- Due to asymmetric carbon, they exist in different isomeric forms. They can rotate polarized light hence they are dextrorotatory and laevorotatory.
- D-glucose after reduction gives rise to a mixture of polyhydroxy alcohol, sorbitol or mannitol.

534 Biomolecules

Functions of monosaccharides

- ☐ Glucose is the ultimate source of ATP in the cell respiration.
 - Polymerisation of these molecules forms macromolecules.
- $\hfill \square$ Ribose and deoxyribose are constituent of nucleic acids and nucleotides.
- \square Sugars have free aldehyde or ketone group which can reduce Cu^{++} to Cu^{+} and are called reducing sugars. Benedicts or Fehling's test are used to confirm the presence of reducing sugars.
- (ii) Oligosaccharides: Formed due to condensation of 2-10 monosaccharide units, the Oxygen bridge is known as "glycoside linkage" and water molecule is eliminated. The bond may be α and β .
- (a) **Disaccharides**: Composed of two molecules of same or different monosaccharide units. Also called "double sugars". Molecular formula is $C_{12}H_{22}O_{11}$.

Maltose: Also called "malt sugar" stored in germinating seeds of barley, oat, etc. It is formed by enzymatic (enzyme amylase) action on starch. It is a double sugar (disaccharide) made up of two molecules on each of α -D glucose and β -D glucose joined by α 1 \rightarrow 4 glycosidic bond. It is a reducing sugar.

Sucrose: "Cane sugar" or " table-sugar". Obtained from sugarcane and beet root and on hydrolysis splits into glucose and fructose. It is a non reducing sugar.

Lactose: Milk sugar or 5% in mammalian milk. On hydrolysis yields glucose and galactose. Streptococcus lactic converts lactose into lactic acid and causes souring of milk.

(b) **Trisaccharides**: Composed of three molecules of sugars. Molecular formula is $C_{18}H_{32}O_{16}$.

Raffinose: Found in sugar beet, cotton and in some fungi. It is made up of glucose, fructose and galactose.

Gentianose: Found in rhizomes of gentian species, made up of glucose and fructose.

- (c) Tetrasaccharides: Composed of four molecules of same or different sugars. Stachyose is found in Stachys tubefera. It is made up of two unit of galactose, one unit of glucose and one unit of fructose.
- (d) **Polysaccharides**: General formula is $(C_6H_{10}O_5)_n$ formed by condensation of several molecules (300-1000) of monosaccharides, (Described under "Macromolecules").
- (6) **Lipids**: Term lipid was coined by Bloor (1943). These are esters of fatty acids and alcohol. They are hydrophobic insoluble in water but soluble in benzene, ether and chloroform. Lipids are classified into three groups:
- (i) **Simple lipids**: These are the esters of fatty acids and glycerol. Again they are typed as:
- (a) Fats and Oils: (Natural lipids or true fats). These are triglycerides of fatty acid and glycerol. Fats which are liquid at room temperature are called oils.

- (b) **Fatty acids**: Obtained by hydrolysis of fats. Formic acid is simplest fatty acid (*HCOOH*). These are of 2 types:
- ☐ Saturated fatty acids: The fatty acids which do not have double bond in between carbon atoms. e.g., butyric acid, palmitic acid, hexanoic acid, etc. They have high melting points and solid at room temperature.
- Unsaturated fatty acids: The fatty acids which have double bonds (D.B.) in carbon atoms. e.g., oleic acid (1 D.B.), linolic acid (2 D.B.), linolenic acid (3 D.B.), arachidmic acid (4 D.B.) one D.B. containing fatty acid is called MUFA, and with more than one D.B. fatty acid is called PUFA. They have lower melting points mostly found in plant fats and liquid at room temperature.

Linoleic acid, linolenic acid, arachidonic acid are essential fatty acid (Evans and Burr 1928). Deficiency of essential fatty acid causes follicular hyper keratosis disease.

(c) Waxes: These are simple lipids composed of one molecule of long chain fatty acid and long chain monohydric alcohol. Waxes have high melting point, insoluble in water. They reduce rate of transpiration by making plant tissue water proof. Wax present in blood called cholestrol.

Bees wax is a common example of wax. It is a combination of palmitic acid and mericyl alcohol $(C_{30}H_{61}OH)$. Candil contains paraffin wax and stearic acid.

- (ii) **Compound lipids**: They contain some additional element. Group with fatty acid and alcohol they may be of following types:
- (a) **Phospholipids**: It is amphipathic molecule. These contain phosphoric acid. It helps in transport, metabolism, blood clotting and permeability of cell membrane. *e.g.*, Lecithin, cephalin (Soyabean oil).
- (b) **Glycolipids**: These contain nitrogen and carbohydrate beside fatty acids. Generally found in white matter of nervous system. *e.g.*, sesocine frenocin.
 - (c) Chromolipids: It includes pigmented lipids e.g., carotene.
- (d) Aminolipids / Sulpholipids : It contains sulphur and amino acids with fatty acid and glycerol. Cutin and suberin are also compound lipids.
- (iii) Derived lipids: These are obtained by hydrolysis of simple and compound lipids. Derived lipids include following components:
- (a) Sterols: Lipids without straight chains are called sterols. They are composed of fused hydrocarbon rings and a long hydrocarbon side chain. Best known sterol is cholesterol.
- (b) Digitalin: It is prepared from leaves of Foxglove (Digitalis lantana) is a heart stimulant.
 - (c) **Ergosterol**: Present in food, found in ergot and yeast.
- (d) **Coprosterol**: It is found in faeces. It is formed as a result of the reduction by bacteria in intestine from the double bond of cholesterol between C_5 and C_6 .
- (e) Terpenes: It is essential oil and present mostly in oils of camphor, eucalyptus, lemon and mint. Phytol is a terpenoid alcohol present in Vitamin A, K, E and in pigments like chlorophyll carotenoid.

Functions of lipids

- Oxidation of lipids yields comparatively more energy in the cell than protein and carbohydrates.
- ☐ The oil seeds such as groundnut, mustard, coconut store fats to provide nourishment to embryo during germination.
- \square They function as structural constituent i.e., all the membrane system of the cell are made up of lipoproteins.
 - Amphipathic lipids are emulsifier.
- \square It works as heat insulator and Used in synthesis of hormones.
 - ☐ Fats provide solubility to vitamins A, D, E, and K.
- (7) **Amino acids**: Amino acids are basic units of protein and made up of C, H, O, N and sometimes S. Amino acids are organic acids with a carboxyl group (-COOH) and one amino group ($-NH_2$) on the α -carbon atom. Carboxyl group attributes acidic properties and amino group gives basic ones. In solution, they serve as buffers and help to maintain pH. General formula is $R-CHNH_2.COOH$. They are 20 in number specified in genetic code and universal in viruses, prokaryotes and eukaryotes. Which take part in protein synthesis.

Amino acids are amphoteric or bipolar ions or Zwitter ions. Amino acids link with each other by peptide bond and long chains are called polypeptide chains. Total known amino acid are more than 200 out of these only 20 amino acid takes part in protein synthesis called protein amino acid.

Classification

(i) Based on R-group of amino acids

Simple amino acids: These have no functional group in the side chain. *e.g.*, glycine, alanine, leucine, valine etc. Glycine is a simplest amino acid.

Hydroxy amino acids: They have alcohol group in side chain. *e.g.*, threonine, serine, etc.

Sulphur containing amino acids: They have sulphur atom in side chain. *e.g.*, methionine, cysteine.

Basic amino acids: They have basic group $(-NH_2)$ in side chain. *e.g.*, lysine, arginine.

Acidic amino acids: They have carboxyl group in side chain. e.g., aspartic acid, glutamic acid.

Acid amide amino acids: These are the derivatives of acidic amino acids. In this group, one of the carboxyl group has been converted to amide $(-CO.NH_2)$. e.g., asparagine, glutamine.

Heterocyclic amino acids: These are the amino acids in which the side chain includes a ring involving atleast one atom other than carbon. *e.g.*, tryptophan, histidine.

Aromatic amino acids : They have aromatic group (benzene ring) in the side chain. e.g., phenylalanine, tyrosine, etc.

(ii) On the basis of requirements: On the basis of the synthesis amino acids in body and their requirement, they are categorized as: **Essential amino acids:** These are not synthesized in body hence to be provided in diet *e.g.*, valine, leucine, isoleucine, theronine, lysine, tryptophan, phenylalanine, methionine etc.

Semi-essential amino acids: Synthesized partially in the body but not at the rate to meet the requirement of individual. *e.g.*, arginine and histidine.

Non-essential amino acids : These amino acids are derived from carbon skeleton of lipids and carbohydrate metabolism. In humans there are 12 non- essential amino acids e.g., alanine, aspartic acid, cysteine, glutamic acid etc. Proline and hydroxyproline have, NH (imino group) instead of NH₂ hence are called imino acids.

(8) Nucleotides: Structurally a nucleotide can be regarded as a phosphoester of a nucleoside. A combination of nitrogenous base and a sugar is called nucleoside and combination of a base, a sugar and phosphate group is known as nucleotide.

N₂ base + Pentose sugar → 'Nucleoside'

Nucleoside + Phosphoric acid \rightarrow 'Nucleotide' + H_2O .

Table: 3.2-1

Types of nitrogen base	Nucleoside	Nucleotide
Adenine	Adenosine	Adenylic acid
Guanine	Guanosine	Guanylic acid
Cytosine	Cytidine	Cytidilic acid
Thymine	Thymidine	Thymidylic acid
Uracil	Uridine	Uridylic acid

There are two types of pentose sugars, ribose found in RNA and deoxyribose found in DNA. There are two types of bases which occur in the nucleic acids.

- (i) **Purines :** Purines are 9 membered double ringed nitrogenous bases which possess nitrogen at 1',3',7' and 9' positions. They are adenine (A) and guanine (G).
- (ii) **Pyrimidines :** They are smaller molecule than purines. These are 6 membered single ringed nitrogenous bases that contain nitrogen at 1' and 3' positions like cytosine (C), thymine (T) and uracil (U). In DNA adenine pairs with thymine by two H_2 bond and cytosine pairs with guanine by three H_2 bond.

A nucleotide may have one, two or three phosphates, as one in AMP, two in ADP. The II and III phosphate bond is called high energy bond and it release about 8 K cal. ATP was discovered by Karl Lohmann (1929). Formation of ATP is endergonic reaction.

Functions of nucleotides

- ☐ Formation of nucleic acids: Different nucleotides polymerize together to form DNA and RNA.
- ☐ Formation of energy carrier: They help in formation of ATP,AMP, ADP, GDP, GTP, TDP,TTP, UDP, etc. which on breaking release energy.
- ☐ Formation of Coenzymes: Coenzymes like NAD, NADP, FMN, FAD, CoA, etc are formed.

536 Biomolecules

Macromolecules

Macromolecules are polymerisation product of micromolecules, have high molecular weight and low solubility. They include mainly polysaccharide, protein and nucleic acids.

(1) **Polysaccharide**: They are branched or unbranched polymers of monosaccharides jointed by glycosidic bond. Their general formula is $(C_6H_{10}O_5)_n$. Polysaccharides are amorphous, tasteless and insoluble or only slightly soluble in water and can be easily hydrolysed to monosaccharide units.

Types of polysaccharides

(i) On the basis of structure

Homopolysaccharides: These are made by polymerisation of single kind of monosaccharides. *e.g.*, starch, cellulose, glycogen, etc.

Heteropolysaccharide: These are made by condensation of two or more kinds of monosaccharides. e.g., chitin, pectin, etc.

(ii) On the basis of functions

Food storage polysaccharides: They serve as reserve food. *e.g.*, starch and glycogen.

Structural polysaccharides: These take part in structural framework of cell wall *e.g.*, chitin and cellulose.

Description of some polysaccharides

Glycogen : It is a branched polymer of glucose and contain 30,000 glucose units. It is also called animal starch. It is also found as storage product in blue green algae, slime moulds, fungi and bacteria. It is a non-reducing sugar and gives red colour with iodine. In glycogen, glucose molecule are linked by 1-4 glycosidic linkage in straight part and 1-6 linkage in the branching part glycogen has branch points about every 8-10 glucose units.

Starch ($C_6H_{10}O_5$): Starch is formed in photosynthesis and function as energy storing substance. It is found abundantly in rice, wheat, legumes, potato (oval and ecentric shaped), banana, etc. Starch is of two types. Straight chain polysaccharides known as amylose and branched chain as amylopectin. Both composed of D – glucose units jointed by $\alpha-1-4$ linkage and $\alpha-1-6$ linkage. It is insoluble in water and gives blue colour when treated with jodine.

Inulin: Also called "dahlia starch" (found in roots). It has unbranched chain of 30-35 fructose units linked by $\beta-2-1$ glycosidic linkage between 1 and 2 of carbon atom of D- fructose unit.

Cellulose: An important constituent of cell wall (20-40%), made up of unbranched chain of $6000~\beta$ –D glucose units linked by 1-4 glycosidic linkage. It is fibrous, rigid and insoluble in water. It doesn't give any colour when treated with iodine. It is a most abundant polysaccharide.

Chitin : It is a polyglycol consisting of N-acetyl-D-glucosamine units connected with $\beta-1,4$ glycosidic linkage. Mostly it is found in hard exoskeleton of insects and crustaceans and some times in fungal cell wall. Second most abundant carbohydrate. It is a most abundant heteropolysaccharide.

Agar-Agar: It is a galactan, consisting of both D and L galactose and it is used to prepare bacterial cultures. It is also used as luxative and obtained from cell wall of red algae *e.g.*, Gracilaria, Gelidium etc.

Pectin: It is a cell wall material in collenchyma tissue may also be found in fruit pulps, rind of citrus fruits etc. It is water soluble and can undergo sol — gel transformation. It contain arabinose, galactose and galacturonic acid.

Neutral sugars: It is found associated with cellulose in cell wall. The common sugars in hemicellulose are D-xylose, L-arabinose, D-galactose, D-mannose and D-glucusonic acid. *e.g.*, hemicellulose.

Gum: It secreted by higher plants after injury or pathogenic attacks. It is viscous and seals the wound. It involves sugars like Larabinose, D-galactose, D-glucusonic acid. e.g., gum arabic.

(2) Mucopolysaccharides: These are gelatinous substance, containing amino sugars, uronic acid, etc. All slimy substances of plant are mucopolysaccharide. e.g., hyaluronic acid, vitreous humour, chondridine sulphate, heparin, husk of isabgol and mucilage also.

Glycoproteins: They include some plasmaprotein and blood group substances. They doesn't contain uronic acid.

Murein: It is a peptidoglycan, linked to short chains of peptides. It is constituent of cell wall of bacteria and blue green algae.

Functions

- (i) Cellulose pectin and chitin are constituents in cell wall of higher plants but peptidoglycan in the cell wall of prokaryotes.
- (ii) They are reserve food material and form protective covering.
 - (iii) Fibres obtained are used in making cloth and rope.
- (iv) Nitrocellulose and trinitrate cellulose (gun-cotton) used as explosive.
- (3) **Protein :** The word protein was coined by Berzelius in 1838 and was used by G. J. Mulder first time 1840. 15% of protoplasm is made up of protein. Average proteins contain 16% nitrogen, 50–55% carbon, oxygen 20–24%, hydrogen 7% and sulphur 0.3-0.5%. Iron, phosphorous,

Structure of proteins : It is due to different rearrangement of amino acids. When carboxyl group (-COOH) of one amino acid binds with amino group $(-NH_2)$ of another amino acid the bond is called peptide bond.

copper, calcium, and iodine are also present in small quantity.

- (i) **Primary structure**: The primary structure is the covalent connections of a protein. It refers to linear sequence, number and nature of amino acids bonded together with peptide bonds only. *e.g.*, ribonuclease, insulin, myoglobin and lysozyme.
- (ii) **Secondary structure**: The folding of a linear polypeptide chain into specific coiled structure (α helix) is called secondary structure. This α helix structure was discovered by Linus Pauling and Robert Corey (1952) using x-ray diffraction technique in silk fibres. *e.g.*, fur, keratin of hair claws, and feathers.

- (iii) **Tertiary structure**: The arrangement and interconnection of proteins into specific loops and bends is called tertiary structure of proteins. It is found in *e.g.*, globular proteins.
- (iv) **Quarternary structure**: It is shown by protein containing more than one peptide chain. The protein consists of identical units. It is known as homologous quarternary structure e.g., lactic dehydrogenase. If the units are dissimilar, it is called as heterogeneous quarternary structure e.g., haemoglobin.

Classification of proteins: Proteins are classified on the basis of their shape, constitution and function.

On the basis of shape

Fibrous protein/Scleroprotein: Insoluble in water. Animal protein resistant to proteolytic enzyme is spirally coiled thread like structure form fibres. *e.g.*, *collagen* (in connective tissue), actin and myosin, keratin in hairs, claws, feathers, etc.

Globular proteins: Soluble in water. Polypeptides coiled about themselves to form oval or spherical molecules *e.g.*, albumin insulin hormones like ACTH, oxytosin, etc.

On the basis of constituents

Simple proteins : The proteins which are made up of amino acids only. *e.g.*, albumins, globulins, prolamines, glutelins, histones, etc.

Conjugated proteins : These are complex proteins combined with characterstic non-amino acid substance called as prosthetic group. These are of following types :

- (i) **Nucleoproteins**: Combination of protein and nucleic acids, found in chromosomes and ribosomes. *e.g.*, deoxyribonucleoproteins, ribonucleoproteins, etc.
- (ii) **Mucoproteins**: These are combined with large amount (more than 4%) of carbohydrates *e.g.*, mucin.
- (iii) **Glycoproteins**: In this, carbohydrate content is less (about 2-3%) e.g., immunoglobulins or antibiotics.
- (iv) **Chromoproteins**: These are compounds of protein and coloured pigments. *e.g.*, haemoglobin, cytochrome, etc.
- (v) Lipoproteins: These are water soluble proteins and contain lipids. e.g., cholesterol and serum lipoproteins.
- (vi) Metalloprotein: These are metal binding proteins, AB₁—globin known as transferring is capable of combining with iron, zinc and copper e.g., chlorophyll.
- (vii) **Phosphoprotein:** They are composed of protein and phosphate e.g., casein (milk) and vitellin (egg).

Derived proteins: When proteins are hydrolysed by acids, alkalies or enzymes, the degredation products obtained from them are called derived proteins.

On the basis of nature of molecules

Acidic proteins: They exist as anion and include acidic amino acids. e.g., blood groups.

Basic proteins: They exist as cations and rich in basic amino acids e.g., lysine, arginine etc.

Function of Proteins

- (i) Proteins occur as food reserves as glutelin, globulin casein in milk.
- (ii) Proteins are coagulated in solutions, alkaline to the isoelectric pH by positive ions such as Zn^{2+} , Cd^{2+} , Hg^{2+} etc. Casein pH 4.6, cyt. C 9.8, resum globulin 5.4, pepsin 2.7, lysozyme 11.0 etc.
 - (iii) Proteins are the most diverse molecule on the earth.
 - (iv) They are biological buffers.
- (v) Monelin is the sweetest substance obtained from African berry (2000 time sweeter than sucrose).
 - (vi) Most abundant protein on earth is RUBP.
 - (vii) Myosin is structural as well as enzymatic protein (ATPase).

Nucleic acids

Nucleic acids are the polymers of nucleotide made up of carbon, hydrogen, oxygen, nitrogen and phosphorus and which controls the basic functions of the cell. These were first reported by Friedrich Miescher (1871) from the nucleus of pus cell. Altmann called it first time as nucleic acid. Nuclein was renamed nucleic acid by Altman in (1889). They are found in nucleus. They help in transfer of genetic information.

Types of nucleic acids: On the basis of nucleotides i.e., sugars, phosphates and nitrogenous bases, nucleic acids are of two types which are further subdivided. These are DNA (Deoxyribonucleic acid) and RNA (Ribonucleic acid).

- DNA (Deoxyribonucleic acids): Term DNA was given by Zacharis.
- (i) **Types of DNA**: It may be linear or circular in eukaryotes and prokaryotes respectively.

Palindromic DNA: The DNA helix bears nucleotide in a serial arrangement but opposite in two strands.

$$-T-T-A-A-C-G-T-T-A-A.....$$

 $-A-A-T-T-G-C-A-A-T-T....$

Repetitive DNA: This type of arrangement is found near centromere of chromosome and is inert in RNA synthesis. The sequence of nitrogenous bases is repeated several times.

Satellite DNA: It may have base pairs upto $1-60\ bp$ and are repetitive in nature. Microsatellite has $1-6\ bp$ and minisatellite has $11-60\ bp$. They are used in DNA matching or finger printing (Jefferey). In eukaryotes, DNA is deutrorotatory and sugars have pyranose configuration.

- (ii) **Chargaff's rule**: Quantitatively the ratio of adenine (A) to thymine (T) and guanine (G) to cytosine (C) is equal. i.e., "Purines are always equal to pyrimidine".
- (iii) C value: It is the total amount of DNA in a genome or haploid set of chromosomes.
- (iv) **Sense and Antisense strand**: Out of two DNA strand one which carries genetic information in its cistrons is called sense strand while the other strand does not carry genetic information, therefore, doesn't produce mRNA. The non-functional DNA strand is called antisense strand.

538 Biomolecules

(v) **Heteroduplex DNA**: Hybrid DNA formed as a result of recombination is called heteroduplex DNA. It contains mismatched base pair of heterologous base sequence.

X-Ray crystallography study of DNA: It was done by Wilkins. It shows that the two polynucleotide chains of DNA show helical configuration.

Single stranded DNA (ssDNA): It is single helixed circular and isolated from bacteriophage $\phi \times 174$ by *Sinsheimer* (1959). It does not follow chargaff's rule. The replicative form (RF) has plus – minus DNA helix. *e.g.*, parvovirus.

Double helical model of DNA: It is also known as Watson and Crick model.

(2) **RNA or Ribonucleic acid**: RNA is second type of nucleic acid which is found in nucleus as well as in cytoplasm *i.e.*, mitochondria, plastids, ribosomes etc. They carry the genetic information in some viruses. They are widely distributed in the cell. Genomic RNA was discovered by **Franklin and Conrat** (1957).

History of cellular enzymes

Enzymes (Gk. en = in; zyme = yeast) are proteinaceous substances which are capable of catalysing chemical reactions of biological origins without themselves undergoing any change. Enzymes are **biocatalysts**. Enzymes exist inside the cell in colloidal form. An enzyme may be defined as "a protein that enhances the rate of biochemical reactions but does not affect the nature of final product". Like the catalyst the enzymes regulate the speed and specificity of a reaction, but unlike the catalyst they are produced by living cells only. All components of cell including cell wall and cell membrane have enzymes.

Maximum enzymes (70%) in the cell are found in mitochondrion. Enzymes are also called 'biological middle man'. The study of the composition and function of the enzyme is known as enzymology.

The term enzyme (meaning in yeast) was used by Willy Kuhne (1878) while working on fermentation. At that time living cells of yeast were thought to be essential for fermentation of sugar. Edward Buchner (1897), a German chemist proved that extract zymase, obtained from yeast cells, has the power of fermenting sugar (alcoholic fermentation). Zymase is complex of enzymes (Buchner isolated enzyme for the first time).

Later J.B. Sumner (1926) prepared a pure crystalline form of urease enzyme from Jack Bean (*Canavalia ensiformis*) and suggested that enzymes are proteins. Northrop and Kunitz prepared crystals of pepsin, trypsin and chymotrypsin. Arber and Nathans got noble prize in 1978 for the discovery of restriction endonucleases which break both strands of DNA at specific sites and produce sticky ends. These enzymes are used as microscissors in genetic engineering.

Nature of enzymes

Mostly enzymes are proteinaceous in nature. With some exception all enzymes are proteins but all proteins are not enzymes. Enzymatic protein consist of 20 amino acids. The polypeptide chain or chains of an enzyme show tertiary structure. Their tertiary structure is very specific and important for their biological activity. Loss of tertiary structure renders the enzymic activity.

Some enzymes like pepsin, amylase, urease, etc., are exclusively made up of protein i.e., simple proteins. But most of the other enzymes have a protein and a non-protein component, both of which are essential for enzyme activity. The protein component of such enzymes is known as **apoenzyme** whereas the non-protein component is called **cofactor** or **prosthetic group**. The apoenzyme and prosthetic group together form a complete enzyme called **holoenzyme**.

Activity of enzyme is due to co-factor, which can be separated by dialysis. co-factor is small, heat stable and may be organic or inorganic in nature.

Three types of cofactors may be identified. Prosthetic group, coenzyme and metal ions.

Prosthetic group : Prosthetic groups are organic compounds distinguished from other cofactors in that they are permanently bound to the apoenzyme, e.g., in peroxisomal enzymes peroxidase and catalase which catalyzes breakdown of hydrogen peroxide to water and oxygen.

Coenzymes : Fritz Lipmann discovered coenzymes. Coenzymes are also organic compounds but their association with the apoenzyme is transient, usually occurring only during the course of catalysis.

In general coenzymes not only assist enzymes in the cleavage of the substrate but also serve as temporary acceptor for one of the product of the reaction. The essential chemical component of many coenzymes are vitamins, e.g., coenzyme nicotinamide adenine dinucleotide (NAD), nicotinamide adenine dinucleotide phosphate (NADP) contains the vitamin niacin, coenzyme A contains pantothenic acid, flavin mononucleotide (FMN), flavin adenine dinucleotide (FAD) contains riboflavin (Vitamin B₂), and thiamine pyrophosphate (TPP) contains thiamine (Vitamin B₁).

Metal ions: A number of enzymes require metal ions for their activity. The metal ions form coordination bonds with specific side chains at the active site and at the same time form one or more coordination bonds with the substrate. The latter assist in the polarization of substrate bonds to be cleaved by the enzyme. The common metal ions are Zn^{++} , Cu^{++} , Mg^{++} .

Inorganic part of enzyme acts as prosthetic group in few enzymes they are called activators. These activators are generally metals. Hence these enzymes are called Metalloenzyme such as:

Table: 3.2-2 Enzymes activators

Activators	Enzymes	
Iron (Fe)	Acotinase, Catalase and Cytochrome oxidase	
Zinc (Zn)	Alcohol dehydrogenase, Carbonic anhydrase	
Copper (Cu)	Tyrosinase, Cytochrome oxidase	
Magnesium (Mg)	Hexokinase, Phosphotransferase	
Manganese (Mn)	Peptidase, Decarboxylase	
Molybdenum (Mo)	Nitrate reductase	
Nickel (Ni)	Urease	
Boron	Enolase	

Nomenclature and Classification

Dauclax, (1883) introduced the nomenclature of enzyme. Usually enzyme names end in suffix-ase to the name of substrate e.g., Lactase acts on lactose, maltase act on maltose, amylase on amylose, sucrase on sucrose, protease on proteins, lipase on lipids and cellulase on cellulose. Sometimes arbitrary names are also popular e.g., Pepsin, Trypsin and Ptylin etc. Few names have been assigned on the basis of the source from which they are extracted e.g., Papain from papaya, bromelain from pineapple (family Bromeliaceae). Enzymes can also be named by adding suffix—ase to the nature of chemical reaction also e.g., Oxidase, dehydrogenase, catalase, DNA polymerase.

Modern names are given after chemical action. They are more systematic, informative but slightly longer. e.g., ATP: D-glucose phosphotransferase.

Common simpler names used at the place of systematic names called **trivial names**.

According to older classification: The older classification of enzymes is based on the basis of reactions which they catalyse. Many earlier authors have classified enzymes into two groups:

(1) **Hydrolysing enzyme**: The hydrolysing enzymes of hydrolases catalyse reactions in which complex organic compounds are broken into simpler compounds with the addition of water. Hydrolytic reactions are reversible. Depending upon the substrate hydrolysing enzymes are:

Carbohydrases: Most of the polysaccharides, disaccharides or small oligosaccharides are hydrolysed to simpler compounds, e.g., hexoses or pentoses under the influence of these enzymes.

Lactase on lactose to form glucose to galactose, sucrase/invertase on sucrose to form glucose and fructose, amylase or diastase on starch to form maltose, maltase on maltose to form glucose, cellulase on cellulose to produce glucose.

Easterases: These enzymes catalyse the hydrolysis of substances containing easter linkage, e.g., fat, pectin, etc. into an alcoholic and an acidic compound.

Fat — Lipase → Glycerol + Fatty acid

Phosphoric acid easters — Phosphatase >

Phosphoric acid + Other compounds

Proteolytic enzymes : The hydrolysis of proteins into peptones, polypeptides and amino acids is catalysed by these enzymes

Protein Pepsin Peptones

Polypeptides - Peptidases - Amino acids

Amidases: They hydrolyse amides into ammonia and acids.

Urea - Urease Ammonia + Carbon dioxide

Asparagine Asparaginase Ammonia + Aspartic acid

(2) **Desmolysing enzymes :** Most of the desmolysing enzymes are the enzymes of respiration *e.g.*, oxidases, dehydrogenases, (concerned with transfer of electrons), transaminases carboxylases etc.

According to IUB system to classification: In 1961 the Commission on enzymes set up by the 'International Union of Biochemistry' (IUB) framed certain rules of their nomenclature and classification.

According to IUB system of classification the major points are :

- ☐ Reactions (and enzymes catalyzing them) are divided into 6 major classes each with 4-13 subclasses.
- ☐ The enzyme name has two parts-first name is of substrate. The second ending in ase indicates type of reaction.
- ☐ The enzyme has a systematic code No. (Enzyme code/Enzyme Commission). The first digit denotes the class, the second sub-class, the third sub-sub-class and the fourth one is for the particular enzyme name. Thus, E.C. 2.7.1.1 denotes class 2 (Transferases)-subclass 7 (transfer of phosphate) sub-sub-class 1 (an alcohol functions as phosphate acceptor). The 4th digit indicates hexokinase. Major classes of enzymes are as follows:
- (i) Oxidoreductases: These enzymes catalyse oxidation reduction reactions, usually involving the transfer of hydrogen atoms or ions from one molecule to another. There are three main types of these enzymes:

Oxidases: Where the hydrogen is transferred from a molecule to oxygen, e.g., cytochrome oxidase. They play very important role in E.T.S. in photosynthesis as well as respiration,

Dehydrogenases: Where the hydrogen is transferred to a coenzyme such as NAD⁺, e.g., Succinic dehydrogenase. They help in oxidation of organic molecules during aerobic respiration.

Reductase: It is cause of addition of hydrogen or an electron and remove oxygen. e.g., Nitrate reductase requires NAD (coenzyme I) as coenzyme for the reaction.

- (ii) **Transferases:** These enzyme catalyse the transfer of a specific group (e.g., amino, methyl, acyl, phosphate) from one kind of molecule to another e.g., transphosphorylases, transaminases, transpeptidases, transmethylases, kinases, etc.
- (iii) **Hydrolases**: These enzyme catalyse the hydrolysis of organic foods i.e., the breakdown of large molecules by addition of water. Most of the hydrolysing (digestive) enzymes are located in lysosomes. e.g., all digestive enzymes such as lipases (digest the stored food material of castor seeds) amylases, esterases, phosphatases, carbohydrases, proteases.
- (iv) **Lyases** (Desmolases): These enzymes catalyse the breakage of specific covalent bonds and removal of groups without hydrolysis e.g., fumerases, carboxylases, aminases, histidine decarboxylase that splits C-C-bond of histidine, forming CO_2 and histamine.
- (v) **Isomerases :** These enzymes catalyse the rearrangement molecular structure to form isomers. *e.g.*, phosphohexose isomerase (phosphoglucomutase) act on glucose 6-phosphate to form fructose 6-phosphate (both C_6 compounds); epimerase, racemase.
- (vi) **Ligases or Synthetases**: These enzymes form bonds and join two molecules together, using energy supplied from the breakdown of ATP, e.g., DNA ligase is used to repair breaks in DNA molecules. Amino-Acyl synthetase is used to activate t-RNA by attaching amino acid at 3' end. Tryptophan synthetase is used to convert tryptophan amino acid to IAA.

Site of enzyme action

All enzymes are produced in the living cells. About 3,000 enzymes have recorded. These are of two types with regard to the site where they act as:

Intracellular enzymes: Most of the enzymes remain and function inside the cells, They are called the intracellular enzymes or endoenzymes. Some of these enzymes are found in cytoplasmic matrix. Certain enzymes are bound to ribosomes, mitochondria and chloroplast etc.

Extracellular enzymes : Certain enzymes leave the cells and function outside them. They are called the extracellular enzymes or exoenzymes. They mainly include the digestive enzymes. e.g., salivary amylase, gastric pepsin, lysozyme present in tears and nasal secretion.

Rennet tablets with enzyme rennin from calf's stomach are widely used to coagulate protein caseinogen for cheese (casein) formation.

Mechanism of enzyme action

Energy is required to bring the inert molecules into the activated state. The amount of energy required to raise the energy of molecules at which chemical reaction can occur is called activation energy. Enzymes act by decreasing the activation energy so that the number of activated molecules is increased at lower energy levels. If the activation energy required for the formation of the enzyme-substrate complex is low, many more molecules can participate in the reaction than would be the case if the enzyme were absent.

Mode of enzyme action

In 1913 Michaelis and Menten proposed that for a catalylic reaction to occur it is necessary that enzyme and substrate bind together to form an enzyme substrate complex.

$$E + S \rightarrow E - S Complex$$
(Enzyme) (Substrate) \leftarrow (Enzyme-substrate Complex)

$$E - S Complex \rightarrow E + P (Product)$$

It is amazing that the enzyme-substrate complex breaks up into chemical products different from those, which participated in its formation (i.e., substrates). On the surface of each enzyme there are many specific sites for binding substrate molecules called **active sites** or catalytic sites.

There are two views regarding the mode of enzyme action:

Lock and Key hypothesis (Template hypothesis): The hypothesis was put forward by Emil Fisher (1894). According to this hypothesis the enzyme and its substrate have a complementary shape. The specific substrate molecules are bound to a specific site of the enzyme molecule.

The theory can be explained easily by the fact that a particular lock can be opened by a particular key specially designed to open it. Similarly enzymes have specific sites where a particular substrate can only be attached. The lock and key model accounts for enzyme specificity.

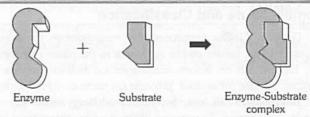

Fig: 3.2-1 Lock and key model of enzyme action

Induced fit hypothesis: This hypothesis was proposed by Daniel, E. Koshland (1959).

According to this view, active site is not rigid but static and it has two groups – buttressing group and catalytic group. Initially substrate bind to the buttressing group which induces the catalytic group to fit the substrate and catalytic group weaks the bonds of reactant or substrate by electrophilic and nucleophilic forces.

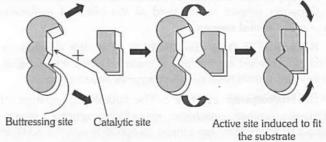

Fig: 3.2-2 Induced fit model of enzyme action

Properties of enzymes

Molecular weight: Enzymatic proteins are substances of high molecular weight. Bacterial ferredoxin one of the smaller enzymes has molecular weight of 6,000, where as pyruvic dehydrogenase one of the largest-has a molecular weight of 4600000.

Amphoteric nature : Each molecule of enzyme possess numerous groups which yield H^+ in slightly alkaline solutions and groups which yield OH^- ions in slightly acidic solutions. Unlike many other substances, therefore, the enzymatic protein is amphoteric, i.e., capable of ionizing either as an acid or as a base depending upon the acidity of the external solution.

Colloidal nature: All enzymes are colloidal in nature and thus provide large surface area for reaction to take place. They posses extremely low rates of diffusion and form colloidal system in water.

Specificity of enzyme: Most of the enzymes are highly specific in their action. A single enzyme will generally catalyze only a single substrate or a group of closely related substrates. The active site possess a particular binding site which complexes only with specific substrate. Thus, only a suitable substrate fulfils the requirements of active site and closely fixes with it. The specificity of enzyme is determined by sequence of amino acids in the active sites.

Heat specificity: The enzymes are thermolabile *i.e.*, heat sensitive. They function best at an optimum temperature $(20^{\circ}C-40^{\circ}C)$. Their activity decrease with decrease as well as increase in temperature and stops at $0^{\circ}C$ and above $80^{\circ}C$.

UNIVERSAL BOOK DEPOT 1960

Catalytic properties: Enzymes are active in extremely small amounts, e.g., one molecule of invertase can effectively hydrolyze 1,000,000 times its own weight of sucrose. One molecule of catalase is able to catalyze conversion of 5,000,000 molecules of hydrogen peroxide.

Reversibility of reaction: The enzyme-controlled reactions are reversible. The enzymes affect only the rate of biochemical reactions, not the direction. e.g., Lipase can catalyse splitting of fat into fatty acids and glycerol as well as synthesis of fatty acids and glycerol into fats.

Fat Glycerol + Fatty acid

pH sensitivity: The enzymes show maximum activity at an optimum pH is $6-7.05(7\pm1.05)$. Their activity slows with decrease and increase in pH till it stops. Each enzyme has its own different favourable pH value.

High efficiency: The effectiveness of an enzymatic reaction is expressed in terms of its turn over number or catalytic centre activity means number of substrate molecules on which one enzymes molecules acts in one minute.

Turn over number depends on the number of active sites of an enzyme. An active site is an area of the enzyme which is capable of attracting and holding particular substrate molecules by its specific charge, size and shape so as to allow the chemical change. Enzymes show 3-D structure. R (alkyl) groups of amino acids form active sites during folding polypeptide chains. Usually 3-12 amino acids form an active site.

Highest turn over number is of **carbonic anhydrase** (36 million/min or 600000 per second) and lowest is of lysozymes (30/min or 0.5 per second). So carbonic anhydrase is fastest enzyme. The lowest turn over number is of lysozymes.

Enzyme inhibition

Competitive inhibition: Substances (inhibitors) which are structurally similar to the substrates and competes for the active site of the enzyme are known as competitive inhibitors. Usually such inhibitors show a close structural resemblance to the substrates to the enzyme they inhibit. In such a case, inspite of enzyme substrate complex, enzyme inhibitor complex is formed and enzyme activity is inhibited.

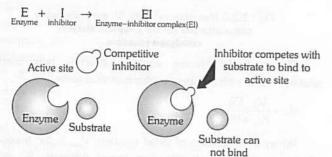

Fig: 3.2-3 Competitive inhibition

The concentration of EI complex depends on the concentration of free inhibitor. Because EI complex readily dissociates, the empty active sites are then available for substrate binding. The effect of a competitive inhibitor on activity is reversed by increasing the concentration of substrate. In it V_{max} remain constant and Km increases.

A classic example of competitive inhibition is succinic acid dehydrogenase which oxidises succinic acid to fumaric acid. If concentration of malonic acid, is added, the activity of succinic dehydrogenase decreases rapidly. Hence malonic acid acts as a competitive inhibitor since it has structural resemblance to succinic acid.

The competitive inhibition can be reversed by increasing the concentration of the substrate. Competitive inhibitors are used in control of bacterial pathogens.

Non-competitive inhibition : These substances (poisons) do not combine with active sites but attach somewhere else and destroy the activity of enzyme.

Both EI and ES complexes are formed. Inhibitor binding alters the three dimensional configuration of the enzyme and thus blocks the reaction. Non competitive inhibitor do not competes directly with the substrate for binding to the enzyme. In it V_{\max} in lowered and Km is changed.

The non-competitive inhibition can not be reversed by increasing the concentration of the substrate *i.e.*, irreversible. *e.g.*, cyanide inhibits the mitochondrial enzyme cytochrome oxidase which is essential for cellular respiration. This kills the animals.

More AMP is a non competitive inhibitor of fructose biphosphate phosphatase, the enzyme that catalyzes the conversion of fructose 1, 6 biphosphate to fructose 6 phosphate.

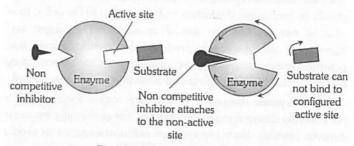

Fig: 3.2-4 Non-competitive inhibition

Feedback inhibition: In number of cases, accumulation of the final product of the reaction is capable of inhibiting the first step of reaction.

$$A \xrightarrow{E_1} B \xrightarrow{E_2} C \xrightarrow{E_3} D \xrightarrow{E_4} P$$

The product P checks the activity of enzyme which converts A into B. It is quite useful mechanism because it checks the accumulation of products.

The phenomenon in which the end product of a metabolic pathway can regulate its own production by inhibition of the sort is called **feed back inhibition** or negative feed back inhibition. This type of inhibition can be shown in *Escherichia coli* bacterium which synthesises the amino acid isoleucine from a substrate threonine by a series of intermediate reactions (i.e., α ketobutyrate threonine deaminase, α Aceto hydroxy butyrate, α keto β methyl valerate etc).

When isoleucine accumulates in amounts more than required, it stops its own production by inhibiting the activity of the enzyme. Threonine deaminase which catalyzes the first reaction of the series. This type of metabolic control in which the first enzyme of a series is inhibited by the end product, is known as end product inhibition.

Allosteric inhibition (Modulation): Allosteric literally means 'another place'. Still other inhibitors join an enzyme at a specific site and change the form of the active site meant for the substrate. These inhibitors are known as modifiers or modulators and the sites where they fit in are called allosteric sites. Modulators are of two types-positive (activators) and negative (inhibitors).

Change of active site which prevent the binding of substrate to the enzyme and stops the reaction. The process is called allostery or allosteric inhibition, The enzyme with allosteric sites are called allosteric enzymes. Jacob and Monod have termed this phenomenon as allosteric transition.

An example of allosteric enzyme inhibition is hexokinase that converts glucose to glucose 6-phosphate. Glucose 6-phosphate causes allosteric inhibition of hexokinase. This is called feedback allosteric inhibition.

Some terms regarding enzymes

Zymogens or (Enzyme Precursors): Certain enzymes are produced by the living cells in an inactive (non-functional) form. They are called the zymogens or proenzymes. It is then converted, usually by proteolysis (hydrolysis of the protein), to the active form when it has reached the site of its activity. Pepsinogen and trypsinogen are zymogens produced by gastric glands and pancreas respectively. They are necessary to life because they degrade dietary proteins into amino acids that are used by the cell.

Isoenzymes (Isozymes): There are certain enzymes which have slightly different molecular structure but performing the same catalytic function. Such enzymes are called isoenzymes or simply isozymes. Isoenzyme of an enzyme differ from each another in their amino acid sequence, molecular weight, immunological and electrophoretic behaviours. Hence, they can be separated by electrophoresis.

More than 100 enzymes are known to have isoenzyme. A good example of isoenzyme is lactic dehydrogenase (LDH). It catalyzes change of pyruvate to lactate.

Inducible enzymes : An enzyme which is synthesized only in the presence of its substrate (inducer) is called inducible enzyme e.g., β -galactosidase.

Constitutive enzymes (House keeping enzyme): The enzyme which are found in constant amounts under different growth conditions (regardless of its metabolic states) are called constitutive enzyme e.g., enzymes of sugar breakdown i.e., glycolysis.

Repressible enzymes: The presence of a specific substance may inhibit continued production of specific enzyme (enzyme repressor) *e.g.*, glucokinase.

Ribozymes: Study of post transcriptional processing of RNA molecules has led to the most exciting discovery of the existence of some catalytic RNA molecules which have been called as RNA enzymes or ribozymes. All enzymes are not proteins as confirmed by Cech (1981) and Altman (1983). Ribozyme and RNAase-P are two non protein enzyme where RNA acts as catalyst. Ribozyme was reported from Tetrahymens (a protozoans) by Cech. The substrate for ribozyme is usually an RNA molecule. RNAase-P (Ribonuclease) was discovered by Altman.

Peptidyl transferase is also a non-proteinaceous enzyme, discovered by Noller.

Michaelis constant : Michaelis and Menten (1913) introduced a constant K_m (Michaelis constant).

It is a mathematical derivative or constant which indicates the substrate concentration at which the chemical reaction catalysed by an enzyme attains half its maximum velocity $(V_{\rm max})$.

K_m indicates affinity of the enzyme for its substrate.

$$K_m = \frac{1}{2}V_{\text{max}}$$

 $K_{\rm m}$ value differs from substrate to substrate because different enzymes differ in their affinity towards different substrates. A high $K_{\rm m}$ indicates low affinity while a low $K_{\rm m}$ shows strong affinity. Protease acts on different proteins. So it's $K_{\rm m}$ value will differ from protein to protein.

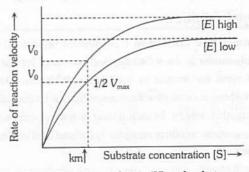

Fig: 3.2-5 Reaction velocity 'V' and substance concentration (S) for a typical enzyme catalysed reaction

The Michaelis Menten equation describe how reaction relatively varies with substrate concentration as given

$$V_0 = \frac{V_{\text{max}}[S]}{K_m + [S]}$$

Where V_0 is the rate of initial reaction; V_{max} is the maximum relative or the reaction rate with excess substrate; K_{m} is the Michaelis constant $=K_2+K_3/K_1$; [S] is the substrate concentration.

UNIVERSAL BOOK DEPOT 1960

The above reaction shows that the greater the affinity between an enzyme and its substrate, the lower the $K_{\rm m}$ (in units moles per litre) of the enzyme substrate reaction. Stated inversely, $1/K_{\rm m}$ is the measure of affinity of the enzyme for its substrate.

Enzyme-inhibitor dissociation constant (Ki): It is dissociation constant of enzyme – inhibitor complex.

$$Ki = \frac{[E][I]}{[EI]}$$

Where, E is enzyme and I is concentration of inhibitor.

High Ki decreases enzyme activity while low Ki increases some, it is applicable to competitive inhibitors.

Factors affecting the enzyme activity

Substrate concentration: If there are more enzyme molecules than substrate molecules, a progressive increase in the substrate molecules increases the velocity of their conversion to products. However, eventually the rate of reaction reaches the maximum. At this stage the active sites of all the available enzyme molecules are occupied by the substrate molecules. Therefore, the substrate molecules occupy the active sites vacated by the products and cannot increase the rate of reaction further.

Enzyme concentration : The rate of reaction is directly proportional to enzyme concentration. An increase in enzyme concentration will cause a rise in the rate of reaction upto a point and them the rate of reaction will be constant. Increasing the enzyme concentration increases the number of available active sites.

Product concentration: Accumulation of the product of enzyme reaction lowers the enzyme activity. Enzyme molecules must be freed to combine with more substrate molecules. Normally the product are quickly removed from the site of formation and the reaction does not suffer.

Hydrogen ion concentration (pH): Some enzyme act best in an acid medium, other in an alkaline medium, for every enzyme there is an optimum pH where its action is maximum e.g., 2 for pepsin, 6.8 for salivary amylase, 8.5 for trypsin. Most enzyme show maximum activity in a pH range of about 6.0 to 7.5 *i.e.*, near neutral pH (endoenzymes). A shift to the alkaline or acid side rapidly decreases the enzyme activity and finally stops it altogether. This is due to denaturation of enzyme molecule i.e., change in its physical structure.

Temperature: Within certain limits (5-40°C) the rate of an enzyme catalyzed reaction increases as the temperature increases. The Q_{10} of most enzymatic reactions is 2, i.e., every $10^{\circ}C$ rise in temperature doubles the rate of reaction. Most enzymes show maximum activity in a temperature range of 25 to 40°C. Beyond this temperature, there is sharp fall in the rate of reaction. Above $50^{\circ}C$ they get denatured completely.

Modification in the physical form of the enzyme results in the loss of its catalytic activity. This change in structure is called **denaturation** of protein. This is the permanent change, and the denatured enzyme protein remains inactive even if the temperature is then brought down. The enzymes are not destroyed by freezing, and regain their lost activity if the temperature is raised to normal.

Deep freezing of food for preserving them for long periods is done not only to prevent the growth and multiplication of microorganisms but also to inactivate enzymes. It makes impossible for the microorganisms to digest the food. Below freezing point enzymes become inactive but do not get denatured.

Enzyme inhibitors: Certain chemical compounds inhibit activity of enzyme molecules either permanently or temporarily. Thus, diisopropyl flurophosphate (DFP) inhibits the action of various enzymes catalysing hydrolysis of ester linkage. Inhibition is permanent or irreversible.

Poisons and Radiation : Poisons such as cyanide and radiation destroy the tertiary structure of the enzymes, making them ineffective.

- Most of the vitamins of B complex group act as coenzyme.
- Myosin a structural component of muscle. It has ATPase activity also.
- Synthesis of enzymes occur in polysome (aggregation of ribosomes).
- CAMP mediated cascade model of enzyme regulation was proposed by Sutherland.
- $\operatorname{\text{\fontfamily{180}}}$ Competitive inhibitor increase Michaelis constant (K_m) but it has no effect on V_{max}
- Regulators of metabolism are enzymes, vitamins and hormones.
- RNA polymerase enzyme form RNA from DNA and DNA polymerase is responsible for synthesis of DNA from DNA.
- Enzyme that catalyses the conversion of soluble proteins into insoluble ones, process is called enzyme coagulation.
- Albinism is caused by the deficiency of tyrosinase.
- Iron porphyrin coenzyme or cofactor is cytochrome.
- Nitrogenase enzyme is inactivated by oxygen.
- Nitrogenase enzyme is responsible for the reduction of molecular nitrogen to the level of ammonia in leguminous root nodule.
- $\operatorname{\mathscr{E}}$ Nitrate reductase enzyme is responsible for the formation of NO_2 .
- Amylopsin acts upon polysaccharide in alkaline medium.
- Due to enzymatic transformations huge amount of starch is deposited in potato tubers.
- \mathcal{L} Tertiary structure of protein component of enzyme is destroyed by a number of factors like heat, high energy radiation and salts of heavy metals (e.g., Ag^+ , Hg^{2+} , As^+ .)
- Some enzyme are active at very high temperature (70–80°C) called extermozyme e.g., Taqe polymerase.
- Smallest enzyme is peroxidase and largest being catalase found in peroxisome.

Objective Questions

Carbohydrates, Starch and Protein

- Starch and cellulose are the compounds made up of many units of [CPMT 1993, 2003, 09]
 - (a) Simple sugar
- (b) Fatty acid
- (c) Glycerol
- (d) Amino acid
- Which one of the following is the sweetest sugar or laevorotatory sugar [AFMC 2002; MP PMT 2007]

Or

Inulin is a polymer of

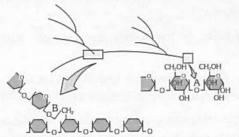

[WB JEE 2011]

- (a) Fructose
- (b) Glucose
- (c) Galactose
- (d) Sucrose
- 3. Which of the following is the characteristic of plants

[MP PMT 2003]

[NCERT]

- (a) Glucose and cellulose
- (b) Pyruvic acid and glucose
- (c) Cellulose and starch
- (d) Starch and pyruvic acid
- Observe the following figure and identify A and B bonds in the diagrammatic representation of a portion of glycogen

- (a) A = 1-4 α glycosidic bonds , B = 1-4 α glycosidic bonds
- (b) A = 1-1 α glycosidic bonds , B = 1 1 α glycosidic bonds
- (c) A = 1-6 α glycosidic bonds , B = 1 4 α glycosidic bonds
- (d) A = 1-4 α glycosidic bonds , B = 1 6 α glycosidic bonds
- 5. Inulin found in plant cell is a

[Odisha PMT 2002; WB JEE 2012; AIIMS 2012]

- (a) Lipid
- (b) Protein
- (c) Polysaccharide
- (d) Vitamin
- Pentoses and hexoses are the most common [BHU 2002]

Or

The simple polyhydroxy ketone molecule containing 3–7 carbons is a [Kerala PMT 2006]

- (a) Disaccharides
- (b) Monosaccharides
- (c) Oligosaccharides
- (d) Polysaccharides
- Corn is immersed in the boiling water. It is then cooled, the solution becomes sweet. It is due to

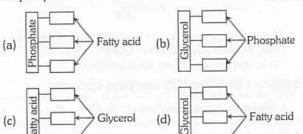

[AFMC 1999; JIPMER 2001]

- (a) Enzymes are inactivated in boiling water
- (b) Disaccharides are converted to monosaccharides
- (c) Monosaccharides are converted to disaccharides
- (d) None of these

8. Cholesterol belongs to which of the following groups

[Odisha JEE 2008; J & K CET 2012]

- (a) Steroids
- (b) Neutral fats
- (c) Waxes
- (d) Phospholipids
- Which one of the following diagrams shows a molecule of simple lipid [NCERT]

- The alpha helices and beta sheets are the example of which level of protein organization [J & K CET 2012]
 - (a) Primary structure
- (b) Secondary structure
- (c) Tertiary structure
- (d) Quaternary structure
- 11. Sucrose, a common table sugar, is composed of

[Odisha JEE 2004; CPMT 2009]

- (a) Glucose + fructose
- (b) Glucose + galactose
- (c) Fructose + galactose
- (d) None of these
- Which is non-reducing sugar

[Odisha JEE 2004; Bihar CECE 2005; CBSE PMT 2014]

- (a) Glucose
- (b) Galactose
- (c) Mannose
- (d) Sucrose
- 13. Sugar and amino acids are
- [MHCET 2004]
- (a) Primary metabolites
- (b) Secondary metabolites
- (c) Feed stock
- (d) Inoculum
- A complex polysaccharide produced from sucrose by the bacterium Leuconostoc mesenteroides is [BHU 2004]
 - (a) Chitin
- (b) Starch
- (c) Cellulose
- (d) Dextran
- 15. The chemical formula of starch is
- h is [RPMT 2002]
 - (a) $(C_6H_{10}O_5)_n$
- (b) $(C_6H_{12}O_6)_n$
- (c) C₁₂H₂₂O₁₁
- (d) CH3COOH
- 16. Oval shaped and eccentric starch particles are found in

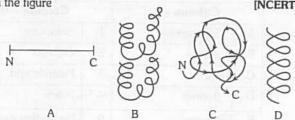

[RPMT 1995]

- (a) Wheat
- (b) Maize
- (c) Potato
- (d) Rice
- 17. Which one of the following
- . conjugate protein
- THE REAL PROPERTY OF
- [Odisha PMT 2002]
- (a) Globulin
- (b) Albumin
- (c) Histone
- (d) Flavoprotein
- 18. Glycoproteins contain

[KCET 2000]

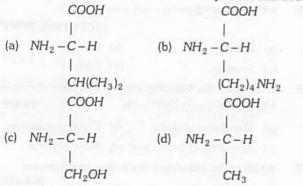

- (a) Protein and fat
- (b) Protein and salt
- (c) Protein and vitamin
- (d) Protein and carbohydrates

See the following figure and identify the structure of proteins in the figure

- (a) A = 4° structure, B = 3° structure, C = 2° structure, D
- (b) A = 1° structure, B = 4° structure, C = 3° structure, D =2° structure
- (c) $A = 4^{\circ}$ structure, $B = 2^{\circ}$ structure, $C = 3^{\circ}$ structure, D = 1° structure
- (d) A=1° structure, B = 2° structure, C = 3° structure, D = 4º structure
- Which one of the following is a basic amino acid

[Odisha JEE 2012]

Largest physical and chemical molecules are

[CBSE PMT 1996]

Or

What are the most diversed molecules in the cell

[MP PMT 2000]

No cell could live without

[MP PMT 1997]

- (a) Carbohydrates
- (b) Lipids
- (c) Proteins
- (d) Nucleic acids
- 22. Find out the wrongly matched pair [Kerala PMT 2010]
 - (a) Primary metabolite
- Ribose
- (b) Secondary metabolite
- Anthocyanins
- (c) Protein
- (d) Chitin
- Insulin
- Polysaccharide
- (e) Cellulose
- Heteropolymer
- 23. Lipids are insoluble in water, because lipids molecules are
 - [CBSE PMT 2002]

- (a) Neutral
- (b) Zwitter ions
- (c) Hydrophobic
- (d) Hydrophilic
- 24. Which one of the following statements is wrong
 - [NEET (Phase-I) 2016]
 - (a) Sucrose is a disaccharide
 - (b) Cellulose is a polysaccharide
 - (c) Uracil is a pyrimidine
 - (d) Glycine is a sulphur containing amino acid
- Which of the following is conjugated protein [MHCET 2000]
 - (a) Chromoproteins
- (b) Phosphoprotein
- (c) Glycoprotein
- (d) All of the above

α-helical model of protein was discovered by

[BVP 2000; MHCET 2001]

- (a) Pauling and Correy
- (b) Watson
- (c) Morgan
- (d) Berzelus
- Which one of the following biomolecules is correctly 27. characterised [NCERT; CBSE PMT (Mains) 2012]
 - (a) Lecithin a phosphorylated glyceride found in cell membrane
 - (b) Palmitic acid an unsaturated fatty acid with 18 carbon
 - (c) Adenylic acid adenosine with a glucose phosphate molecule
 - (d) Alanine amino acid Contains an amino group and an acidic group anywhere in the molecule
- 28. High content of lysine is present in [MHCET 20031
 - (a) Wheat
- (b) Apple
- (c) Maize
- (d) Banana
- 29. Example of a typical homopolysaccharide is [WB JEE 2011]
 - (a) Lignin
- (b) Suberin
- (c) Inulin
- (d) Starch
- 30. Arachidonic acid is
- [MHCET 2003]
- (a) Non-essential fatty acid (b) Essential fatty acid
- (c) Polyunsaturated fatty acid (d) Both (b) and (c)
- 31. The two polypeptides of human insulin are linked together [NEET (Phase-I) 2016]
 - (a) Hydrogen bonds
- (b) Phosphodiester bond
- (c) Covalent bond
- (d) Disulphide bridges
- Which of the following carbon is anomeric in glucose
- - [BHU 2012]

- (a) C₁
- (b) C2
- (c) C4
- (d) None of these
- During strenous exercise glucose is converted into [BHU 2005]
 - (a) Glycogen
- (b) Pyruvic acid
- (c) Starch
- (d) Lactic acid
- 34. In which form does the food transported in plants [BHU 2005]
 - (a) Sucrose
- (b) Fructose
- (c) Glucose

- (d) Lactose
- 35. Which of the following fatty acids is liquid at room temperature [NCERT; AMU (Med.) 2012]
 - (a) Palmitic acid
- (b) Stearic acid
- (c) Oleic acid
- (d) Linoleic acid
- 36. Match the following and choose the correct combination from the options given

Column I (Organic Compound)

Column II (Example)

- A. Fatty acid
- Glutamic acid
- B. Phospholipid
- 2. Tryptophan
- Aromatic amino acid
- 3. Lecithin
- D. Acidic amino acid
- 4. Palmitic acid
- [NCERT; Kerala PMT 2012] (b) A-4, B-3, C-2, D-1
- (a) A-1, B-2, C-3, D-4 (c) A-2, B-3, C-4, D-1
- (d) A-3, B-4, C-1, D-2
- (e) A-4, B-3, C-1, D-2

- 37. Which of the following amino acids is not optically active
 - (a) Glycine
- (b) Valine
- (c) Leucine
- (d) Isoleucine
- 38. Paraffin wax is
- /1.\ A . 1
- (a) Ester
- (b) Acid
- (c) Monohydric alcohol
- (d) Cholesterol

[BHU 2006]

 Match the items in column I with those in column II and choose the correct answer

	Column I		Column II
	(Biomolecules)		(Examples)
A.	Carbohydrates	1.	Trypsin
B.	Protein	2.	Cholesterol
C.	Nucleic acid	3.	Insulin
D.	Lipid	4.	Adenulic acid

[Kerala PMT 2012]

- (a) A-3, B-1, C-4, D-2 (c) A-3, B-4, C-1, D-2
- (b) A-2, B-3, C-4, D-1
- (e) A-1, B-2, C-3, D-4
- (d) A-4, B-1, C-2, D-3
- 40. Match the items in column I with items in column II and choose the correct answer

	Column I		Column II
A.	Triglyceride	1.	Animal hormones
B.	Membrane lipid	2.	Feathers and leaves
C.	Steroid	3.	Phospolipids
D.	Wax	4.	Fat stored in form of droplets

[Kerala PMT 2006]

- (a) A-4, B-3, C-1, D-2
- (b) A-2, B-3, C-4, D-1
- (c) A-3, B-4, C-1, D-2
- (d) A-4, B-1, C-2, D-3
- (e) A-4, B-3, C-2, D-1
- 41. Given below is the chemical formula of

[NCERT; Kerala PMT 2007]

- (a) Palmitic acid
- (b) Stearic acid
- (c) Glycerol
- (d) Galactose
- (e) Fumaric acid
- 42. Find out the mis-matched pair

[Kerala PMT 2007]

(a) Agar

Polymer of glucose and sulphur containing carbohydrates

- (b) Chitin
- Polymer of glucosamine
- (c) Peptidoglycan
- Polysaccharide linked to peptides
- (d) Lipopolysaccharides
- A complex of lipid and polysaccharide
- (e) Glycogen
- Polymer of glucose
- 43. Select the wrong statement
- [Kerala PMT 2007]
- (a) The building blocks of lipids are amino acids
- (b) Majority of enzymes contain a non-protein part called the prosthetic group
- (c) The thylakoids are arranged one above the other like a stack of coins forming a granum
- (d) Crossing-over occurs at pachytene stage of meiosis I
- (e) Steroids are complex compounds commonly found in cell membranes and animal hormones

44. Match the following with correct combination

	Column – I	Column – II		
A.	Triglycerides	1.	Galactose	
B.	Lactose	2.	Glycerol	
C.	RNA	3.	Palmitic acid	
D.	β pleats	4.	Uracil	
E.	Beewax	5.	Secondary structure	

[Kerala PMT 2007]

- (a) A-4, B-1, C-5, D-2, E-3
- (b) A-5, B-1, C-4, D-2, E-3
- (c) A-3, B-1, C-4, D-5, E-2
- (d) A-2, B-1, C-4, D-5, E-3
- (e) A-3, B-1, C-4, D-2, E-5
- Which of the following is not a disaccharide

[KCET 1999; DPMT 2007]

- (a) Maltose
- (b) Starch
- (c) Sucrose
- (d) Lactose
- 46. What does the following equation denote? Amino acid + ATP → Aminoacyl AMP + PP [DPMT 2007]
 - (a) Elongation of chain
- (b) Chain termination
- (c) Activation of amino acid (d) None of these
- 47. Which of the following is not a conjugated protein
 - [WB JEE 2010]
 - (a) Peptone
- (b) Phosphoprotein
- (c) Lipoprotein
- (d) Chromoprotein
- 48. Which of the following fats is least harmful for heart

[DPMT 2007]

- (a) Saturated fat
- (b) Cholesterol
- (c) Polyunsaturated fat
- (d) Oils
- Protein denaturation takes place by the activity of
 - [Odisha JEE 2008]

[MP PMT 1999]

Or

Enzymes are sensitive to (a) Water

(b) Heat

(c) Enzyme

- (d) Pressure
- In a polysaccharide, the individual monosaccharides are linked by a [AMU (Med.) 2011; Kerala PMT 2011]
 - (a) Glycosidic bond
- (b) Peptide bond
- (c) Ester bond
- (d) Phosphodiester bond
- (e) Hydrogen bond
- **51.** Select the incorrect statement

[Kerala PMT 2011]

- (a) Amino acids are substituent methanes
 - (b) Glycerol is a trihydroxy propane
- (c) Lysine is a neutral amino acid
- (d) Lecithin is a phospholipid
- (e) Adenosine is a nucleoside

NIVERSA! OOK DEPOT 196

- 52. Carbohydrates are commonly found as starch in plant storage organs. Which of the following five properties of starch (A-E) make it useful as a storage material
 - (A) Easily translocated
 - (B) Chemically non-reactive
 - (C) Easily digested by animals
 - (D) Osmotically inactive
 - (E) Synthesized during photosynthesis

The useful proeprties are:

[CBSE PMT 2008]

- (a) (A), (C) and (E)
- (b) (A) and (E)
- (c) (B) and (C)
- (d) (B) and (D)
- Which of the following promotes softening of fruits 53.

[Kerala PMT 2008]

- (a) Polygalacturonase
- (b) Colchicine
- (c) Polyethylene glycol
- (d) Cellulase
- (e) Brazzein
- 54. Which of the following statements is/are not true
 - (A) Glycerol is a 3 carbon alcohol with 3 OH groups that serve as binding sites
 - (B) Waxes are esters formed between a long chain alcohol and saturated fatty acids
 - (C) The term protein was coined by Gerardus Johannes
 - (D) Agar is an indispensable polysaccharide and it is a complex polymer of glucose and sulphur-containing carbohydrates

[Kerala PMT 2008]

- (a) (A) and (C) only
- (b) (A) and (D) only
- (c) (A), (B) and (D) only
- (d) (A), (C) and (D) only
- (e) (D) only
- Which is an organic compound found in most cells 55.

[DUMET 2009]

Most common monomer of carbohydrate is

[Odisha JEE 2008]

The "repeating unit" of glycogen is

[WB JEE 2009]

- (a) Glucose
- (b) Water
- (c) Sodium chloride
- (d) Oxygen
- 56. Quarternary structure of protein
- [NCERT; WB JEE 2008]
 - (a) Consists of four subunits
 - (b) May be either α or β
 - (c) Is unrelated to two function of the protein
 - (d) Is dictated by the primary structures of the individual subunits
- 57. Which of the following carbohydrates is not a disaccharide

[WB JEE 2008]

- (a) Maltose
- (b) Lactose
- (c) Sucrose Chitin is a

58.

- (d) Galactose
- [WB JEE 2010; NEET 2013]
- (a) Polysaccharide
- (b) Nitrogenous polysaccharide
- (c) Lipoprotein
- (d) Protein

59. Which of the following is the least likely to be involved in stabilizing the three-dimensional folding of most proteins

[NEET (Phase-II) 2016]

- (a) Ester bonds
- (b) Hydrogen bonds
- (c) Electrostatic interaction
- (d) Hydrophobic interaction
- Which of the followings can bring about the denaturation of 60. proteins [WB JEE 2016]
 - (a) Reaction to salts of heavy metals
 - Reaction to acid and bases
 - Reaction to inorganic neutral salts
 - (d) Preservation at a temperature below-5°C

Nucleotides and Nucleic acid

A ribose (but not deoxyribose) nucleotide is

[Kerala PMT 2004]

- (a) Cytosine pentose sugar phosphate
- (b) Guanine pentose sugar phosphate
- (c) Thymine pentose sugar phosphate
- (d) Uracil pentose sugar phosphate
- DNA is present in [NCERT; MP PMT 1995, 96, 98: BVP 2000; RPMT 2001; MHCET 2001; AIIMS 2004]

Or

Which one of the following has its own DNA

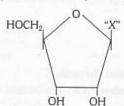

[CBSE PMT (Pre.) 2010]

- (a) Nucleus only
- (b) Mitochondrion only
- (c) Chloroplast only
- (d) All the above
- 3. See the following figure and identify the correct combination

[NCERT] Adenine HOCH Adenine он он OH OH

B A B C (a) Uracil Adenosine Adenylic acid (Nucleoside) (Nucleotide) (b) Adenosine Adenylic acid Adenine (Nucleoside) (Nucleotide) (N - base) (c) Adenine Adenosine Adenylic acid (N - base)(Nucleoside) (Nucleotide) (d) Adenine Adenosine Adenylic acid (N - base) (Nucleotide) (Nucleoside)

Given below is the diagrammatic representation of one of the categories of small molecular weight organic compounds in the living tissues. Identify the category shown and the one blank component "X" in it [NCERT; CBSE PMT (Pre.) 2012]

Category	Component
Cholesterol	Guanin

- (b) Amino acid
- Guanin NH_2
- Nucleotide (c)

(a)

- Adenine
- (d) Nucleoside
- Uracil

	EPOT 1960	548 Biomolecul

(d) Mitochondria and chloroplast

(a) Thymine

(c) Guanine

(a) Mitochondria

(c) Bacteriophage

15.

Which of the following is not a pyrimidine

16. DNA is not present in one of the following [MP PMT 2003]

(b) Uracil

(d) Cytosine

(b) Chloroplast

(d) Tobacco mosaic virus

17. DNA strands are antiparallel because of the presence of [Kerala PMT 2004] (a) H-bonds (b) Peptide bonds (c) Disulphide bonds (d) Phosphate-diester bonds (e) None of the above Examine the following figures and select the right answer in which diagrammatic representation of a nucleotide is [NCERT] correctly shown NH. HO-P-OCH ÓН (a) OH OH HOCH N-base (c) (d) HO-P-O N-base OH OH OH Which of the following bases is present in RNA in place of 19. [NCERT; CPMT 1996, 2003; MP PMT 1998, 2001, 10; Pb PMT 2000; Odisha JEE 2004; J & K CET 2005, 08; Kerala PMT 2009, 11] (a) Uracil (b) Adenine (c) Guanine (d) Water 20. Nucleic acids were discovered by [MP PMT 1999] DNA was first discovered by [CPMT 1994] (a) Watson and Crick (b) Khorana (c) Wilkins (d) Miescher 21. In DNA molecule, which of the following base pair is present [MP PMT 1992] (a) Cytosine and adenine (b) Adenine and thymine (c) Adenine and guanine (d) Cytosine and thymine 22. The given diagram shows the nitrogenous bases. Identify the correct combination [NCERT] NH. B (a) A = Guanine; B = Uracil (b) A= Adenine; B= Uracil

> (c) A = Guanine; B = Thymine (d) A = Adenine; B= Thymine

(a) DNA can duplicate itself

(d) None of these

(a) $A \equiv T$ and C = G

(c) A = T and $C \equiv G$

(b) RNA is the genetic material

(c) DNA is the genetic material

The base pairs of DNA are correctly shown as

The transformation experiments on Pneumococcus showed

[Bihar MDAT 1995; RPMT 1997; BHU 1998, 99, 2004;

BVP 2000; MHCET 2003; MP PMT 2013]

(b) A = T and C = G

(d) $A \equiv T$ and $C \equiv G$

23.

24.

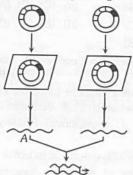

[MP PMT 2007]

that

20	*****					RUMINIOS TRANSPORTED
25.	Which one of the follow	ving is widely distributed in a cell	3.	Enzymes are basically or	All enzymes contain	[NCERT:
		[MHCET 2000]		MP PMT 1	995, 2000, 04, 05; CBS	E PMT 2000;
	(a) DNA	(b) RNA		BVP 200	2; MHCET 2003; Odish	a JEE 2009]
	(c) Chloroplast	(d) Chromoplast		(a) Sugars	(b) Proteins	
26.	Which of the cell organ	nelles are devoid of deoxy ribonucleic		(c) Fats	(d) Vitamins	
	acid	iches are devoid of deoxy hoofidciele	4.	"Enzymes are proteins", i	t was suggested by	

- acid [RPMT 1997]
 - (a) Mitochondria and nucleus
 - (b) Chloroplast and mitochondria
 - (c) Nucleus and chloroplast
 - (d) Lysosome and dictyosome
- 27. The similarity between DNA and RNA is that both are [KCET 1999, 2006]
 - (a) Double stranded
 - (b) Having similar sugars
 - (c) Polymers of nucleotides
 - (d) Having similar pyrimidines

28. What indicated "A" in given figure

- (a) Peptide bond
- (b) Glycosidic bond
- (c) Disulfide bond
- (d) Hydrophobic bond
- 29. Which of the following biomolecules does have phosphodiester bond [AIPMT 2015]
 - (a) Monosaccharides in a polysaccharide
 - (b) Amino acids in a polypeptide
 - (c) Nucleic acids in a nucleotide
 - (d) Fatty acids in a diglyceride
- 30. Ultraviolet light absorbed by nucleic acid is [RPMT 2000]
 - (a) 26 nm
- (b) 75 nm
- (c) 260 nm
- (d) 1500 nm
- 31. The length of DNA having 23 base pairs is

[Kerala PMT 2004; WB JEE 2009]

- (a) 70 Å
- (b) 78.4 Å
- (c) 78.2 Å
- (d) 74.8 Å
- (e) 74.2 Å

Introduction, properties, action and inhibition of enzyme

- Who first used the term "enzyme" [CPMT 2004]
 - (a) J.B. Sumner
- (b) Kuhne
- (c) Thompson
- (d) Garnier
- Who coined the term zymase for enzymes in yeast
- (b) Sumner
- (c) Louis pasteur
- (d) Edward Buchner

[BHU 2002]

- (a) Miller
- (b) Sumner
- (c) Pasteur
- (d) Leeuwenhock
- 5. Who got the Nobel prize working on enzymes in the year 1978

[MP PMT 1997]

[BHU 2001]

- (a) W. Arber and D. Nathans
- (b) Nass and Nass
- (c) R. Misra
- (d) H.G. Khorana
- 6. To explain the mechanism of enzymatic action, who proposed "Lock and key hypothesis"

MP PMT 1998, 2010, 12; BHU 2000; RPMT 2002]

- (a) Fischer
- (b) Jacob
- (c) Koshland
- (d) Sumner
- Many of the hydrolytic reactions are
 - (a) Reversible
- (b) Irreversible
- (c) Endothermic
- (d) Exothermic
- The "lock and key" model of enzyme action illustrates that a particular enzyme molecule [DUMET 2009, 10]
 - (a) May be destroyed and resynthesized several times
 - (b) Interacts with a specific type of substrate molecule
 - Reacts at identical rates under all conditions
 - (d) Forms a permanent enzyme-substrate complex
- Enzymes were discovered for the first time in [Pb. PMT 1995]
 - (a) Yeast
- (b) Maize
- (c) Bacteria
- (d) Algae
- Who discovered 'co-enzymes'
 - (a) James Sumner
- (b) Fritz Lipmann
- (c) Mayerhoff
- (d) Edward Buchner
- A competitive inhibitor of succinic dehydrogenase is

[NCERT; CBSE PMT 2008]

[BHU 1998]

- (a) α-ketoglutarate
- (b) Malate
- (c) Malonate
- (d) Oxaloacetate
- An example of feedback inhibition is
 - [Kerala PMT 2008]
 - (a) Cyanide action on cytochrome
 - (b) Sulpha drug on folic acid synthesizer bacteria
 - (c) Allosteric inhibition of hexokinase by glucose 6phosphate
 - (d) Reaction between succinic dehydrogenase and succinate
 - (e) The inhibition of succinic dehydrogenase by malonate
- Who proposed the principal of "Induced fit" 13.
 - (a) Jacob
- (b) Fischer
- (c) Koshland
- (d) Laderberg
- 14. The molecules that are well recognized as biocatalysts in addition to enzymes are [AFMC 2012]
 - (a) Polysaccharides
- (b) Fatty acids
- (c) RNAs
- (d) None of these

(d) Non-competitive inhibitors often bind to the enzyme

irreversibly

In which one of the following enzymes, is copper necessarily [MP PMT 1994] 23. 15. Enzymes are the polymers of [CBSE PMT 2004] associated as an activator (a) Lactic dehydrogenase (b) Tyrosinase Which of the following is polymerized to form proteins (d) Tryptophanase [MHCET 2003] (c) Carbonic anhydrase Or 24. Km is related to [BHU 2000] An enzyme can be synthesised by chemically bonding (b) ABO blood group (a) Morphology [AFMC 1994] together molecules of (d) Chromatography (c) ES complex (b) Fatty acids (a) Hexose carbon Arrange the steps of catalytic action of an enzyme in order 25. (c) Amino acids (d) Inorganic phosphate an choose the right option [AIIMS 2005] 16. Telomerase is an enzyme which is a (A) The enzyme releases the products of the reaction and the (a) Simple protein (b) RNA enzyme is free to bind to another substrate (d) Repetitive DNA (c) Ribonucleoprotein (B) The active site of enzyme is in close proximity of the 17. Which one of the following statements is incorrect substrate and breaks the chemical bonds of the substrate [AIPMT (Cancelled) 2015] (a) In competitive inhibition, the inhibitor molecule is not (C) The binding of substrate induces the enzyme to alter its chemically changed by the enzyme shape fitting more tightly around the substrate (b) The competitive inhibitor does not affect the rate of (D) The substrate binds to the active site of the enzyme fitting breakdown of the enzyme-substrate complex [Kerala PMT 2010] into the active site (c) The presence of the competitive inhibitor decreases the (b) (C), (B), (A), (D) (a) (D), (C), (B), (A) Km of the enzyme for the substrate (c) (D), (B), (A), (C) (d) (B), (A), (D), (C) (d) A competitive inhibitor reacts reversibly with the enzyme to form an enzyme-inhibitor complex (e) (C), (D), (A), (B) An example of non-competitive inhibition is 18. 26. Select the option which is not correct with respect to enzyme [Kerala PMT 2009] [CBSE PMT 2014] (a) The inhibition of succinic dehydrogenase by malonate (a) A non-competitive inhibitor binds the enzyme at a site (b) Cyanide action on cytochrome oxidase distinct from that which binds the substrate (c) Sulpha drug on folic acid synthesizing bacteria (b) Malonate is a competitive inhibitor of succinic (d) The inhibition of hexokinase by glucose 6-phosphate dehydrogenase (e) Reaction of succinic dehydrogenase (c) Substrate binds with enzyme at its active site [CBSE PMT 2000; AFMC 2003] 19. Enzymes are absent in (d) Addition of lot of succinate does not reverse the (a) Algae (b) Fungi inhibition of succinic dehydrogenase by malonate (d) Virus (c) Bacteria Inhibition of acetylcholine by DEP (Diisorpropyl-27. Feedback inhibition of enzymes is affected by which of the 20. [AMU (Med.) 2012] fluorophosphate) is an example of [WB JEE 2009] following (a) Competitive inhibition (b) Non-competitive inhibition Jacob and Monad named those enzymes allosteric whose (c) Non-competitive irreversible inhibition activity is regulated by (d) Allosteric inhibition (b) Substrate (a) Enzyme The catalytic efficiency of two different enzymes can be 28. (c) End products (d) Intermediate end products compared by the [CBSE PMT 2005] Non-proteinaceous enzyme that acts as a catalyst for the (a) Formation of the product formation of peptide bond is [MHCET 2000; MP PMT 2007; (b) The pH of optimum value AMU (Med.) 2010; NEET (Phase-II) 2016] (c) The Km value (d) Molecular size of the enzyme "All enzymes are proteins." This statement is now modified Which one of the following enzyme contains Mn metallic ion 29. because an apparent exception to this biological truth is [BHU 2000] as the prosthetic group [DUMET 2010] Or Which of the following enzyme is not usd in making (a) Spliceosome (b) Ribozyme [DPMT 2007] detergent (d) RNA poly III (c) RNA poly I (b) Dehydrogenase (a) Phosphatase Which one of the following statements regarding enzyme 22. (c) Peptidase (d) Catalase [CBSE PMT 2005] inhibition is correct Three of the following statements about enzymes are correct 30. (a) Competitive inhibition is seen when a substrate competes and one is wrong. Which one is wrong with an enzyme for binding to an inhibitor protein [CBSE PMT (Mains) 2010; NEET (Karnataka) 2013] (b) Competitive inhibition is seen when the substrate and (a) Enzymes require optimum pH for maximal activity the inhibitor compete for the active site on the enzyme (b) Enzymes are denatured at high temperature but in (c) Non-competitive inhibition of an enzyme can be certain exceptional organisms they are effective even at overcome by adding large amount of substrate temperatures 80°-90°C

(c) Enzymes are highly specific

(d) Most enzymes are proteins but some are lipids

Which type of reaction is shown by the following figure

[NCERT]

Formation of both peptide and glycosidic bonds involves

[DUMET 2010]

- (a) Hydration
- (b) Denaturation
- (c) Dehydration
- (d) Hydrolysis
- 32. Transition state structure of the substrate formed during an enzymatic reaction is **[NEET 2013]**
 - (a) Permanent and stable
- (b) Transient but stable
- (c) Permanent but unstable (d) Transient and unstable 33. An organic substance bound to an enzyme and essential for
- its activity is called [CBSE PMT 2006; AIIMS 2009]

Non-protein part of an enzyme is known as

[AFMC 1997; Odisha PMT 2002; BVP 2003]

- (a) Apoenzyme
- (b) Isoenzyme
- (c) Coenzyme
- (d) Holoenzyme
- An enzyme acts by [MP PMT 1992; AIEEE Pharmacy 2003]
 - (a) Reducing the energy of activation
 - (b) Increasing the energy of activation
 - (c) Decreasing the pH
 - (d) Increasing the pH
- 35. The protein part of enzyme is known as [MP PMT 1996: AIIMS 2000; BVP 2000; Odisha JEE 2012; AFMC 2012]

The enzyme which combines with non-protein part to form a functional enzyme known as IBHU 20041

- (a) Holoenzyme
- (b) Apoenzume
- (c) Isoenzyme
- (d) All of the above
- 36. Which enzyme shows greatest substrate specificity

[CPMT 2005]

[BHU 1995, 2000]

- (a) Nuclease
- (b) Trypsin
- (c) Sucrase
- (d) Pepsin
- 37. Which one of the following statements is correct with reference to enzymes

[Odisha JEE 2009; KCET 2011; NEET 2017]

- (a) Apoenzyme = Holoenzyme + Coenzyme
- (b) Holoenzyme = Apoenzyme + Coenzyme
- (c) Coenzyme = Apoenzyme + Holoenzyme
- (d) Holoenzyme = Coenzyme + Co-factor
- 38. Number of active sites in allosteric enzyme is [CPMT 2000]
 - (a) One
- (b) Two
- (c) Three
- (d) Four
- 39. Which one value is required for better enzymatic action

 - (a) High Ki
 - (c) Low Km
- (b) Low Ki (d) High Km
- 40. Cofactor (prosthetic group) is a part of holoenzyme. It is [CBSE PMT 1997; Odisha JEE 2011]
 - (a) Loosely attached inorganic part
 - (b) Accessory non-protein substance attached firmly
 - (c) Loosely attached organic part
 - (d) None of these
- 41. The permeases are [MP PMT 2003]
 - (a) Structural membrane proteins
 - (b) Enzymatic membrane proteins
 - (c) Carrier membrane proteins
 - (d) None of these

Which one of the following is not true for enzymes

[WB JEE 2012]

- (a) They act on a specific substrate
- (b) They are made up of fat and sugar
- (c) They act at a specific temperature
- (d) They act at a specific pH
- Co-enzyme is

[BHU 1994; NEET 2013]

- (a) Always a protein
- (b) Often a vitamin
- (c) Always an inorganic compound
- (d) Often a metal
- Which of the following enzyme can form RNA from DNA

[MP PMT 1992]

- (a) Restriction enzyme
- (b) DNA polymerase
- (c) RNA polymerase
- (d) Reverse transcriptase
- Inhibitory effect of melonic acid on succinic dehydrogenase enzyme is [NCERT; AIIMS 2003]
 - (a) Competitive inhibition
 - (b) Non-competitive inhibition
 - (c) Feedback inhibition
 - (d) Inhibition due to end product
- 46. Lactose operon is considered to be glucose sensitive due to

[DPMT 2003]

- (a) Catabolite induction
- (b) Allosteric inhibition
- (c) Anabolic inhibition
- (d) None of these
- FAD or FMN is a coenzyme. Which vitamin is incorporated into its structure [AIIMS 2009]
 - (a) Vitamin C
- (b) Vitamin B,
- (c) Vitamin B₆
- (d) Vitamin B₂ (Riboflavin)
- Which of the following enzymes has/have haem as a 48. prosthetic group
 - (i) Catalase
- (ii) Carboxypeptidase
- (iii) Succinic dehydrogenase (iv) Peroxidase
- (a) (i) Only
- (b) (i) and (ii)
- (c) (ii) and (iii)
- (d) (iii) and (iv)
- (e) (i) and (iv)
- 49. Which of the following is not a co-enzyme

[CPMT 2004; WB JEE 2010]

[Kerala PMT 2011]

[MP PMT 1993]

- (a) NAD
- (b) NADP
- (c) FAD

51.

- (d) ATP
- Enzymes capable of changing their form are called [DPMT 2003]
 - (a) Apoenzyme
- (b) Holoenzyme
- (c) Isoenzyme
- (d) Allosteric enzymes Enzymes as they exist inside the cell are
- (a) In solid form
- (b) In crystalline form
- (c) In colloidal form
 - (d) In solution form
- Select the type of enzyme involved in the following reaction 52. [Kerala PMT 2011]
 - $S-G+S'\rightarrow S+S'-G$
- (a) Dehydrogenase (c) Hydrolase
- (b) Transferase (d) Lyase
- (e) Isomerase

53. Template theory of enzyme action is supported by

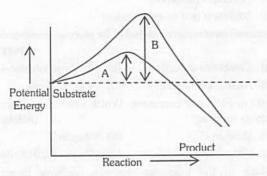

[BVP 2003]

- (a) Enzymes occur in living beings and speed up certain reactions
- (b) Enzymes speed up reaction
- (c) Enzymes determine the direction of reaction
- (d) Compounds similar to substrate inhibit enzyme activity
- Decline in the activity of the enzyme hexokinase by glucose
 phosphate is caused by [Kerala CET 2003]
 - (a) Non-competitive
- (b) Competitive inhibitions
- (c) Allosteric modulator
- (d) Denaturation of enzymes
- **55.** During glycolysis enzyme hexokinase changes glucose to glucose-6- phosphate. Glucose-6-phosphate is inhibited by

[CBSE PMT 1996]

- (a) Feedback inhibition
- (b) Positive feedback
- (c) Competitive inhibition
- (d) Non-competitive inhibition
- 56. Which of the following describes the given graph correctly

[NEET (Phase-II) 2016]

- (a) Exothermic reaction with energy A in absence of enzyme and B in presence of enzyme
- (b) Endothermic reaction with energy A in presence of enzyme and B in absence of enzyme
- (c) Exothermic reaction with energy A in presence of enzyme and B in absence of enzyme
- (d) Endothermic reaction with energy A in absence of enzyme and B in presence of enzyme

Classification and factors affecting enzyme

- Enzymes that catalyse inter-conversion of optical, geometrical or positional isomers are [DUMET 2009]
 - (a) Ligases
- (b) Lyases
- (c) Hydrolases
- (d) Isomerases
- Systematic approach of naming enzymes has been recommended by the Commission on Enzymes of the
 - (a) International Union of Physiology
 - (b) International Union of Biochemistry
 - (c) International Union of Biotechnology
 - (d) International Union of Genetic Engineering
- Basically how many types of enzymes have been recognised by International Union of Biochemistry [MHCET 2000]
 - (a) 4

(b) 5

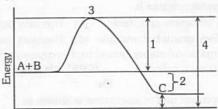

(c) 6

(d) 8

- In the modern system of nomenclature which one of the following enzyme occupies 1st position
 - (a) Oxidoreductase
- (b) Transferase
- (c) Hydrolase
- (d) Ligase
- 5. The plant proteinases or endopeptidases enzyme is

[CPMT 1994]

- (a) Urease
- (b) Papain
- (c) Pepsin
- (d) Trypsin
- See the following figure and identify 1, 2, 3 and 4 from the list I to IV

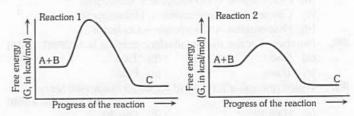

Progress of the reaction

- I. Segment representing the energy of activation
- II. Segment representing the amount of free energy released by the reaction
- III. Transition state
- IV. Segment would be the same regardless of whether the reaction were uncatalysed or catalysed. Which one is

corr	ect			[NCERT]
77 = 1	1	II	III	IV
(a)	1	2	4	3
(b)	1	3	2	4
(c)	1	2	3	2
(d)	1	3	2	4

- 7. Zymogens are
 - (a) Enzyme acting upon starch
 - (b) Group of zymase enzymes
 - (c) Inactive enzyme precursors
 - (d) None of the above
 - The two chemical reactions are showing in the following figure. Which statement is correct for reaction 1 [NCERT]

- (a) Slower and more exergonic than 2
- (b) Slower and more endergonic than 2
- (c) Faster and more exergonic than 2
- (d) Faster and more endergonic than 2
- At the time of cotton seeds germination, the stored food is digested by [CPMT 1996]

Or

Which one of the following enzyme is composed of simple proteins

- (a) Diastase
- (b) Maltase
- (c) Lipase
- (d) Amylase

OOK DEPOT 19

Fat is hydrolysed by enzyme lipase to yield

[RPMT 2002; CBSE PMT 2004; MP PMT 2012]

- (a) Fatty acid and amino acids
- (b) Glycerol and fatty acids
- (c) Glycerine and water
- (d) Glycerol and amino acids
- 11. Substrate of amylase enzyme is
 - (a) Protein
- (b) Fat
- (c) Starch
- (d) Sucrose
- 12. Enzyme which hydrolyses starch to maltose is

[MP PMT 1999]

[NCERT]

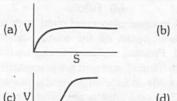

- (a) Lactase
- (b) Protease
- (c) Maltase
- (d) Amylase
- 13. Which one is not an example for hydrolases

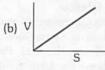

[Kerala PMT 2004]

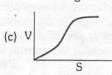

Or

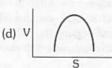

Hydrogen is removed from a substrate with the help of enzyme

- (a) Dehydrogenase
- (b) Protease
- (c) Amylase
- (d) Esterase
- (e) Sucrase
- Which graph shows the relationship between the rate of an enzymatic activity and substrate conc.(S)

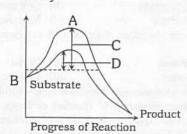

The figure given below shows the conversion of a substrate into product by an enzyme. In which one of the four options (a-d) the components of reaction labelled as A, B, C and D are identified correctly

	A	В	C	D
(a)	Potential energy	Transition state	Activation energy with enzyme	Activation energy without enzyme
(b)	Transition state	Potential energy	Activation energy without enzyme	Activation energy with enzyme
(c)	Potential energy	Transition state	Activation energy with enzyme	Activation energy without enzyme
(d)	Activation energy with enzyme	Transition state	Activation energy without enzyme	Potential energy

16. Enzyme concerned with transfer of electrons are

[NCERT; MP PMT 1998, 2002, 03]

- (a) Hydrolase
- (b) Dehydrogenase
- (c) Transaminase
- (d) Desmolase
- Enzyme having different molecular arrangement but similar functions is [BVP 2003, 04]

Or

Enzymes which are slightly different in molecular structure but can perform identical activity are called

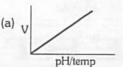

- (a) Isoenzyme
- (b) Holoenzyme
- (c) Apoenzyme
- (d) Co-enzume
- Allosteric modulation is due to the inhibition action of enzyme by [Kerala PMT 2006]
 - (a) Competitive inhibition
- (b) Substrate concentration
- (c) Products of reaction
- (d) Enzyme concentration
- (e) Non competitive inhibition
- Which one of the following pairs is wrongly matched

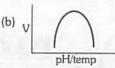

[CBSE PMT 2009]

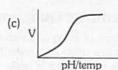

- (a) Detergents lipase
- (b) Alcohol nitrogenase
- (c) Fruit juice pectinase
- (d) Textile amylase
- 20. Modern detergents contain enzyme preparations of
 - [CBSE PMT 2008]
 - (a) Thermoacidophiles
- (b) Thermophiles
- (c) Acidophiles
- (d) Alkaliphiles
- Signaling between cells usually results in the activation of protein [DUMET 2009]
 - (a) Lipases
- (b) Kinases
- (c) Proteases
- (d) Nucleases
- 22. With reference to enzymes, turnover number means

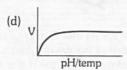

[KCET 2010]

- (a) The number of substrate molecules that a molecule of an enzyme converts into products per hour
- The number of substrate molecules that a molecule of (b) an enzyme converts into products per second
- (c) The number of substrate molecules that a molecule of an enzyme convert into products per minute
- (d) The number of substrate molecules that a molecule of an enzyme converts into products per day
- 23. Which graph represents the effect of pH/temp on the velocity of a typical enzymatic reaction (V)

- The effectiveness of an enzyme is affected least by [DUMET 2009]
 - (a) Temperature
 - (b) Concentration of the substrate
 - (c) Original activation energy of the system
 - (d) Concentration of the enzyme
- The enzyme which converts glucose into ethyl alcohol (C_2H_5OH) is [MP PMT 1998, 2003;
 - (a) Diastase
- (b) Maltase
- (c) Zymase
- (d) Invertase

AMU (Med.) 2006; BHU 2006]

26. The enzymes ribulose biphosphate carboxylase-oxygenase and phosphoenol pyruvate carboxylase are activated by

[AMU (Med.) 2009]

- (a) Mg
- (c) Mo

(b) Zn (d) Mn

27. The curve given below show enzymatic activity with relation to three conditions (pH, temperature and substrate concentration)

X-axis

What do the two axises (x and y) represent

[NCERT; CBSE PMT (Pre.) 2011] Y-axis

Temperature

X-axis

(a) Enzymatic activity

- (b) Enzymatic activity
 - pH
- Temperature
- Enzyme Activity Enzymatic Activity
- (d) Substrate concentration 28. The nucleic acids are broken into nucleotides by...... [J & K CET 2002]
 - (a) Amylases
- (b) Nucleases
- (c) Lipases
- (d) Proteases
- 29. Which one of the following is wrongly matched

[Kerala PMT 2009]

- (a) Fungi
- Chitin
- (b) Phospholipid
- Plasma membrane Lipopolysaccharide
- (c) Enzyme (d) ATP
- Nucleotide derivative
- (e) Antibody Glycoprotein
- 30. As temperature changes from 3°C to 45°C, the rate of enzyme activity will **IMP PMT 19961**

Or

- (a) Decrease and then increase (b) Increase and then decrease
- (c) Increase only
- (d) Decrease only
- 31. Which enzyme helps in removing oil stains from clothes

[BHU 2008]

Which enzyme digests the stored food material of castor seeds

- (a) Streptokinase
- (b) Trypsin
- (c) Lipase
- (d) Amylase

Exemplar Questions

It is said that elemental composition of living organisms and that of inanimate objects (like earth's crust) are similar in the sense that all the major elements are present in both. Then what would be the difference between these two groups. Choose a correct answer from among the following

[NCERT]

- (a) Living organisms have more gold in them than inanimate objects
- (b) Living organisms have more water in their body than inanimate objects
- (c) Living organisms have more carbon, oxygen and hydrogen per unit mass than inanimate objects
- (d) Living organisms have more calcium in them than inanimate objects

- Many elements are found in living organisms either free or in the forms of compounds. One of the following is not, found in living organisms [NCERT]
 - (a) Silicon
- (b) Magnesium
- (c) Iron
- (d) Sodium
- Aminoacids, as the name suggests, have both an amino group and a carboxyl group in their structure. In addition, all naturally occurring aminoacids (those which are found in proteins) are called L-aminoacids. From this, can you guess from which compound can the simplest aminoacid be made [NCERT]
 - (a) Formic acid
- (b) Methane
- (c) Phenol
- (d) Glycine
- Many organic substances are negatively charged e.g., acetic acid, while others are positively charged e.g., ammonium ion. An aminoacid under certain conditions would have both positive and negative charges simultaneously in the same molecule. Such a form of aminoacid is called

- (a) Positively charged form (b) Negatively charged form
- (c) Neutral form
- (d) Zwitterionic form
- Sugars are technically called carbohydrates, referring to the 5. fact that their formulae are only multiple of C(H2O). Hexoses therefore have six carbons, twelve hydrogens and six oxygen atoms. Glucose is a hexose. Choose from among the following another hexose [NCERT]
 - (a) Fructose
- (b) Erythrose
- (c) Ribulose
- (d) Ribose
- When you take cells or tissue pieces and grind them with an acid in a mortar and pestle, all the small biomolecules dissolve in the acid. Proteins, polysaccharides and nucleic acids are insoluble in mineral acid and get precipitated. The acid soluble compounds include aminoacids, nucleosides, small sugars etc. When one adds a phosphate group to a nucleoside one gets another acid soluble biomolecule calle

[NCERT]

[NCERT]

- (a) Nitrogen base
- (b) Adenine
- (c) Sugar phosphate
- (d) Nucleotide
- When we homogenise any tissue in an acid the acid soluble pool represents [NCERT]
 - (a) Cytoplasm
- (b) Cell membrane
- (c) Nucleus (d) Mitochondria 8. The most abundant chemical in living organisms could be
 - (a) Protein
- (b) Water
- (c) Sugar
- (d) Nucleic acid
- 9. A homopolymer has only one type of building block called monomer repeated 'n' number of times. A heteropolymer has more than one type of monomer. Proteins are heteropolymers made of aminoacids. While a nucleic acid like DNA or RNA is made of only 4 types of nucleotide monomers, proteins are made of [NCERT]
 - (a) 20 types of monomers
- (b) 40 types of monomers
- (c) 3 types of monomers
- (d) only one type of monomer
- Proteins perform many physiological functions. For 10. example, some functions as enzymes. One of the following represents an additional function that some proteins discharge [NCERT]
 - (a) Antibiotics
 - (b) Pigment conferring colour to skin
 - (c) Pigments making colours of flowers
 - (d) Hormones

DOK DEPOT 19

11. Glycogen is a homopolymer made of

(a) Glucose units

(c) Ribose units

(b) Galactose units

- 12.
- (d) Aminoacids
- The number of 'ends' in a glycogen molecule would be [NCERT]
 - Equal to the number of branches plus one
 - (b) Equal to the number of branch points
 - One (c)
- (d) Two, one on the left side and another on the right side
- 13. A pure protein should normally have

(a) Two ends

[NCERT]

[NCERT]

- (c) Three ends
- (b) One end (d) No ends
- 14. Enzymes are biocatalysts. They catalyse biochemical reactions. In general they reduce activation energy of reactions. Many physico-chemical processes are enzyme mediated. Some examples of enzyme mediated reactions are given below. Tick the wrong entry
 - (a) Dissolving CO₂ in water
 - (b) Unwinding the two strands of DNA
 - (c) Hydrolysis of sucrose
 - (d) Formation of peptide bond

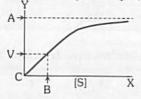

Critical Thinking

Objective Questions

1. Which one out of A-D given below correctly respresents the structural formula of the basic amino acid INCERT CRCE

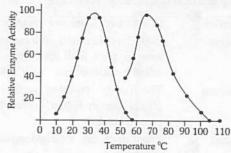

Α.			E PMT (Pre.) 20
A	В	С	D
NH ₂	NH ₂	CH ₂ OH	NH ₂
H - C - COOH	Н-С-СООН	CH ₂	н-с-соон
CH ₂	CH ₂	CH ₂	CH ₂
CH ₂	1	NH ₂	CH ₂
C	ОН		CH ₂
б он			CH ₂
	200-		NH _o
(a) C		(b) D	

- 2. The given adjacent graph depicts the change in conc. of substrate on enzyme activity. Identify A, B and C [NCERT]

	A	В	C
(a)	K _m	V _{max}	$\frac{V_{\text{max}}}{2}$
(b)	V _{max}	K _m	V _{max}
(c)	$\frac{V_{\text{max}}}{2}$	K _m	Ki
(d)	Ki	K _m	V _{max}

- 3. Enzymes generally have
 - (a) Same pH and temperature optima
 - (b) Same pH but different temperature optima
 - (c) Different pH but same temperature optima
 - (d) Different pH and different temperature optima
- Most of the biochemical reactions differ from those occuring in the non-living world in
 - (a) Requiring energy
- (b) Releasing energy
- (c) Being enzymatic
- (d) Being spontaneous
- A phosphoglyceride is always made up of
 - [NEET 2013] (a) A saturated or unsaturated fatty acid esterified to a phosphate group which is also attached to a glycerol molecule
 - (b) Only a saturated fatty acid esterified to a glycerol molecule to which a phosphate group is also attached
 - Only a unsaturated fatty acid esterified to a glycerol molecule to which a phosphate group is also attached
 - (d) A saturated or unsaturated fatty acid esterified to a glycerol molecule to which a phosphate group is also attached
- 6. The given graph depicts the effect of temperature on the activity of the two enzymes A and B that catalyze the same reaction. Select the correct statement (s) for these results

- A. The rate of reaction in each case increases with increase in temperature and declines at higher temperatures due to denaturation of the enzyme
- Both the enzymes A and B are thermolabile
- C. At higher temperature the reactants become highly energized and fail to interact with active site, thus decreasing the rate of reaction
- The enzyme A is from a mesophilic organism, whereas the enzyme B is from a thermophilic organism [NCERT]
- (a) A, B, D
- (b) C and D
- (c) B and C
- (d) A and B
- 7. In the modern system of nomenclature which one of the following enzyme occupies 6th position
 - (a) Ligase
- (b) Isomerase
- (c) Lyase

8.

- (d) Hydrolase
- The most important property of an enzyme is its (a) Composition
 - (b) Thermal denaturation
 - (c) Specificity
- (d) Solubility
- 9.
 - The ratio of the enzyme to substrate molecule can be as high as
- (a) 1:1000 (c) 1:10,00,000
- (b) 1:1,00,000
- 10. Repressible enzymes are formed
- (d) 1:50,000 [DPMT 2006]
- (a) In the absence of corepressor
 - (b) In the presence of corepressor
 - (c) In the presence of apressor

 - (d) All of the above

The enzyme nitrogenase is extremely sensitive to

[WB JEE 2016]

[NEET 2017]

- (a) Oxygen
- (b) Nitrogen
- (c) Hydrogen
- (d) Helium
- Which of the following are not polymeric 12.

 - (a) Nucleic acids
- (b) Proteins
- (c) Polysaccharides
- (d) Lipids

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- If both the assertion and reason are true but the reason is (b) not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- 1. Assertion DNA is associated with proteins.
 - Reason DNA binds around histone proteins that form a pool and the entire structure is
 - called a nucleosome. [AIIMS 2000]
- 2. The bonds attaching second and third Assertion phosphates in higher nucleotide are high energy bonds.
 - Reason The bonds are attached against force of repulsion.
- Assertion Enzymes have active sites and substrates
- reactive sites, on their surfaces respectively. Reason
 - Active and reactive sites push the enzyme and substrate molecules away from each [AIIMS 1999]
- 4. Assertion Enzyme substrate complex remains throughout the reaction.
 - Reason The greater the affinity of the enzyme for a substrate, the higher is the catalytic activity.
- 5. Assertion Desmolysing enzymes are those which catalyse the reactions by hydrolysis.
 - Reason Digestive enzymes are hydrolysing in nature.
- 6. Assertion Coenzymes are also called prosthetic groups.
 - Reason Coenzymes and prosthetic groups are cofactors.
- 7. Assertion Enzymes are defined as biological proteins.
 - Reason Chemically all enzymes are globular [AIIMS 1997] proteins.
- 8. DNA molecules and RNA molecules are Assertion found in the nucleus of cell.
 - Reason On heating, enzymes do not lose their specific activity. [AIIMS 1994]

- The higher the turn-over number the more Assertion
 - efficient an enzyme is.
 - Reason It is not dependent upon the number of
 - active sites present over an enzyme.
- Allosteric enzymes show 10. Assertion feed back
 - inhibition.
 - Reason The inhibitor is competitive.
- 11. Assertion Enzyme becomes inactive below minimum
 - temperature.
 - The inactivity of the enzymes is due to Reason
 - denaturation.
- 12. Assertion Enzymes lower the activation energy.
 - Reason A substrate molecule can be acted upon by
 - a particular enzyme. [AIIMS 2011]

Answers and Solutions

Carbohydrates, Starch and Protein

- (a) Simple sugar i.e., monosaccharide. These are the simplest carbohydrates and are building units of complex carbohydrates. i.e., Starch and cellulose.
- (a) Fructose is the most common form of sugar. It is the sweetest among naturally occurring sugars. It has sweetening index of 170 (where as the sweetening index of glucose is 70).
- (c) Inulin is homopolysaccharides, which is found in the root of dahlia plant.
- (b) Pentoses and hexoses are the example of monosaccharides.
- (b) Due to heating effect, disaccharides are dissociated into monosaccharides, which are sweet in nature.
- (a) Sucrose is the common cane or table sugar which is composed of D-glucose and fructose attached together by the aldehyde and ketone carbon.
- 12. (d) The carbohydrates or sugar where free aldehyde or ketonic group is absent (utilized in glycosidic bond formation) can not reduce the above reagents are called non-reducing sugar i.e., Sucrose, glycogen, starch.
- (d) Dextran is a complex polysaccharide prepared either through partial hydrolysis of starch or polymerization of sucrose by the bacterium Leuconostoc mesenteroides.
- 17. (d) The non proteineous prosthetic group is FMN or FAD. The protein is flavoprotein, which is a type of conjugated protein.
- **18.** (d) When protein adjoins with carbohydrates, is known as glycoprotein, which is a conjugated protein.
- (c) No cell could live without protein because proteins are building block of the body.
- **28.** (a) Lysine is an essential amino acid found in wheat. Which is not synthesized in the human body.
- 34. (a) The union makes sucrose more stable than other sugars because both its anomeric carbon atoms are protected from oxidative attack. It is because of this reason, sucrose is used for transporting carbohydrates in plants.
- 45. (b) Disaccharides composed of two unit of monosaccharides e.g. sucrose, maltose and lactose etc. Starch is the most common storage polysaccharide in plants.
- **47.** (a) Peptone is a derived protein. Others are conjugated proteins.
- 48. (c) The fatty acids having more than one double bond are called polyunsaturated fatty acids. Fats having such fatty acids are termed polyunsaturated fats. The latter are commended by physicians for persons having cardiovascular disease as their use lowers the blood cholesterol level.
- **58.** (b) Polymer of N-acetyleglucosamine $(C_8H_{13}O_5N)_n$ that forms exoskeleton of arthropods and cell wall of fungi.
- (a) Ester bonds are formed in nucleic acids and lipids, but not proteins

Nucleotides and Nucleic acid

- **12.** (a) There is double hydrogen bond between adenine and thymine (A = T) and triple bond between cytosine and quanine $(C \equiv G)$.
- 16. (d) Because plant viruses have RNA as genetic material.
- 17. (a) The two strands of DNA molecules run in opposite or antiparallel direction due to presence of hydrogen bond because two base i.e. one in each chain of DNA molecule, joined together by hydrogen bonds.
- **21.** (b) Adenine and thymine; because *C* always attaches with *G* and *A* attaches with *T*.
- 25. (b) RNA is present both inside and outside the nucleus.

Introduction, properties, action and inhibition of enzyme

- (b) The term enzyme was used by Willy Kuhne while working on fermentation.
- (d) Zymase is complex of enzyme. It obtained from yeast cell by Edward Buchner.
- (b) All enzymes are proteins but all proteins are not enzyme.
- (a) Arber and Nathans got nobel prize in 1978 for the discovery of restriction endonucleases.
- 6. (a) Lock and key theory: Emil Fischer proposed this theory, according to which on the surface of enzymes a few elevations and ditches are found known as active sites and enzymes bind reactants on these sites to create reaction between them.
- (a) First time fermentative enzymes were discovered from yeast.
- (c) Because enzymes are made up of proteins which are basically polymers of amino acids.
- 17. (c) In competitive inhibition, km value increases.
- 19. (d) Viruses are acellular organisms.
- 24. (c) Km is a Michaelis Menten constant, which indicates the substrate concentration at which the chemical reaction catalysed by an enzyme attains half its maximum velocity.
- 26. (d) Inhibition of succinic dehydrogenase by malonate is an example of competitive inhibition. This is reversible reaction. On increasing the substrate (succinate) concentration the effect of inhibitor is removed and V_{max} remain same.
- 29. (c) Enzymes used as biological detergents

Application	Enzyme used	Uses
Biological detergents	Primarily Proteases, Produced in an extracellular form by bacteria.	Used for the pre- soak or main wash, break down protein stains or clothes; also used in dishwashers to remove food residues.
	Amylases	Remove starch stains from clothes also used ir dishwashers to remove resistan starch residues.
	Cellulase	Softens and brightens colour o cotton fabrics.

- 30. (d) Most enzymes are proteins but some are lipids.
- 33. (c) Coenzymes are loosely attached complex non-protein, low molecular weight, thermostable, organic or mettaloorganic groups. Which readily separate from the apoenzyme.
- 34. (a) In each and every molecule energy of activation is found, in which a few have more while others have less energy. Enzymes facilitates in between two molecules lowering their energy of activation.
- 35. (b) The proteinaceous part of an enzyme is called apoenzyme. The apoenzyme plus non proteinaceous part is called holoenzyme.
- 38. (b) One is active site and second is allosteric site.
- **41.** (c) Permeases are found in the plasma membrane of the cell. Which take part in transportation of ions etc.
- (d) Flavin mononucleotide (FMN), Flavin adenine dinucleotide (FAD) contains riboflavin (vitamin B₂).
- 49. (d) Co-enzymes are organic molecules which acts as cofactors, but unlike prosthetic groups they do not remain attached to the enzyme between reaction. NAD, NADP and FAD are co-enzymes whereas ATP is an energy carrier in cell.
- 53. (d) The best evidence of lock and key theory or template theory of enzyme action comes from the observation that compounds similar in structure to the substrate inhibit the reaction.
- 54. (c) The substance which causes change in allosteric sites are known as modulators. They are of two types activator and inhibitor. Hexokinase is the example of inhibitor modulator.

Classification and factors affecting enzyme

- (c) Zymogens: These are inactive enzyme precursors which in need can be convert in enzymes.
- (d) Amylase digest the stored food material of germinated cotton seed.
- **15.** (b) Activation energy is required for overcoming the energy barrier which gets reduced in the presence of enzyme.
- 17. (a) Isoenzymes: A few enzymes are isomerically equal to others and are only differing in their molecular structure.
- **25.** (c) $C_6H_{12}O_6 \xrightarrow{\text{Yeast}} C_2$ $\supset H + 2CO_2$.
- 27. (c) X-axis represent temp ature and Y-axis represent enzyme activity. All enzymes act at an optimum temperature, above and below this temperature the enzyme activity declines.
- 30. (b) If temperature increases from 3°C to 45°C, firstly it reaches to optimum condition and later temperature conditions are not optimum for enzyme activity. Thus the rate of enzyme activity initially increases and then decreases.

Critical Thinking Questions

- **3.** (c) Each enzyme has its own different favourable *pH* value but same temperature optima.
- (c) Biochemical reactions of living beings are different from non-living world because in non-living beings, catalysts of reactions are mostly inorganic metals.
- (c) Because a particular enzyme can catalyse only a particular type of reaction.
- (c) Enzymes show reversible reactions and act by lowering energy of activation by more than 50%. They work in milliseconds and rate of enzyme to substrate is as high as 1:1000000.
- 10. (a) Some enzymes are normally present in cell but their synthesis is ceased when the concentration of their end product become high, such enzymes are called repressible enzymes whereas the end product is called corepressor.

A regulator gene produces the aporepressor which unites with corepressor to form a functional repressor molecule. This repressor molecule inhibit mRNA synthesis by all genes specifying **enzymes**.

Assertion and Reason

- 1. (a) A chain of DNA has 140 base pairs, make $1\frac{3}{4}$ turns and twist around a histone octamer forming nucleosome. The core of nucleosome consists of 4 histones H_2A, H_2B, H_3 and H_4 .
- 2. (a) Nucleotides having more than one phosphate group are called higher nucleotides. The second and third phosphates of higher nucleotides are attached against forces of repulsion between similarly charged phosphate radicals. Hence, the bonds attaching second and third phosphates are higher energy bonds.
- (c) Enzyme has specific site for substrates called as active sites and substrate has reactive sites. These active and reactive sites help in making of substrates enzyme complex.
- 4. (e) The enzymes substrate complex is short lived. The substrate is changed into products. The products remain complexed with the active site of the enzyme for a brief period. They soon separate and the active site is free to perform another catalytic act. Enzymes activity depends upon their affinity of substrates. If turnover number of substrate is higher, then enzymes show high affinity towards substrate. The number of substrate molecules changed per minute by a molecule or enzyme is called turn over number.

- 6. (e) Desmolysing enzymes are those which catalyse reactions by the other methods other than hydrolysis, e.g., aldolases, dehydrogenases, oxidases, etc. Digestive enzymes function by catalysing hydrolysis. Larger molecules are broken into smaller ones. They are grouped into three types proteolytic (breaks protein molecule), amylolytic (breaks sugar molecule) and lipolytic (breaks lipid molecule).
- 6. (e) Cofactor may be inorganic or organic in nature. Organic cofactors are of two types, coenzymes and prosthetic groups. Coenzymes are easily separable nonprotein organic cofactors. Prosthetic groups are nonprotein organic cofactors firmly attached to apoenzymes (protein part of enzyme).
- 7. (a) We know that all biological reactions are catalysed by special catalysts called enzyme, thus enzymes are defined as biological proteins. We also know that enzymes are small organic molecules which are weakly held to the protein and can be easily seperated by dialysis. Therefore chemically all enzymes are globular proteins.
- 8. (d) We know that DNA molecules are found primarly in the nucleus of the cell but RNA molecules are found outside the nucleus. By heating, its special structural arrangement is changed irreversibly, this result in the conversion of enzyme into a fibrous or insoluble form. Due to this irreversible change, enzymes lose their specific activity when heated.
- 9. (c) The number of substrate molecules changed per minute by a molecule or enzyme is called turn over number. The higher the turn-over number, the more efficient an enzyme is. It depends upon the number of active sites present over an enzyme.
- 10. (c) Feed back inhibition is a type of reversible inhibition found in allosteric enzymes. The inhibitor is noncompetitive and is usually a low molecular intermediate or product of metabolic pathway having a chain of reactions involving a number of enzymes.
- 11. (c) Enzyme becomes inactive below minimum temperature. Low temperature preserves the enzymes in the inactive state. High temperature destroys enzymes by causing their denaturation.
- 12. (b) Activation energy is an external supply of energy which is needed for the initiation of the chemical reaction. Activation energy required for such a large number of reactions cannot be provided by living systems. Enzymes lower the activation energy required for a reaction. Enzymes are generally specific for their substrates.

FT Self Evaluation Test

- Raphides are found in 1.
 - (a) Dahlia
- (b) Asparagus
- (c) Nut
- (d) Guava
- Which level of protein structure is affected by DNA 2.
 - (a) Primary structure
- (b) Secondary structure
- (c) Tertiary structure
- (d) Quaternary structure
- Insoluble carbohydrate inulin is commonly found in 3.

[Odisha JEE 2009]

[MP PMT 2011]

IBHU 1995]

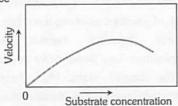

- (a) Root of beet
- (b) Stem of sugarcane
- (c) Fruit of grapes
- (d) Roots of Dahlia
- Rihose is a 4.
- [MP PMT 2011]
- (a) Monosaccharide
- (b) Disaccharide
- (c) Polysaccharide
- (d) None
- 5.
- The unit of cellulose is
- (a) Glucose
- (b) Fructose
- Mannose (c)
- (d) Galactose
- 6. Which is true about enzymes
 - (a) Lower the energy of activation of a reaction
 - (b) Make the equilibrium more favourable for the organism
 - (c) Lower the energy of product and increases the energy of reactant
 - (d) Are altered permanently in the reaction they catalyse
- Papain produced from 7.

[Odisha JEE 2009]

- (a) Carica papaya
- (b) Glycine max
- (c) Citrus sp
- (d) Ficus carica
- What enzymes do for a biochemical reaction
 - (a) Alter its rate
- (b) Alter its pattern
- (c) Alter both
- (d) None of the above
- The enzymes required to obtain protoplasts are 9.

[AMU (Med.) 2006; Odisha JEE 2008]

- (a) Cellulase and proteinase (b) Cellulase and amylase
- (c) Cellulase and pectinase (d) Amylase and pectinase
- Enzymes have a very narrow optima for 10.
 - (a) Light
- (b) Temperature
- (c) pH
- (d) Humidity
- The given graph shows the effect of substrate concentration on the rate of reaction of the enzyme green gramphosphatase

What does the graph indicate

[AIIMS 2005, 08]

- (a) The rate of enzyme reaction is directly proportional to the substrate concentration
- (b) Presence of an enzyme inhibitor in the reaction mixture
- (c) Formation of an enzyme-substrate complex
- (d) At higher substrate concentration the pH increase

- Molecular weight of enzyme is 12.
 - (a) Less than 5000
 - (b) 5000 to 10000
 - (c) 10000 to 20000
 - (d) More than 40000
- The term 'feedback' refers to 13.
 - (a) The effect of end product on the rate of enzymatic reaction
 - (b) The effect of substrate on the rate of enzymatic reaction
 - (c) The effect of an external compound on the rate of enzymatic reaction
 - (d) The effect of enzyme concentration on its rate of reaction
- 14. Pepsin is inactivated at pH

- (a) Below 3
- (b) Below 2
- (c) Above 5
- (d) Above 3

Answers and Solutions

1	b	2	a	3	d	4	a	5	a
6	a	7	a	8	a	9	c	10	C
11	b	12	d	13	a	14	c		

- (b) Raphides are needle shaped structures of calcium oxalate. These are found in epidermal cells of Asparagus, Eichhornia, Lemna etc. Cell with raphides are called idioblasts.
- (d) Inulin is called 'Dahlia starch' and found in roots. 3.
- 6. (a) Enzyme act by decreasing the activation energy so that the number of activated molecules is increased at lower energy level.
- Each enzyme operates within a narrow range of pH. It 10. is most effective at a particular point of this range which is called optimum pH.
- 12. (d) Peroxidase one of the smaller enzymes has molecular weight of 4,000, where as catalase one of the largest has a molecular weight of 250,000.
- (c) All enzymes are temperature and pH specific in nature pepsin of gastric juice works well at pH2.

Cell division / Cell reproduction / Cell cycle

It is the process by which a mature cell divides and f+orms two nearly equal daughter cells which resemble the parental cell in a number of characters.

In unicellular organisms, cell division is the means of reproduction by which the mother cell produces two or more new cells. In multicellular organism also, new individual develop from a single cell. Cell division is central to life of all cell and is essential for the perpetuation of the species.

Discovery: Prevost and Dumans (1824) first to study cell division during the cleavage of zygote of frog. Nageli (1846) first to propose that new cells are formed by the division of pre-existing cells.

Rudolf Virchow (1859) proposed "omnis cellula e cellula" and "cell lineage theory".

A cell divides when it has grown to a certain maximum size which disturb the karyoplasmic index (KI)/Nucleoplasmic ratio (NP)/Kernplasm connection.

Cell cycle: Howard and Pelc (1953) first time described it. The sequence of events which occur during cell growth and cell division are collectively called cell cycle. Cell cycle completes in two steps:

- (1) Interphase, (2) M-phase/Dividing phase
- (1) **Interphase :** It is the period between the end of one cell division to the beginning of next cell division. It is also called resting phase or not dividing phase. But, it is actually highly metabolically active phase, in which cell prepares itself for next cell division. In case of human beings it will take approx 25 hours. Interphase is completed into three successive stages.
- G_1 phase/Post mitotic/Pre-DNA synthetic phase/gap $I^{\rm st}$: In which following events take place.
 - (i) Intensive cellular synthesis.
 - (ii) Synthesis of rRNA, mRNA ribosomes and proteins.
 - (iii) Metabolic rate is high.
 - (iv) Cells become differentiated.
 - (v) Synthesis of enzymes and ATP storage.
 - (vi) Cell size increases.
 - (vii) Decision for a division in a cell occurs.
 - (viii) Substances of G stimulates the onset of next S phase.

(ix) Synthesis of NHC protein, carbohydrates, proteins, lipids.

3.3

(x) Synthesis of enzyme, amino acids, nucleotides etc. but there is no change in DNA amount.

S-phase/Synthetic phase

- (i) DNA replicates and its amount becomes double (2C 4C).
- (ii) Synthesis of histone proteins and NHC (non-histone chromosomal proteins).
 - (iii) Euchromatin replicates earlier than heterochromatin.

G2-phase/Pre mitotic/Post synthetic phase/gap-IInd

- (i) Mitotic spindle protein (tubulin) synthesis begins.
- (ii) Chromosome condensation factor appears.
- (iii) Synthesis of 3 types of RNA, NHC proteins, and ATP molecule.
- (iv) Duplication of mitochondria, plastids and other cellular macromolecular complements.
 - (v) Damaged DNA repair occur.
- (2) *M*-phase/Dividing phase/Mitotic phase: It is divided into two phases, karyokinesis and cytokinesis.

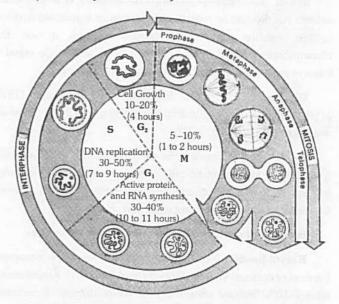

Fig: 3.3-1 Different stages of cell cycle (Mitotic cycle)

Duration of cell cycle : Time period for G_1 , S, G_2 and M-phase is species specific under specific environmental conditions. e.g., 20 minutes for bacterial cell, 8-10 hours for intestinal epithelial cell, and onion root tip cells may take 20 hours.

 G_0 – phase (Lajtha, 1963): The cells, which are not to divide further, do not proceed beyond the G_1 phase and start undergoing differentiation into specific type. Such cells are said to be in G_0 phase.

Types of cell division: It is of three types, Amitosis, Mitosis and Meiosis.

Amitosis

Amitosis (Gk. Amitos = without thread; osis = state). It is also called as direct cell division. It was discovered by Remak (1855) in RBC of chick embryo. In this division there is no differentiation of chromosomes and spindle. The nuclear envelope does not degenerate. The nucleus elongates and constricts in the middle to form two daughter nuclei. This is followed by a centripetal constriction of the cytoplasm to form two daughter cells. It is primitive type of division occurring in prokaryotes, protozoans, yeasts, foetal membrane of mammals, cartilage of mammals etc.

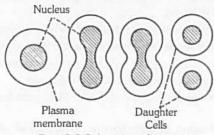

Fig: 3.3-2 Amitosis division

Mitosis

Mitosis (Gk. Mitos = thread; osis = state). It is also called indirect cell division or somatic cell division or equational division. In this, mature somatic cell divides in such a way that chromosomes number is kept constant in daughter cells equal to those in parent cell. So it is called equational division.

Discovery: Mitosis was first observed by *Strasburger* (1875) in plant cell and in animal cell by *W.flemming* (1879). Term mitosis was given by Flemming (1882).

Occurrence: Mitosis is the common method of cell division. It takes place in the somatic cells in the animals and plants. Hence, it is also known as the somatic division. In plants mitosis occurs in the meristematic cells *e.g.*, root apex and shoot apex.

Process of mitosis: Mitosis is completed in two steps.

Karyokinesis: (Gk. *Karyon* = nucleus; *kinesis* = movement) Division of nucleus. Term given by *Schneider* (1887). Karyokinesis it takes 5-10% (shortest phase) time of whole division. It comprises four phases *i.e.*, Prophase, Metaphase, Anaphase, Telophase.

- (1) Prophase: It is longest phase of karyokinesis.
- (i) Chromatin fibres thicken and shorten to form chromosomes which may overlap each other and appears like a ball of wool. i.e., Spireme stage.
- (ii) Each chromosome divides longitudinally into 2 chromatids which remain attached to centromere.
- (iii) Nuclear membrane starts disintegrating except in dinoflagellates.
 - (iv) Nucleolus starts disintegrating.
 - (v) Cells become viscous, refractive and oval in outline.
 - (vi) Spindle formation begins.
 - (vii) Cell cytoskeleton, golgi complex, ER, etc. disappear.
 - (viii) In animal cells, centrioles move towards opposite sides.
 - (ix) Lampbrush chromosomes can be studied well.
- (x) Small globular structure (beaded) on the chromosome are called chromomeres.
- (xi) Spindle is formed from centriole (in animal cells) or MTOC (microtubule organising centre) in plant cells successively called astral and anastral spindle.

(2) Metaphase

- (i) Chromosomes become maximally distinct i.e., size can be measured.
 - (ii) A colourless, fibrous, bipolar spindle appears.
- (iii) Spindle fibre are made up of 97% tubulin protein and 3% RNA.
- (iv) Chromosomes move towards equatorial plane of spindles called congression and become arranged with their arms directed towards pole and centromere towards equator.
 - (v) Spindle fibres attach to kinetochores.
- (vi) Metaphase is the best stage for studying chromosome morphology (structure, size, number).
 - (vii) Spindle has two type of fibres:
 - (a) Continous fibre (run from pole to pole).
 - (b) Discontinous fibre (between pole to centromeres).

(3) Anaphase

- (i) Centromere splits from the middle and two chromatids gets separated.
- (ii) Both the chromatids move towards opposite poles due to repulsive force called anaphasic movement.
- (iii) Anaphasic movement is brought about by the repolymerisation of continuous fibres and depolymerisation of chromosomal fibres. Formation and expansion of interzonal fibres.

- (iv) Different shape of chromosomes (V, J, I or L shapes) become evident during chromosome movement viz. metacentric acrocentric etc.
 - (v) The centromere faces towards equator.
- (vi) The chromatids are moved towards the pole at a speed of 1 μ m/minute. About 30 ATP molecules are used to move one chromosome from equator to pole.
 - (vii) Shape of chromosome is best studied at anaphase.

(4) Telophase

- (i) Chromosomes reached on poles by the spindle fibers and form two groups.
 - (ii) Chromosomes begin to uncoil and form chromatin net.
 - (iii) The nuclear membrane and nucleolus reappear.
 - (iv) Two daughter nuclei are formed.
 - (v) Golgi complex and ER etc., reform.
 - (vi) This phase is also known as reverse prophase.

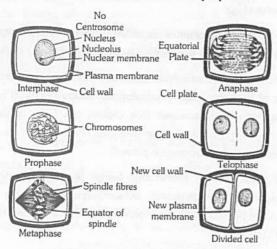

Fig: 3.3-3 Various stages of mitosis

Cytokinesis: (Gk –kitos = cell; kinesis = movement) Division of cytoplasm, Term given by *Whiteman* (1887). Division of cytoplasm into 2 equal parts.

Cytokinesis is by 2 methods:

- (1) Cell furrow method: This is characteristic of animal cells. Due to absence of rigid cell wall here, the more flexible plasmamembrane forms the outer layer of cell. A circular constriction or invagination appears at centre or equator, which deepens gradually and finally two daughter cells are separated.
- (2) **Cell plate method**: This is characteristic of plant cells. Here, vesicles provided by Golgi apparatus unite to form phragmoplasts, which join to form cell plate. Cell plate is first laid down in centre and then proceeds towards periphery (i.e., centrifugal plate-formation). Cell wall materials are now laid down on both sides of cell plate and thus forming two daughter cells.

Significance of mitosis

- (1) It keeps the chromosome number constant and genetic stability in daughter cells, so the linear heredity of an organism is maintained. All the cells are with similar genetic constituents.
- (2) It provides new cells for repair and regeneration of lost parts and healing of the wounds.
- (3) It helps in asexual reproduction by fragmentation, budding, stem cutting, etc.
- (4) Somatic variations when maintained by vegetative propagation can play important role in speciation.

Types of Mitosis

- (1) **Intranuclear or Promitosis**: In this nuclear membrane is not lost and spindle is formed inside the nuclear membrane *e.g.*, Protozoans (*Amoeba*) and yeast. It is so as centriole is present within the nucleus.
- (2) **Extranuclear or Eumitosis :** In this nuclear membrane is lost and spindle is formed outside nuclear membrane *e.g.*, in plants and animals.
- (3) **Endomitosis**: Chromosomes and their DNA duplicate but fail to separate which lead to polyploidy *e.g.*, in liver of man, both diploid (2N) and polyploid cells (4N) have been reported. It is also called endoduplication and endopolyploidy.
- (4) Dinomitosis: In which nuclear envelope persists and microtubular spindle is not formed. During movement the chromosomes are attached with nuclear membrane.

Mitotic poision: The agents which inhibit cell division.

- (1) Azides and Cyanides: Inhibit prophase.
- (2) Colchicine: Inhibits spindle formation at metaphase.
- (3) Mustard gas: Agglutinates the chromosomes.
- (4) Chalones: These were first reported by Laurence and Bullough (1960). They are peptides and glycoproteins secreted by extracellular fluid of healthy cells and inhibit cellular division.

Karyochoriosis: A type of mitosis in fungi in which is intranuclear nucleus divides by furrow formation.

Table : 3.3-1

Difference between animal and plant cells (Mitosis)

Animal cells	Plant cells			
Centrioles present at spindle poles.	Centrioles lacking at spindle poles. No asters are formed (anastral).			
Asters are formed (amphiastral).				
Cytokinesis by furrowing of cytoplasm.	Cytokinesis mostly by cell plate formation.			
Furrow extends centripetally	Cell plate grows centrifugally.			

Microfilament ring brings about cleavage.	Microfilaments have no role in cytokinesis.				
Occurs nearly in all tissues.	Occurs mainly at meristems.				
Cell becomes rounded and its cytoplasm more viscous at the time of mitosis.	Cell does not change form or nature at the time of mitosis.				
Midbody is formed at the equator of the spindle.	Equator of the spindle changes into phragmoplast.				
Intercellular spaces appear between the daughter cells.	Daughter cells remain adhered together by middle lamella.				
Animal mitosis is controlled by certain mitogens.	Plant mitosis is usually controlled by a hormone cytokinin.				

Meiosis

Meiosis (Gr. meio – to lessen, osis – state). Meiosis is a much slower process than mitosis. It is a double division that occurs in a mature diploid reproductive cell (2x) in which nucleus divides twice but chromosome (DNA) replicates only once to form four haploid cells, each having the half the number of chromosomes present in the parent cell. As it causes reduction in the number of chromosomes, it is known as **reduction division**. Meiosis in a cell occurs only once. The so formed haploid cells do not further undergo meiosis because there is no synaptinemal complex in haploid genome.

Discovery: It was first demonstrated by Van Beneden (1887) but was described by Winiwarter (1900). Term "meiosis" was given by Farmer and Moore (1905). Gregoire used the term meiosis I and II.

Occurrence: It is found in special types and at specific period. It is reported in diploid germ cells of sex organs (e.g., primary spermatocytes of testes to form male gametes called spermotozoa and primary oocytes to form female gametes called ova in animals) and in pollen mother cells (microsporocytes) of anther and megasporocyte of ovule of ovary of flowers in plant to form the haploid spores. The study of meiosis in plants can be done in young flower buds.

Process of meiosis : Meiosis is completed in two steps, meiosis I and meiosis II

Meiosis-I: In which the actual chromosome number is reduced to half. Therefore, meiosis I is also known as reductional division or heterotypic division. It results in the formation of two haploid cells from one diploid cell. It is divided into two parts, karyokinesis I and cytokinesis I.

Karyokinesis-I: It involves division of nucleus. It is divided into four phases *i.e.*, prophase, metaphase, anaphase, telophase.

(1) **Prophase-I**: It is of longest phase of karyokinesis of meiosis. It is again divisible into five subphases *i.e.*, leptotene, zygotene, pachytene, diplotene and diakinesis.

(i) Leptotene/Leptonema

- (a) Chromosomes are long thread like with chromomeres on it.
- (b) Volume of nucleus increases.
- (c) Chromatin network has half chromosomes from male and half from female parent.
- (d) Chromosome with similar structure are known as homologous chromosomes.
- (e) Leptonemal chromosomes have a definite polarization and forms loops whose ends are attached to the nuclear envelope at points near the centrioles, contained within an aster. Such peculiar arrangement is termed as bouquet stage (in animals) and syndet knot (in plants).
- (g) Lampbrush chromosome found in oocyte of amphibians is seen in leptotene.

(ii) Zygotene/Zygonema

- (a) Pairing or "synapsis" of homologous chromosomes takes place in this stage.
- (b) Paired chromosomes are called bivalents, which by furthur molecular packing and spiralization becomes shorter and thicker.
- (c) Pairing of homologous chromosomes in a zipper-fashion. Number of bivalents (paired homologous chromosomes) is half to total number of chromosomes in a diploid cell. Each bivalent is formed of one paternal and one maternal chromosome (i.e., one chromosome derived from each parent).
- (d) Under EM, a filamentous ladder like nucleoproteinous complex, called synaptinemal. Synaptinemal complex is seen between the homologous chromosomes which was discovered by "Moses" (1956).

(iii) Pachytene/Pachynema

- (a) In the tetrad, two similar chromatids of the same chromosome are called sister chromatids and those of two homologous chromosomes are termed non-sister chromatids.
- (b) Crossing over i.e., exchange of segments between nonsister chromatids of homologous chromosome occurs at this stage.

It takes place by breakage and reunion of chromatis segments. Breakage called nicking, is assisted by an enzyme endonuclease and reunion termed annealing is added by an enzyme ligase. Breakage and reunion hypothesis proposed by *Darlington* (1937).

- (c) Chromatids of pachytene chromosome are attached with centromere.
- (d) A tetrad consists of two sets of homologous chromosomes each with two chromatids. Each tetrad has four kinetochore (two sister and two homologous).

UNIVERSAL BOOK DEPOT 1960

(e) A number of electron dense bodies about 100 nm in diameter are seen at irregular intervals within the centre of the synaptonemal complex, known as recombination nodules.

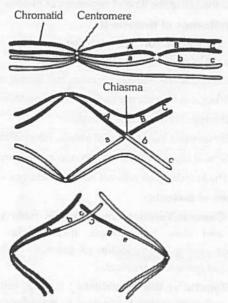

Fig: 3.3-4 Crossing over during meiosis

(f) DNA polymerase is responsible for the repair synthesis.

(iv) Diplotene/Diplonema

- (a) At this stage the paired chromosomes begin to separate (desynapsis). Terminalisation starts.
- (b) Cross is formed at the place of crossing over between non-sister chromatids.
- (c) Homologous chromosomes move apart they remain attached to one another at specific points called chiasmata.
 - (d) At least one chiasma is formed in each bivalent.
- (e) Chromosomes are attached only at the place of chiasmata.
- (f) Chromatin bridges are formed in place of synaptonemal complex on chiasmata.
 - (g) This stage remains as such for long time.

(v) Diakinesis

- (a) Terminalization completes.
- (b) Nuclear membrane and nucleolus degenerates.
- (c) Chromosome recondense and tetrad moves to the metaphase plate.
 - (d) Formation of spindle.
- (e) Bivalents are irregularly and freely scattered in the nucleocytoplasmic matrix.

When the diakinesis of prophase-I is completed than cell enters into the metaphase-I.

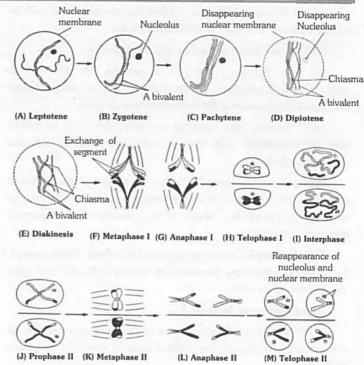

Fig: 3.3-5 Different stages of meiotic cell division (meiosis)

(2) Metaphase-I

- (i) Chromosome come on the equator.
- (ii) Bivalents arrange themselves in two parallel equatorial or metaphase plates. Each equatorial plate has one genome.
- (iii) Centromeres of homologous chromosomes lie equidistant from equator and are directed towards the poles while arms generally lie horizontally on the equator.
- (iv) Each homologous chromosome has two kinetochores and both the kinetochores of a chromosome are joined to the chromosomal or tractile fibre of same side.

(3) Anaphase-I

- (i) It involves separation of homologous chromosomes which start moving opposite poles so each tetrad is divided into two daughter dyads. So anaphase-I involves the reduction of chromosome number, this is called *disjunction*.
- (ii) The shape of separating chromosomes may be rod or J or V-shape depending upon the position of centromere.
- (iii) Segregation of Mendelian factors or independent assortment of chromosomes take place. In which the paternal and maternal chromosomes of each homologous pair segregate during anaphase-I which introduces genetic variability.

(4) Telophase-I

- (i) Two daughter nuclei are formed but the chromosome number is half than the chromosome number of mother cell.
 - (ii) Nuclear membrane reappears.
 - (iii) After telophase I cytokinesis may or may not occur.

- (iv) At the end of Meiosis I either two daughter cells will be formed or a cell may have two daughter nuclei.
 - (v) Meiosis I is also termed as reduction division.
- (vi) After meiosis I, the cells in animals are reformed as secondary spermatocytes or secondary oocytes; with haploid number of chromosomes but diploid amount of DNA.
- (vii) Chromosomes undergo decondensation by hydration and despiralization and change into long and thread like chromation fibres.

Interphase : Generally there is no interphase between meiosis-I and meiosis-II. A brief interphase called interkinesis, or intrameiotic interphase. There is no replication chromosomes, during this interphase.

Cytokinesis-I: It may or may not be present. When present, it occurs by cell-furrow formation in animal cells and cell plate formation in plant cells.

Significance of meiosis-I

- (1) It separates the homologous chromosomes to reduce the chromosome number to the haploid state, a necessity for sexual reproduction.
- (2) It introduces variation by forming new gene combinations through crossing over and random assortment of paternal and maternal chromosomes.
- (3) It induces the cells to produce gametes for sexual reproduction or spores for asexual reproduction.

Meiosis-II: It is also called equational or homotypical division because the number of chromosomes remains same as after meiosis-I. It is of shorter duration than even typical mitotic division. It is also divisible into two parts, Karyokinesis-II and Cytokinesis-II.

Karyokinesis-II: It involves the separation of two chromatids of each chromosome and their movement to separate cells. It is divided in four phases i.e., Prophase-II, Metaphase-II. Anaphase-II and Telophase-II.

Almost all the changes of Karyokinesis-II resembles to mitosis which involves.

- (1) It starts just after end of telophase I.
- (2) Each daughter cell (nucleus) undergoes mitotic division.
- (3) It is exactly similar to mitosis.
- (4) At the end of process, cytokinesis takes place.
- (5) Four daughter cells are formed after completion.
- (6) The sister kinetochores of one chromosome are separated.
- (7) The four daughter cells receive one chromatid each of the tetravalent.
 - (8) Centromere split at anaphase II.
 - (9) Spindle fibres contract at prophase II.

Cytokinesis-II: It is always present and occurs by cell furrow formation in animal cell and cell plate formation in plant cell.

So by meiosis, a diploid parental cell divides twice forming four haploid gametes or sex cells, each having half the DNA amount than that of the parental cell and one-fourth of DNA present in the cell at the time of beginning of meiosis.

Significance of meiosis-II

- Constancy of chromosome number in successive generation is brought by process.
 - (2) Chromosome number becomes half during meiosis.
 - (3) It helps in introducing variations and mutation.
 - (4) It brings about gamete formation.
 - (5) It maintains the amount of genetic informative material.
 - (6) Sexual reproduction includes one meiosis and fusion.
 - (7) The four daughter cells will have different types of chromatids.

Types of meiosis

- (1) Gametic/Terminal meiosis: In many protozoans, all animals and some lower plants, meiosis takes place before fertilization during the formation of gametes. Such a meiosis is described as gametic or terminal.
- (2) Zygotic or Initial meiosis: In fungi, certain protozoan groups, and some algae fertilization is immediately followed by meiosis in the zygote, and the resulting adult organisms are haploid. Such a meiosis is said to be zygotic or initial. This type of life cycle with haploid adult and zygotic meiosis is termed the haplontic cycle.

(3) Sporogenetic / Intermediate meiosis

- (i) Diploid sporocytes or spore mother cells of sporophytic plant, undergo meiosis to form the haploid spores in the sporangia.
- (ii) Haploid spore germinates to form haploid gametophyte which produces the haploid gametes by mitosis.
- (iii) Haploid gametes fuse to form diploid zygote which develops into diploid sporophyte by mitotic divisions. e.g., In higher plants like pteridophytes, gymnosperms and angiosperms.

Table : 3.3-2
Where does meiosis take place in different plant

Plant	Stage at which meiosis occurss			
Chlamydomonas (alga)	In zygote			
Ulothrix (alga)	In zygospore			
Spirogyra (alga)	In zygospore			
Rhizopus or Bread mould (fungus)	In zygospore			
Saccharomyces or Yeast (fungus)	During formation of ascospores in ascus mother cell or ascus			
Riccia. Marchantia, Funaria, etc. (Bryophytes)	In spore mother cell inside capsule of sporophyte.			
Ferns (Pteridophytes)	In spore mother cell inside sporangium			
Gymnosperms (e.g., Cycas, Pinus, etc.)	In microspore mother cells and megaspore mother cells inside			
Angiosperms (Wheat, pea, etc.)	Microsporangia and megasporangia during formation of microspores (pollens) and megaspores.			

Table : 3.3-3 Differences between Mitosis and Mejosis

	n Mitosis and Meiosis
Mitosis	Meiosis
General	
This division takes place in all kinds of cells and may continue throughout life.	It usually occurs in reproductive cells just before formation o gametes or spores in the life cycle of a plant
Nucleus undergoes a single division at the completion of division cycle. Similar is the case with chromosomes.	Nucleus undergoes two divisions first is reductional while second is equational, at the completion or division cycle, while the chromosomes divide only once i.e., in anaphase II.
Two daughter cells are formed at the end of mitosis	Four daughter cells are formed at end.
The chromosome no. remains constant in daughter cells like parent cell, i.e., daughter cells are genetically identical to parent cell.	The chromosome no. is reduced to half in daughter cells as compared to parent cells, <i>i.e.</i> , daughter cells are genetically different from parent cell.
Mitosis is much shorter.	Meiosis is much longer.
Mitosis may occur in diploid or haploid cells.	Meiosis always occurs in diploid cells (meiocytes).
Prophase	
Prophase is short and is without sub-stages.	Prophase 1 is prolonged with 5 different sub-stages as leptotene, zygotene, pachytene, diplotene and diakinesis.
There is no pairing of homologous chromosomes (synapsis) and hence no chance of crossing over and chiasmata formation.	Homologous chromosomes pair during zygotene sub-stage of prophase 1 and often undergo crossing over and hence forming chiasmata.
No synaptonemal complex (SC) is formed between chromosomes.	Synaptonemal complex (tripartite protein framework) is formed between pairing homologous chromosomes.
The chromosomes are ongitudinally split into two sister chromatids during early prophase, i.e., prophase chromosomes appear double from the very begining.	The chromosomes are not longitudinally split but appear as single thread, <i>i.e.</i> , prophase I chromosomes do not appear double in the beginning.
Chromosomes do not unfold and there is no transcription and protein synthesis in prophase.	Chromosomes unfold and there may occur transcription and protein synthesis during diplotene sub-stage of prophase I.
Metaphase	
All chromosomes form a single plate in metaphase.	Chromosomes form 2 parallel plates in metaphase I and one

plate in metaphase II.

metaphase of mitosis.

On equatorial plate, chromosomes

appear four threaded in metaphase

I, while metaphase II is similar to

On

chromosomes

threaded

equatorial

plate,

two

Anaphase	
Splitting of centromere of chromosomes and hence separation of 2 chromatids of each chromosome occurs at anaphase.	There is no splitting of centromeres in anaphase I and there is separation of homologous chromosomes in anaphase I. In anaphase II, splitting of centromeres and hence separation of chromatids occurs.
Telophase	
Telophase occurs in all cases.	In some cases, telophase I is omitted.
Daughter cells have same number of chromosomes as parent cell.	At the end of telophase I, chromosome number is reduced to half.
Cytokinesis	
Karyokinesis (division of nucleus) is usually followed by cytokinesis (wall formation).	Sometimes cytokinesis does not occur after telophase I or meiosis. I but it always occurs after meiosis II or telophase II, thus forming 4 cells simultaneously.
Significance	
Mitosis is responsible for growth, repair and healing.	Meiosis is responsible for maintaining chromosomes number constant from generation to generation, forms gametes or spores and also produces variations due to crossing over.

Tips & Tricks

- ✓ Interkinesis: Stage between meiosis I and meiosis II.
- Mitosis index is the ratio of dividing and non-dividing cells.
- Karyochoriosis: A type of mitosis in fungi in which is intranuclear nucleus divides by furrow formation.
- In mitosis, plectonemic coiling takes place, in which sister chromatids are tightly coiled upon each other and are not easily separable. Paranemic coiling found in meiosis.
- Brachymeiosis: Failure of meiosis-II. It is characteristic feature of fungi.
- E Chiasmata first observed by Janssens (1909).
- To study mitosis root tips are fixed in 1: 3 acetic acid and methanol.
- Mitotic crossing over takes place in parasexual cycle.
- Cell cycle duration − 20 minutes in bacteria, 20 hours in root tip of onion. 2-3 hrs in yeast, 24- hrs man.

Ordinary Thinking

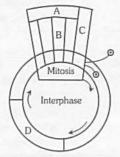

Objective Questions

Cell division

- 1. The term "meiosis" was coined by
 - (a) Hertwig and Van Bevedin
 - (b) Sutton and Boveri
 - (c) Hofmeister and Waldever
 - (d) Farmer and Moore
- 2. Coiling of chromatids in mitotic and meiotic division is

[MP PMT 2002]

- (a) Paranemic in both
- (b) Plectonemic in both
- (c) Paranemic in mitosis and plectonemic in meiosis
- (d) Plectonemic in mitosis and paranemic in meiosis
- Given below is a schematic break-up of the phases/stages of cell cycle

Which one of the following is the correct indication of the stage/phase in the cell cycle [CBSE PMT 2009]

- (a) B-Metaphase
- (b) C-Karyokinesis
- (c) D-Synthetic phase
- (d) A-Cytokinesis
- 4. Condensation of chromosomes occurs in [AFMC 2002]
 - (a) Prophase I
- (b) Prophase II
- (c) Anaphase
- (d) Metaphase
- Find the correctly matched pairs and choose the correct option
 - A. Leptotene
- The chromosomes become
- invisible
- B. Zygotene
- Pairing of homologous
- C. Pachytene
- chromosomes

 Dissolution of the
 - synaptonemal complex takes
 - place
- D. Diplotene
- Bivalent chromosomes appear as tetrads
- E. Diakinesis
- Terminalization of chiasmata takes place

[AFMC 1995; Odisha JEE 2012; Kerala PMT 2012]

- (a) A and B are correct
- (b) B and D are correct
- (c) B and E are correct
- (d) B and C are correct
- (e) C and D are correct
- The role of meiosis

- [AFMC 2002]
- (a) Formation of gametes(c) Bringing diplophase
- (b) Bringing haplophase(d) Completing life cycle

- Which of the following events are not characteristic features of telophase
 - A. Chromosome material condenses to form compact mitotic chromosomes
 - B. Nucleolus, Golgi complex and ER reform
 - C. Nuclear envelope assembles around the chromosome clusters
 - D. Centromeres split and chromatids separate
 - Chromosomes cluster at opposite, spindle poles and their identity as discrete elements is lost

[Kerala PMT 2012]

- (a) A, B and D only
- (b) A and D only
- (c) B and C only
- (d) C, D and E only
- (e) A and B only
- 8. Which stage connecting link between Meiosis I and Meiosis II

[AFMC 2002; Kerala PMT 2011]

- (a) Interphase I
- (b) Interphase II
- (c) Interkinesis
- (d) Anaphase I
- Which of the following stage is affected by colchicum [BVP 2001; AFMC 2002; Pb. PMT 2004; Odisha JEE 2011]

Or

Spindle apparatus is formed during which stage of mitosis

- [AFMC 1999]
- (a) Metaphase
- (b) Prophase
- (c) Interphase
- (d) Anaphase
- 10. "G₀" state of cells in eukaryotic cell cycle denotes

[AIEEE Pharmacy 2003]

- (a) Check point before entering the next phase
- (b) Pausing in the middle of a cycle to cope with a temporary delay
- (c) Death of a cell
- (d) Exit of cells from cell cycle
- 11. Three copies of chromosome 21 in a child with Down's syndrome have been formed analysed using molecular biology technology to detect any possible DNA polymorphism with reference to different alleles located on chromosome 21. Results showed that out of 3 copies 2 of the chromosomes of the child contain the same alleles as one of the mother's alleles. Based on this when did the non-disjunction event most likely occur [KCET 2015]
 - (a) Paternal meiosis I
- (b) Maternal meiosis I
- (c) Paternal meiosis II
- (d) Maternal meiosis II
- 12. Mitosis occurs in
- [RPMT 2002]
 (b) Diploid individuals
- (a) Haploid individuals(c) Both (a) and (b)
- (d) In bacteria only
- 13. Which is not true for anaphase
- e [Odisha JEE 2004]
 - (a) Golgi body and ER are reformed
 - (b) Chromosomes move to opposite poles
 - (c) Spindle poles move farther apart
 - (d) Centromeres split and chromatids separate
- 14. Cyclin is associated with which one of the following

[BHU 2000]

Or

Diploid living organism develops from zygote by repeated cell divisions is called [J & K C CET 2005]

- (a) Glycolysis
- (b) Cyclosis
- (c) Haemolysis
- (d) Mitosis

- 15. For viewing diakinesis which one of the following would be a suitable material [MP PMT 2002] (a) Onion root tip
- (b) Leaf of Dichanthium
- (c) Rat tail
- (d) Flower bud
- Which is not the character of mitosis
 - [MP PMT 2000]
 - (a) Leptotene (c) Pachytene
- (b) Zygotene (d) All of the above
- 17. Synaptonemal complex is formed during [CBSE PMT 2001]
 - (a) Meiosis
- (b) Amitosis
- (c) Mitosis
- (d) Cytokinesis
- Synaptonemal complex was discovered in (a) 1956

 - (c) 1935
- (b) 1950
- (d) 1980
- 19. Recombinant nodules are found during which of the following [BHU 2000]
 - (a) Anaphase
- (b) Prophase
- (c) Telophase
- (d) Metaphase
- 20. Four daughter cells formed after meiosis are [MP PMT 2001]
 - (a) Genetically similar
- (b) Genetically different
- (c) Anucleate
- (d) Multinucleate
- 21. The term synaptonemal complex refers to site of

[BHU 2012]

[BHU 2000]

- (a) Chromatid separation
- (b) Spindle attachment
- (c) Replication
- (d) Chromosome alignment and recombination
- 22. Repulsion of homologous chromosomes takes place in

[MP PMT 2001]

- (a) Zygotene
- (b) Leptotene
- (c) Diakinesis
- (d) Diplotene
- 23. Which cell division is found during cleavage [RPMT 2001]
 - (a) Amitosis
- (b) Mitosis
- (c) Closed mitosis
- (d) Meiosis
- A stage in mitosis that starts towards the middle of anaphase and is completed with the telophase is [AFMC 2012]

Or

Division of cytoplasm after completion of nuclear division is called [MP PMT 2012]

- (a) Cytokinesis
- (b) Karyokinesis
- (c) Crossing over
- (d) Interkinesis
- How many ATP is required during anaphase to move chromosomes from equator to the poles [BHU 2000]
 - (a) 38 ATP
- (b) 5 ATP
- (c) 30 ATP
- (d) 76 ATP
- 26. Mitosis is the process by which eukaryotic cells

[Pune CET 1998; CBSE PMT 2000; BHU 2000]

- (a) Expose the genes for protein synthesis
- (b) Become specialized in structure and function
- (c) Multiply
- (d) Grow
- In pachytene stage of meiosis the chromosomes appear

[MP PMT 1994; BHU 2002; Kerala PMT 2010]

- (a) Single stranded
- (b) Double stranded
- (c) Three stranded
- (d) Four stranded

- Microtubule depolymerizing drug such as colchicine is expected to [AIIMS 2012]
 - (a) Inhibit spindle formation during mitosis
 - (b) Inhibit cytokinesis
 - (c) Allow mitosis beyond metaphase
 - (d) Induce formation of multiple contractile rings
- Recombination of genes occur at

[J & K CET 2002]

[KCET 1998]

- (a) Prophase in mitosis
- (b) Prophase I in meiosis

- (c) Prophase II in meiosis 30.
- (d) Metaphase II in meiosis
- The second division in meiosis is called (a) Equational division
 - (b) Reduction division
 - (c) Multiplied division
- (d) None of the above
- Which stages of cell division do the following figures A and B represent respectively [NCERT; CBSE PMT (Pre.) 2010]

- (a) Prophase Anaphase
- (b) Metaphase Telophase
- (c) Telophase Metaphase
- (d) Late Anaphase Prophase
- 32. Select correct option

Why	PARTIES OF THE		I
(A)	Synapsis aligns homologous chromosomes	(i)	Anaphase-II
(B)	Synthesis of RNA and protein	(ii)	Zygotene
(C)	Action of enzyme recombinase	(iii)	G ₂ -phase
(D)	Centromeres do not separate but chromatids move towards opposite poles	(iv)	Anaphase-I

- 33. Which of the following statements is incorrect about Go phase [AIIMS 2012]
 - (a) Mitosis occurs after Go phase
 - (b) Biocatalysts can be used to exit Go phase
 - (c) Cell volume keeps on increasing during this phase
 - (d) Cell metabolism occurs continuously in G_0 phase

A somatic cell that has just completed the S-phase of its cell cycle, as compared to gamete of the same species, has

[AIPMT (Cancelled) 2015]

- (a) Same number of chromosomes but twice the amount of
- (b) Twice the number of chromosomes and four times the amount of DNA
- (c) Four time the number of chromosomes and twice the amount of DNA
- (d) Twice the number of chromosomes and twice the amount of DNA
- 35. Arrange the following events of meiosis in correct sequence
 - (A) Crossing over
 - (B) Synapsis
 - (C) Terminalisation of chiasmata
 - (D) Disappearance of nucleolus

[AIPMT 2015]

- (a) (B), (A), (C), (D)
- (b) (A), (B), (C), (D)
- (c) (B), (C), (D), (A)
- (d) (B), (A), (D), (C)
- In Which stage of meiosis crossing over takes place 36.

[Odisha JEE 2009]

- (a) Prophase 1
- (b) Prophase
- (c) Metaphase
- (d) Anaphase
- Beads on string like structures of A are seen in B, which 37. further condense to form chromosomes in C stage of cell [AIIMS 2012] division. What are A, B and C

	A	В	C
(a)	Chromonema	Chromatin	Metaphase
(b)	Chromatin	Chromatid	Metaphase
(c)	Chromonema	Chromosome	Anaphase
(d)	Chromonema	Chromatid	Anaphase

The best stage to count the number of chromosomes during 38. mitosis is or structure of chromosomes can be best seen at

[CPMT 2000; BHU 2001; CBSE PMT 2004; J & K CET 2008; MP PMT 2010]

In which phase of mitosis the chromosomes are arranged around the equator of the spindle

[Manipal MEE 1995; CPMT 1998; Kerala CET 2002; BVP 2002; RPMT 2005; MP PMT 2009]

- (a) Prophase

 - (a) Prophase-I
- (b) Metaphase-I
- (c) Anaphase-I
- (d) Anaphase-II

During interphase, RNA and proteins are synthesized in 42.

[MP PMT 1997]

- (a) S phase
- (b) G₁ phase
- (c) G2 phase
- (d) In both G₁ and G₂ phases
- 43. Four chromatids and two centromeres which [CPMT 1995] homologous occurs in
 - (a) Zygotene
- (b) Diplotene
- (c) Diakinesis
- (d) Pachytene
- The number of chromosome groups at the equatorial plate in metaphase–I of meiosis in a plant with 2n = 50 shall be

[MP PMT 1995, 98]

(a) 50

(b) 25

(c) 30

- (d) 100
- The significance of meiosis lies in

[NCERT; MP PMT 1995, 98; BVP 2003]

- (a) Reduction of the diploid number of chromosomes to haploid
- (b) Maintaining constancy in the number of diploid chromosomes during sexual reproduction
- Production of genetic variability in the population of a species
- (d) All the above
- During which phase(s) of cell cycle amount of DNA in a cell remains at 4C level if the initial amount is denoted as 2C

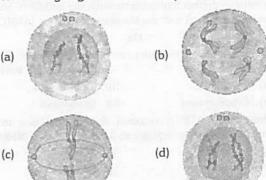

[CBSE PMT 2014]

- (a) Only G₂
- (b) G₂ and M
- (c) Go and G1
- (d) G₁ and S
- The given figure represent a sequence in cell division

The missing stage in the above sequence is

[NCERT]

Identify the meiotic stage in which the homologous chromosomes separate while the sister chromatids remain associated at their centromeres

Odisha JEE 2009; CBSE PMT (Mains) 2012; PET (Pharmacy) 2013]

Or

In which stage of meiosis homologous chromosomes are [WB JEE 2016] segregated

- (a) Metaphase I
- (b) Metaphase II
- (c) Anaphase I
- (d) Anaphase II

Which phase comes in between the G_1 and G_2 phase of [WB JEE 2010]

The formation of chromatid takes place in[Odisha JEE 2011]

- (a) M-phase
- (b) G_0 phase
- (c) S-phase
- (d) Interphase
- 50. During mitosis ER and nucleolus begin to disappear at

[AFMC 1996; CBSE PMT (Pre.) 2010]

- (a) Early prophase
- (b) Late prophase
- (c) Early metaphase
- (d) Late metaphase
- 51. Match List I and List II and select the correct answer using the code given below in the lists:

List I (Phase of meiosis)		List II (Event that occurs)	
1.	Prophase I	Crossing over occurs	
2.	Metaphase I	Sister chromatids migrate to opposite poles	
3.	Anaphase I	Homologous line up at equator in pairs	

Code

[MP PMT 1993]

- (a) 1, 2 and 3 are correct
- (b) 1 and 2 are correct, 3 is false
- (c) 1 is correct, 2 and 3 are false
- (d) 1 and 3 are correct, 2 is false
- 52. Chromosome number is halved in meiosis during

[NCERT; RPMT 2006]

- (a) Metaphase-I
- (b) Anaphase-I
- (c) Metaphase-II
- (d) Telophase-I
- 53. Yeast cell can progress through the cell cycle in about

[NCERT; AMU (Med.) 2012]

- (a) 30 minutes
- (b) 60 minutes
- (c) 90 minutes
- (d) 120 minutes
- Normal cellular activities, such as protein synthesis occur 54. primarily during [Pune CET 1998]

Or

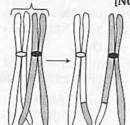

Chromosome replicate in which stage of meiosis

[MP PMT 1994;

BHU 2002; WB JEE 2008; Odisha JEE 2008]

- (a) Interphase
- (b) Anaphase
- (c) Metaphase
- (d) Prophase
- 55. Given below is the representation of a certain event at a particular stage of a type of cell division. Which is this stage

[NCERT; CBSE PMT (Pre.) 2012]

- (a) Prophase I during meiosis
- (b) Prophase II during meiosis
- (c) Prophase of Mitosis
- (d) Both prophase and metaphase of mitosis

In mitosis the movement of chromosomes requires 56.

[CPMT 1993]

- (a) Presence of centromere (b) Plasmalemma
- (c) Spindle fibres
- (d) Nucleotides
- DNA replication occurs during

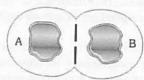

[MDAT Bihar 1995; MP PMT 2005; Odisha JEE 2010]

The replication of centrioles occurs during

[MP PMT 1994; BHU 2004; WB JEE 2016]

G1, G2 and S phases are seen in which phase of the cell cycle [AFMC 2009]

- (a) Prophase
- (b) Metaphase
- (c) Anaphase
- (d) Interphase
- (e) Leptotene
- The given diagram shows a cell

Which of the following statements related to the image is not

- (a) The nuclear envelope is disappearing
- (b) The cell furrow is forming
- (c) It is an animal cell
- (d) It is in telophase
- Meiosis is found at

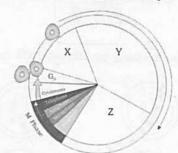

[MP PMT 2005]

- (a) Shoot apex
- (b) Reproductive part
- (c) Leaves bud
- (d) Vegetative parts
- During cell division, sometimes there will be failure of separation of sister chromatids. This event is called

[Kerala PMT 2004; WB JEE 2016]

- (a) Interference
- (b) Complementation
- (c) Coincidence
- (d) Non-disjunction
- 61. If a cell has a chromosome number after first meiosis equal to 48. The chromosome number in the daughter cells after the completion of meiosis will be [BHU 2001]
 - (a) 48
- (b) 24
- (c) 12

- (d) 36
- 62. The given diagram is of a typical cell cycle

Identify the parts labelled as X, Y and Z

- (a) $X G_1$; $Y G_2$; $Z G_0$ (b) $X G_0$; Y S; $Z G_2$
- (c) X G₂; Y S; Z G₁
- (d) X G₁; Y S; Z G₂

Chiasmata formation takes place during

[CPMT 1994, 2004; RPMT 1995; MP PMT 2002, 03, 06, 11; AMU (Med.) 2010]

- (a) Prophase I (Diplotene)
- (b) Metaphase I
- (c) Anaphase II
- (d) Telophase I
- The given figure represents various stages of cell division. 64. [NCERT] Identify them

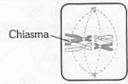

B (a) A - Metaphase I, B - Prophase, C - Anaphase

- (b) A Metaphase I, B Prophase I, C Anaphase I
- (c) A Metaphase, B Prophase I, C Anaphase I
- (d) A Metaphase, B Prophase I, C Anaphase
- During the first metaphase of meiosis the centromeres 65.
- [MP PMT 1994]
 - (a) Undergo division
- (b) Do not divide
- (c) Divide but do not separate (d) Are not identical
- During gamete formation, the enzyme recombinase participates 66. during [NCERT; CBSE PMT (Pre) 2012; CBSE PMT 2014]
 - (a) Metaphase I
- (b) Anaphase II
- (c) Prophase I (Pachytene) (d) Prophase II
- Which of the following is unique to mitosis and not a part of 67. [DUMET 2009]
 - (a) Homologous chromosomes behave independently
 - (b) Chromatids are separated during anaphase
 - (c) Homologous chromosomes pair and form bivalents
 - (d) Homologous chromosomes crossover
- The protein for spindle fibre is 68.

[AIIMS 2001; WB JEE 2011; Odisha JEE 2011]

- (a) Myosin
- (b) Actin
- (c) Troponin
- (d) Myoglobin
- 56 cells are produced in meiosis in which [Odisha JEE 2011] 69.
 - (a) First division is reductional (b) First division is equational
 - (c) Second division is reductional (d) None of these
- The given diagram of a cell undergoing meiosis, indicated 70. that crossing over occurs only at the chiasma

Which of the following gametes will NOT be formed from [NCERT] this cell

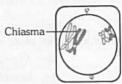

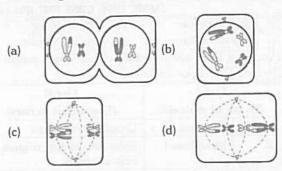

The given diagram shows a cell undergoing meiosis

Which diagram shows the next stage in the process [NCERT]

The process of mitosis is divided into 4 phases. Identify the correct order in which these phases appear in mitosis

[MP PMT 1993]

- (a) Anaphase, metaphase, telophase and prophase
- (b) Telophase, anaphase, metaphase and prophase
- (c) Metaphase, prophase, anaphase and telophase
- (d) Prophase, metaphase, anaphase and telophase
- Meiosis and mitosis differ from each other because in 73. [CPMT 1993]
 - (a) The four nuclei formed are not similar to parental ones
 - (b) Homologous chromosomes pair are exchange parts
 - (c) Number of chromosomes gets halved
 - (d) All the above
- Cell division is initiated by 74.
- [CBSE PMT 1993]

- (a) Centrosome
- (b) Centriole
- (c) Centromere
- (d) Chromomere
- 75. "Endomitosis" refers to
 - (a) Division of nucleus without chromosomal division
 - (b) Division of chromosome without nuclear division
 - (c) Division of cytoplasm
 - (d) None of the above
- The homologous chromosomes follow the process of 76. synapsis in the stage or Pairing of homologous chromosome [DPMT 1995; MP PMT 1996, 99, 2011; takes place in

RPMT 1997: BHU 2003; Haryana PMT 2005; J & K CET 2010; NEET (Karnataka) 2013]

Or

During which stage of meiosis, synaptonemal complex is [CPMT 2010; Odisha JEE 2011] formed

- (a) Leptotene
- (b) Zygotene
- (c) Diplotene
- (d) Pachytene
- At metaphase, chromosomes are attached to the spindle [NCERT; Manipal 2005; fibres by their CBSE PMT (Mains) 2011; NEET (Karnataka) 2013]
 - (a) Kinetochores
- (b) Centromere
- (c) Satellites
- (d) Secondary constrictions

(a) G1, G2, S and M

(c) G_1 , S, G_2 and M

(a) 8

(c) 32

Regarding the sequence of cell cycle, which one is correct

If we ignore the effect of crossing over, how many different haploid cells arise by meiosis in a diploid cell having 2n=12

(b) 16

(d) 64

[NCERT; MP PMT 1998; AIIMS 1999; CPMT 2002;

RPMT 2005; WB JEE 2008, 12]

(b) S, G₁, G₂, and M

(d) G2, S, G1, and M

94. What is not seen during mitosis in somatic cells

[DPMT 2006; NEET (Phase-I) 2016]

- (a) Spindle fibres
- (b) Chromosome movement
- (c) Disappearance of nucleolus
- (d) Synapsis
- 95. The given figure shows a cell undergoing in Prophase I

Keeping the diagram in view which of the following diagram is correct for one of the cell at the end of meiosis [NCERT]

96. The microtubules from opposite poles of the spindle get attached to the kinetochores of sister chromatids in

[AMU (Med.) 2009]

Or

At what phase of meiosis are there two cells, each with sister chromatids aligned at the spindle equator

[Pune CET 1998; BHU 1999]

- (a) Prophase II
- (b) Metaphase II
- (c) Anaphase II
- (d) None of these
- Prophase is longer in

[Manipal MEE 1995; CPMT 2001; MHCET 2001; WB JEE 2011]

- (a) Mitosis
- (b) Meiosis
- (c) Equal in both
- (d) Amitosis
- 98. Which of the following characters is related with telophase

[MP PMT 2009]

- (a) Formation of nuclear membrane
 - (b) Formation of nucleolus
 - (c) Elongation of chromosome
 - (d) Formation of two daughter nuclei
- 99. In which stage of cell division chromosomes are most condensed [WB JEE 2009; AIIMS 2010]
 - (a) Prophase
- (b) Metaphase
- (c) Anaphase
- (d) Telophase
- **100.** Which of the following event takes place during Diplotene stage of prophase I of meosis [DUMET 2010]
 - (a) Compaction of chromosomes
 - (b) Formation of synaptonemal complexes
 - (c) Formation of recombinational nodules
 - (d) Dissolution of synaptonemal complex
- 101. The term "mitosis" was proposed by [MP PMT 2011]
 - (a) Flemming
- (b) Farmer
- (c) Moore
- (d) Boveri

102. Root cells of wheat has 2n = 42 chromosomes. Which one of the following is the basic chromosome number of wheat

[WB JEE 2010]

- (a) 42
- (b) 21

(c) 7

- (d) 14
- 103. Which of the following structure will not be common to mitotic cell of a higher plant [CBSE PMT 1997]
 - (a) Cell plate
- (b) Centromere
- (c) Centriole
- (d) Spindle fibre
- 104. How many mitotic divisions are needed for a single cell to make 128 cells [CBSE PMT 1997; AFMC 1999, 2002;

Odisha JEE 2010]

(a) 7

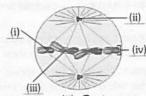

(b) 14

(c) 28

- (d) 32
- 105. Which one of the following forms the spindle apparatus during cell division [Kerala CET 2002]
 - (a) Chromosome
- (b) Centrosome
- (c) Ribosome
- (d) Chondriosome
- During cell division in apical meristem nuclear membrane reappears in [CBSE PMT 1997]
 - (a) Interphase
- (b) Telophase
- (c) Prophase
- (d) S phase
- **107.** Cell in G_0 phase of cell cycle
- (b) Enter cell cycle

[WB JEE 2009]

- (a) Exit cell cycle
 (c) Suspend cell cycle
- (d) Terminate cell cycle
- 108. How many reduction divisions are necessary for the formation of 200 grains of wheat [MHCET 2002]
 - (a) 250
- (b) 150
- (c) 200
- (d) 360
- 109. See the following figure and identify marked lines (i), (ii), (iii) and (iv) [NCERT]

- (a) (i) Chromosome, (ii) Centromere, (iii) Centriole, (iv) Chromatid
- (b) (i) Chromatid, (ii) Centromere, (iii) Centriole, (iv) Chromosome
- (c) (i) Chromosome, (ii) Centriole, (iii) Centromere, (iv) Chromatid
- (d) (i) Chromatid, (ii) Centriole, (iii) Centromere, (iv) Chromosome
- 110. The non-sister chromatids twist around and exchange segments with each other during or In meiosis crossing over is initiated at [Kerala PMT 2009; WB JEE 2011; NEET (Phase-I) 2016]
 - (a) Diplotene
- (b) Diakinesis
- (c) Leptotene
- (d) Pachytene
- (e) Zygotene

UNIVERSAL BOOK DEPOT 1960

 During mitosis chromosomes go to their poles in a stage called [CPMT 1994; MP PMT 2001; DPMT 2003; BHU 2004]

The shape of chromosome is clearly visible at

[Odisha JEE 2009]

- (a) Prophase
- (b) Metaphase
- (c) Anaphase
- (d) Telophase
- 112. The number of mitotic cell division required to produce 256 cells from single cell would be [KCET 2007]
 - (a) 10

(b) 12

(c) 6

- (d) 8
- 113. DNA replication takes place in

[MP PMT 2009; AFMC 2010; WB JEE 2016]

DNA molecule of each chromosome become double in

[NCERT; CPMT 1996, 2001, 10;

MP PMT 1994, 99, 2001, 02, 06, Kashmir MEE 1995; CBSE PMT 1996, 2001; RPMT 1997; Pb. PMT 1999; Kerala PMT 2006]

Or

DNA and histone proteins are synthesized during the following phase of cell cycle

[DPMT 2004; CBSE PMT 2005; NEET (Phase-II) 2016]

- (a) G₁ phase
- (b) G₂ phase
- (c) S phase
- (d) Mitotic phase
- 114. During the meiotic division the

[BHU 2005]

- (a) Homologous chromosomes are separated
 - (b) The linkage is disturbed
 - (c) The homologous chromosomes do not segregate
 - (d) All of the above
- 115. The number of chromosomes after I phase of meiotic division in reduction division [CPMT 1994]
 - (a) Remain unchanged
- (b) Become doubled
- (c) Become halved
- (d) None of the above
- 116. Meiosis can be observed in

[MP PMT 1992, 96; CPMT 1994; WB JEE 2008]

- (a) Root tips
- (b) Cambium
- (c) Anther (PMC)
- (d) Pollen grains
- 117. Select the correct match

A.	S phase	-	DNA replication
B.	Zygotene	-	Synapsis
C.	Diplotene	-	Crossing over
D.	Meiosis	1	Both haploid and diploid cells
E.	Gap 2 phase	-	Quiescent stage

[Kerala PMT 2011]

- (a) A and B
- (b) C and D
- (c) C and E
- (d) A, C and E
- (e) A and D
- 118. During meiosis, the alleles of the parental pair separate or segregate from each other. How many allele(s) are then transmitted to a gamete [Kerala PMT 2011]
 - (a) Four
- (b) Two
- (c) Six
- (d) One
- (e) Eight

119. In meiosis I, a bivalent is an association of

[NCERT; Kerala PMT 2007]

- (a) Four chromatids and four centromeres
- (b) Two chromatids and two centromeres
- (c) Two chromatids and one centromere
- (d) Two chromatids and four centromeres
- (e) Four chromatids and two centromeres
- 120. Cell division can not be stopped in which phase of the cell cycle [WB JEE 2010]
 - (a) G_1 phase
- (b) G_2 phase
- (c) S- phase
- (d) Prophase
- 121. Cell plate is referred as
- [MP PMT 1994; MHCET 2001; JIPMER 2002; Odisha JEE 2004]
- (a) Germplast
- (b) Idioblast
- (c) Phragmoplast
- (d) Middle lamella
- 122. In which phase proteins for spindle fibre formation are synthesized [Odisha JEE 2004]
 - (a) G₁ phase
- (b) G₂ phase
- (c) S-phase
- (d) Anaphase
- 123. Karyokinesis differ from cytokinesis because it involves

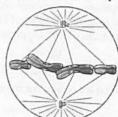

[MP PMT 1994, 2003]

[DPMT 2007]

- (a) Division of cytoplasm
- (b) Division of the nucleus and cytoplasm
- (c) Division of the nucleus
- (d) Division of the cell
- 124. Differentiated cell arrests at which stage
 - (a) G₁
- (b) H₂
- (c) G₀
- (d) U
- 125. The nuclear membrane disappears in

[CPMT 1993; MP PMT 1995, 98; J & K CET 2002]

- (a) Metaphase
- (b) Early prophase
- (c) Late prophase
- (d) Anaphase
- 126. Chromonemata start associating into bivalent chromosomes during [MP PMT 1997; J & K CET 2002]
 - (a) Zygotene
- (b) Leptotene
- (c) Pachytene
- (d) Diplotene
- 127. Select the correct option with respect to mitosis

[CBSE PMT (Pre.) 2011; NEET (Karnataka) 2013]

- (a) Chromosomes move to the spindle equator and get alingned along equatorial plate in metaphase
- (b) Chromatids separate but remain in the centre of the cell in anaphase
- (c) Chromatids start moving towards opposite poles in telophase
- (d) Golgi complex and endoplasmic reticulum are still visible at the end of prophase

128.	Which	one	of	the	following	precedes	re-formation	of	the	
	nuclea	renv	elop	oe d	uring M ph	ase of the	cell cycle			

INCERT; CBSE PMT 2004; AIIMS 2008]

- (a) Formation of the contractile ring, and formation of the phragmoplast
- (b) Formation of the contractile ring, and transcription from chromosomes
- (c) Decondensation of chromosomes, and reassembly of the nuclear lamina
- (d) Transcription from chromosomes, and ressembly of the nuclear lamina
- 129. In an organism, if the normal diploid number of chromosomes is 8, how many chromatids are present in each daughter cell at the end of meiosis I [MP PMT 1993]
 - (a) 2

(b) 4

(c) 8

(d) 16

130. In eukaryotic cell cycle, cell fusion experiments show that

[AIEEE Pharmacy 2004]

- (a) When an S-phase cell is fused with a G₁-phase cell, G₁-phase cell is stimulated to synthesize DNA
- (b) When an S-phase cell is fused with a G_2 -phase cell, DNA synthesis is induced in G_2 -phase cell.
- (c) When a G₁-phase cell is fused with a G₂-phase cell, DNA synthesis is induced in both G₁ and G₂ phase cells
- (d) When a G_1 -phase cell is fused with an M-phase cell both G_1 and M phase cells are stimulated to synthesise DNA
- **131.** The points at which crossing over has taken place between homologous chromosomes are called

[Pune CET 1998; BHU 2001]

O

Visible expression of the genetic phenomenon of crossing over is called [KCET 2012]

- (a) Protein axis
- (b) Synaptonemal complexes
- (c) Chiasmata
- (d) Centromeres
- 132. How many meiotic division would be required to produce 101 female gametophytes in an angiosperm [Pb. PMT 1997]
 - (a) 101
- (b) 26
- (c) 127
- (d) None of these
- 133. Mitotic spindle have main protein [BHU 2006; MP PMT 2007]
 - (a) Tubulin
- (b) Myosin
- (c) Tropomyocin
- (d) Dynein
- 134. Cells of certain species of animals have six pairs of chromosomes. How many molecules of DNA will remain in a nucleus of these animals during G_2 phase [WB JEE 2016]
 - (a) 12

(b) 48

(c) 6

- (d) 24
- 135. Which of the following is not true for meiosis

[WB JEE 2016]

- (a) Production of genetic variability
- (b) Maintaining constancy of chromosome number during sexual reproduction
- (c) Reduction of chromosome number to one half
- (d) Production of diploid cell
- **136.** Which of the following is used as the mitotic spindle poison

[WB JEE 2016]

- (a) Ca++
- (b) Mg++
- (c) Tubulin
- (d) Colchicine

- 137. Progression of cell cycle is regulated by the concentration of which type of molecule [WB JEE 2016]
 - (a) Centrosomes

(b) Cyclin-dependent kinases

(c) Cyclins

- (d) Microtubules
- **138.** When cell has stalled DNA replication fork, which checkpoint should be predominantly activated

[NEET (Phase-II) 2016]

- (a) Both G₂/M and M
- (b) G₁/S
- (c) G₂/M
- (d) M
- 139. Match the stages of meiosis in Column-I to their characteristic features in Column-II and select the correct option using the codes given below [NEET (Phase-II) 2016]

Column-I

Column-II

- (A) Pachytene
- (i) Pairing of homologous chromosomes
- (B) Metaphase I
- (ii) Terminalization of chiasmata
- (C) Diakinesis
- (iii) Crossing-over takes
- (D) Zygotene
- (iv) Chromosomes align at equatorial plate

Codes	(A)	(B)	(C)	(D)
(a)	(iv)	(iii)	(ii)	(i)
(b)	(iii)	(iv)	(ii)	(i)
(c)	(i)	(iv)	(ii)	(iii)
(d)	(ii)	(iv)	(iii)	(i)

- 140. Anaphase promoting Complex (APC) is a protein degradation machinery necessary for proper mitosis of animal cells. If APC is defective in a human cell, which of the following is expected to occur [NEET 2017]
 - (a) Chromosomes will not condense
 - (b) Chromosomes will be fragmented
 - (c) Chromosomes will not segregate
 - (d) Recombination of chromosome arms will occur
- **141.** Which of the following options gives the correct sequences of events during mitosis [NEET 2017]
 - (a) Condensation → nuclear membrane disassembly → crossing over → segregation → telophase
 - (b) Condensation → nuclear membrane disassembly → arrangement at equator → centromere division → segregation → telophase
 - (c) Condensation → crossing over → nuclear membrane disassembly → segregation → telophase
 - (d) Condensation → arrangement at equator → centromere division → segregation → telophase

Q NCERT Exemplar Questions

- Select the correct statement about G 1 phase
- [NCERT]
- (a) Cell is metabolically inactive
- (b) DNA in the cell does not replicate
- (c) It is not a phase of synthesis of macromolecules
- (d) Cell stops growing

At which stage of meiosis कवमे the genetic constitution of gametes is finally decided [NCERT] (a) Metaphase I (b) Anaphase II

(c) Metaphase II

(d) Anaphase I

Meiosis occurs in organisms during 3.

[NCERT]

[NCERT]

Sexual reproduction

Vegetative reproduction

Both sexual and vegetative reproduction

(d) None of the above

During anaphase-I of meiosis 4.

Homologous chromosomes separate Non-homologous autosomes separate

Sister chromatids separate

(d) Non-sister chromatids separate

5. Mitosis is characterised by

[NCERT]

(a) Reduction division

(b) Equal division

(c) Both reduction and equal division

(d) None of the above

6. Identify the wrong statement about meiosis [NCERT]

(a) Pairing of homologus chromosomes

(b) Four haploid cells are formed

(c) At the end of meiosis the number of chromosomes are reduced to half

(d) Two cycle of DNA replication occurs

7. Cells which are not dividing are likely to be at [NCERT]

(a) G1

(b) G2

Go (d) S phase 8.

Which of the events listed below is not observed during [NCERT]

(a) Chromatin condensation

(b) Movement of centrioles to opposite poles

Appearance of chromosomes with two chromatids joined together at the centromere.

(d) Crossing over

Critical Thinking

Objective Questions

1. Pick out the correct statements

> (A) Mitosis takes place in the somatic cells and meiosis takes place in the germ cells

> (B) During mitosis, the DNA replicates once for one cell division and in meiosis the DNA replicates twice for two cell divisions

(C) Mitosis and meiosis occur both in sexually and asexually reproducing organisms [Kerala PMT 2008]

(a) (A) only

(b) (B) only

(c) (C) only

(d) (A) and (B) only

(e) (B) and (C) only

2. The number of DNA in chromosome at G_2 stage of cell cycle [RPMT 2002]

(a) One

(b) Two

(c) Four (d) Eight

3. While working in a lab, a student forgot to add colchicine while karyotyping through blood culture technique, Then what will happen [GUJCET 2014]

(a) Mitosis will be arrested at metaphase

(b) Chromosomal division will continue and each chromosome will have four arms

(c) Chromosomal division will continue

(d) Mitosis will be arrested at telophase

Which one of the following pairs is correctly matched

[MP PMT 1993]

(a) Anaphase I Homologous chromosomes separated

(b) Metaphase I Pairing of maternal and paternal homologous chromosomes takes place

(c) Interphase A nuclear envelope encloses each haploid set of chromosomes

(d) Prophase I Non-homologous chromosomes are separated

5. Chromosome start separating at which stage of mitosis

[AFMC 1996]

(a) Early metaphase

(b) Late metaphase

(c) Early anaphase (d) Early telophase

6. The number of chromatids in a chromosome at anaphase is [CBSE PMT 1992; BHU 1994; AFMC 1995]

(a) 2 in mitosis and 1 in meiosis

(b) 1 in mitosis and 2 in meiosis

(c) 2 each in mitosis and meiosis

(d) 2 in mitosis and 4 in meiosis

7. The major event that occurs during the anaphase of mitosis, which brings about the equal distribution of chromosomes, is [KCET 2006]

(a) Replication of the genetic material

(b) Splitting of the chromatids

(c) Splitting of the centromeres

(d) Condensation of the chromatin

In the somatic cell cycle [CBSE PMT 2004]

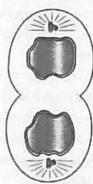

(a) A short interphase is followed by a long mitotic phase

(b) G₂ phase follows mitotic phase

(c) In G₁ phase DNA content is double the amount of DNA present in the original cell

(d) DNA replication takes place in S-phase

A stage in cell division is shown in the figure. Select the answer which gives correct identification of the stage with its characteristics

INEET 20131

(a)	Telophase	Endoplasmic reticulum and nucleolus not reformed yet
(b)	Telophase	Nuclear envelop reforms, Golgi complex reforms
(c)	Late anaphase	Chromosomes move away from equatorial plate, Golgi complex not present
(d)	Cytokinesis	Cell plate formed, mitochondria distributed between two daughter cells

Meiosis takes place in 10.

[NEET 2013]

- (a) Megaspore
- (b) Meiocyte
- (c) Conidia
- (d) Gemmule
- The complex formed by a pair of synapsed homologous 11. chromosomes is called
 - [NEET 2013]

- (a) Axoneme
- (b) Equatorial plate
- (c) Kinetochore
- (d) Bivalent
- 12. DNA replication in bacteria occurs
- [NEET 2017]
- (a) During S phase
- (b) Within nucleolus
- (c) Prior to fission
- (d) Just before transcription

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- If both the assertion and the reason are true and the reason (a) is a correct explanation of the assertion
- If both the assertion and reason are true but the reason is (b) not a correct explanation of the assertion
- If the assertion is true but the reason is false (c)
- If both the assertion and reason are false (d)
- If the assertion is false but reason is true (e)
- Synthesis of DNA takes place in the S-1. Assertion phase of interphase.
 - Every chromosome, during metaphase, has Reason
 - two chromatids. [KCET 2010]
- Reduction division occurs in anaphase-I. 2. Assertion So there is no need of meiosis.
 - Reason Meiosis-II occurs to separate homologous
 - [AIIMS 2009] chromosomes.
- 3. Assertion Karyokinesis occurs in M-phase.
 - Cell division stops in M-phase. Reason
- Interphase is resting stage. 4. Assertion
 - Reason The interphase cell is metabolically inactive.
- DNA synthesis occurs in G₁ and G₂ periods 5. Assertion of cell cycle.
 - During G1 and G2 phase the DNA contents Reason
- 6. Assertion Mitosis maintains the genetic similarity of

become double.

- somatic cells.
 - Chromosomes do not undergo crossing Reason
- 7. Chiasmata is formed during diplotene. Assertion
 - Chiasmata are formed due to deposition of Reason nucleoproteins.

- chromosomes show 8. Assertion During zygotene, bivalent stage.
 - Bivalent is half the number of chromosomes. Reason
- Meiosis takes place in pollen mother cells. Assertion
- Each pollen mother cell produce 4 haploid Reason [AIIMS 1996]
- pollen grains. Meiotic division results in the production of Assertion 10.
 - haploid cells.
 - occurs during zygotene of Reason Synapsis [AIIMS 1998] meiosis.

Answers and Solutions

Cell division

- (a) Condensation of chromosomes occurs in the prophase-I. After that chromosome moves toward the poles.
- (b) The most important role of meiosis is to maintain haploid phase.
- (a) Colchicine is obtained from colchicum autumnale plant, which inhibits the formation of spindle fibers in metaphase.
- 10. (d) When cells are not to divide after G_1 phase and start undergoing differentiation into specific types of cells such cells are said to be in G_0 phase/ G_0 state.
- 14. (d) Cyclin is a protein, which participates in cell division.
- (d) Diakinesis is the stage of meiosis. For the study of meiosis young flower bud is the best material.
- (d) Leptotene, zygotene, pachytene, diplotene and diakinesis all are successive stages of meiosis.
- (a) Synaptonemal complex is formed during meiotic prophase first.
- (a) Synaptonemal complex is formed in meiotic prophase-I, which was first observed by Moses in 1956.
- (b) Knot like structure 'Chromomeres' found in the stage leptotene of prophase first of meiosis.
- 20. (b) During meiosis, daughter cells has the half number of chromosomes with respect to parent cells. Therefore daughter cell will be genetically different.
- 22. (d) In meiosis, crossing over takes place in pachytene, after that chromosome get repulsion in diplotene.
- (c) During cleavage, cell divides mitotically without taking any gap, so that is known as closed mitosis.

- 27. (d) During the pachytene, chromosomes get crossed with each other and forms a four stranded or tetrad appearance.
- 29. (b) The crossing over of homologous chromosome occurs in Pachytene of prophase first of meiosis. It is known as recombination.
- 34. (b) Gamete is haploid while somatic cell is diploid. After S-phase it will contain twice the number of chromosomes and four times the amount of DNA.
- **35.** (a) In prophase I of meiosis I, the correct sequence of events are
 - B synapsis in Zygotene
 - C -crossing over in pachytene in diakinesis
 - D disappearance of nucleolus in diakinesis
- 38. (b) Because in metaphase, chromosomes are present in bivalent form on equator. Chromosomes are much condense and well visible.
- 39. (c) S or synthesis phase marks the period where DNA synthesis takes place. During this time the amount of DNA per cell doubles.
- 41. (d) In meiosis II division is equational division; thus centromere divides and chromatid move towards the pole during anaphase-II.
- 44. (b) One chromosome forms one chromosome group in metaphase-I after splitting of tetravalent condition.
- **46.** (a) In M=phase, both 4C and 2C of DNA are present in different stages.
- **49.** (c) The sequence of interphase (I-Phase) is $G_1 \to S \to G_2$.
- 55. (a) Diagrame first represents crossing over that takes place in pachytene stage of prophase I during meiosis.
- 56. (c) Because they are thread like structures, which contract to pull the chromosome towards pole.
- **57.** (d) Because interphase is the growth phase of cell. Centrioles replicate in G_2 of interphase of cell cycle but some authors reported this duplication in early prophase.
- **66.** (c) Crossing over is an enzyme-mediated process and the enzyme involved is called recombinase.
- 73. (d) All the above; four nuclei formed are not similar to parent ones because they are haploid in nature. Homologous chromosome pairs are exchange parts because in crossing over exchange of chromatid arms takes place and number of chromosomes gets halved.
- **76.** (b) In zygotene of prophase of meiosis, chromosomes pairing occurs for crossing over.
- **83.** (a) Because one cell produces 4 daughter cells after meiotic division, thus 50 cells produce $50 \times 4 = 200$ daughter cells.
- **85.** (a) III-Prophase, IV-Metaphase, I-Anaphase (I), II-Telophase (I), V-Telophase (III)
- 87. (d) The number of different haploid cells arise by meiosis can be calculated by 2ⁿ
 n = number of haploid chromosome.

- 88. (a) Leptotene is a stage in the prophase I of meiosis. In this stage chromosome appears thin and long.
- (a) Calcium Dependent Kinases (CDKs) have the ability to control cell cycle activities during cell division.
- 94. (d) Synapsis is the pairing of homologous chromosomes during zygotene stage of prophase I of meiotic division-I. The homologous chromosomes come from the mother and father.
- **102.** (c) For wheat, 2n = 6x = 42.

 $\therefore x = 7$

'x' represents basic or genomic number.

- 103. (c) Centrioles are organelles important in spindle formation during nuclear division. These are found commonly in most animal cells and some lower plant cells.
- 104. (a) A single mitotic division results in the production of two cells from a single one.
- 108. (a) For the formation of 100 grains of wheat 100 pollen grains and 100 megaspores are required. Each microspore mother cell produces 4 microspores (pollen grains) as a result of reduction division. Hence for the formation of 100 pollen grains, $\frac{100}{4} = 25 \, PMC$ are needed and each will undergo one reduction division. Each megaspore mother cell will produce 4 megaspores in which one become functional and other three degenerate. Thus each MMC produces one megaspore. So 100 MMC are required to produce 100 megaspores. Total number of reduction divisions to produce 100 grains is 100 + 25 = 125.
- 112. (d) Mitotic cells division is equational division where a mother cell divides to form 2 daughter cells. So to produce 256 cells from a single cell, 8 mitotic divisions will occur which can be represented as $1 \rightarrow 2 \rightarrow 4 \rightarrow 8 \rightarrow 16 \rightarrow 32 \rightarrow 64 \rightarrow 128 \rightarrow 256$.
- **115.** (c) Because first phase of meiosis includes reduction division while second phase exhibits mitotic divisions.
- 116. (c) As a result of it pollen grains formed.
- **120.** (c) The check points are basically present in the interphase.
- **126.** (a) Pairing between the homologous chromosomes takes place in zygotene stage of prophase-I.
- **129.** (c) Because each chromosome bears two chromatids and at the end of meiosis–I chromosome number becomes halved i.e., 4 and number of chromatids are $4 \times 2 = 8$.
- 134. (d) $G_1 \rightarrow 6$ pairs or 12 chromosomes or 12 chromatids or 12 DNA molecules. After S or $G_2 \rightarrow 6$ pairs or 12 chromosomes or 24 chromatids or 24 DNA molecules.
- 135. (d) As a result of meiosis only haploid cells are produced.
- 136. (d) Spindle depolymerization is caused by Colchicine.
- 138. (b) DNA replication occurs in S-phase of cell cycle.

Critical Thinking

- (b) The duplication of DNA takes place in 'S' stage of interphase after that cell reaches in G₂ phase. That is why the strand of DNA in G₂ phase will be two.
- (c) In absence of colchicines mitotic division will be continued in normal way.
- (d) In the somatic cell cycle S-phase is a stage of replication of each chromosome by synthesis of a new DNA molecule on the template of existing DNA.

Assertion and Reason

1. (a)

- (b) Anaphase-I involves separation of homologous chromosomes into different daughter cells. So, meiosis I is a reductional division. But each chromosome is still formed of two sister chromatids joined at the common centromers. Anaphase-I results in reduction in number of chromosomes but each chromosome has double amount of DNA, so, meiosis-II occurs, during, which chromatids of each chromosome separate into different cells. Main aim of meiosis II is to separate genetically modified chromatids of each homologous chromosome formed during crossing over in meiosis-I
- (d) M-phase represents the phase of actual division. It consists of karyokinesis (The division of nucleus) followed by cytokinesis (The division of cytoplasm). Cell divisions stop after M-phase.
- 4. (c) Previously interphase is called resting stage because there is no apparent activity related to cell division. The interphase cell is metabolically quite active. Interphase consist of three subphases (G₁, G₂ and S). Synthesis of DNA occurs in S phase. G₁ is the period between the end of mitosis and the start of S phase. G₂ is the interval between S phase and start of mitosis. As the synthesis of DNA occurs in S phase so it is considered as metabolically active phase.
- (d) The synthesis of DNA occurs only in a restricted portion of the interphase during S period, which is preceded and followed by two "gap" periods of interphase (G₁ and G₂) in which there is no DNA synthesis. G₁ is the period between the end of mitosis and the start of DNA synthesis. S is the period of DNA synthesis and G₂, the interval between the end of DNA synthesis and the start of mitosis. During G₂ a cell contains two times (4C) the amount of DNA present in the original diploid cell (2C). Following mitosis the daughter cell again enter the G₁ period and have a DNA content equivalent to 2C.
- 6. (a) Mitosis keeps all the somatic cells of an organism genetically similar, resembling the fertilized egg. Mitosis involves replication and equitable distribution of all the chromosomes so that all the cells of a multicellular organism have the same number and type of chromosomes. This helps in proper co-ordination among different cells.
- 7. (c) The points of attachment between the homologous chromosomes after the partial dissolution of nucleoprotein complex are called chiasmata. It occurs during diplotene substage of prophase I.
- 8. (b) During zygotene, because of the pairing of the homologous, the nucleus contains half the number of chromosomes. Each unit is a bivalent composed of two homologous chromosomes.
- (a) Meiosis occurs in pollen mother cells. All pollen mother cells are diploid and produce haploid pollen grains after meiosis.
- 10. (a) Diploid cell produce haploid cell by meiosis. It occurs due to synapsis. A chromosome has two chromatids, hence a bivalent has 4 chromatids.

ET Self Evaluation Test

Bivalents in meiosis are

[RPMT 2001]

- (a) Tetrad
- (b) Pairs of non-homologous chromosomes
- (c) Pairs of several chromatids
- (d) Pairs of homozygous chromosomes
- 2. Which type of cell division occurs in the gonads [RPMT 2001]
 - (a) Mitosis only
- (b) Meiosis
- (c) Both (a) and (b)
- (d) Amitosis and meiosis
- 3. The spindle fibre contracts in

[KCET 1998]

- (a) Metaphase I
- (b) Anaphase II
- (c) Prophase II
- (d) Telophase II
- 4. If there were 4 chromosomes present during prophase, how many chromosomes are there in each cell at the end of anaphase II [Pune CET 1998]
 - (a) 16

(b) 4

(c) 2

- (d) 8
- Which is not characteristic of meiosis

[AIIMS 2011]

- (a) Two stages of DNA replication, first before meiosis I and second before meiosis II
- (b) Recombination and crossing over
- (c) Sister chromatids separate during anaphase II
- (d) Nuclear membrane disappears towards end of prophase
- Cell division in blue-green algae is more or less similar to that in [MP PMT 1994]
 - (a) Red algae
- (b) Green algae
- (c) Brown algae
- (d) Bacteria

- 7. Which out of the following is not a divisional stage
 - (a) Telophase
- (b) Interphase
- (c) Metaphase
- (d) Prophase
- 8. Crossing over is advantageous because it brings about
 - (a) Variation
- (b) Linkage
- (c) Inbreeding
- (d) Stability
- Cellular structure always disappears during mitosis is
 - (a) Cell wall
- (b) Cell membrane
- (c) Nucleolus
- (d) All the above
- Anastral mitosis is found in

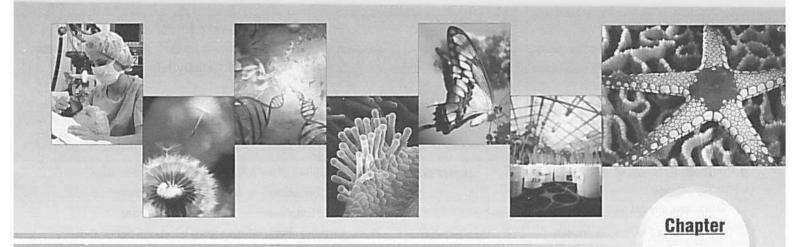

[MHCET 2001]

- (a) Animals
- (b) Higher plants
- (c) Bacteria
- (d) Cyanobacteria

S Answers and Solutions

1	a	2	C	3	b	4	С	5	a
6	d	7	b	8	a	9	C	10	b

- (a) Bivalent formation occurs in pachytene of meiosis, In this stage, two chromatids of homologous chromosome (Bivalent) later on forms a cross and now showing a tetravalent or tetrad stage.
- (c) Mitosis and meiosis both type of cell division occurs in gonads. Mitosis during growth and development and meiosis during gametogenesis.

4.1

Plant physiology (Physis = nature of life; logos = study) is the branch of botany which deals with the study of life activities of plants. It includes the functional aspects of life processes both at cellular as well as sub-cellular level.

Concept of water relation

Water is mainly absorbed by the roots of the plants from the soil, then it moves upward to different parts and is lost from the aerial parts, especially through the leaves. Before taking up the absorption and movement of water in plants, it is worthwhile to understand the phenomenon of imbibition, diffusion and osmosis involved in the water uptake and its movement in the plants.

Imbibition (L. imbibere – to drink): The process of adsorption of water by hydrophilic surfaces of a substance without forming a solution is called 'imbibition'. It is a type of diffusion by which movement of water takes place along a diffusion gradient. The solid particles which adsorb water or any other liquid are called imbibants. The liquid which is imbibed is known as imbibate.

Characteristics of imbibition : The phenomenon of imbibition has three important characteristics :

- (i) **Volume change**: During the process of imbibition, imbibants increase in volume. It has been observed that there is an actual compression of water. This is due to arrangement of water molecules on surface of imbibant and occupy less volume than the same molecules do when are in free stage in the normal liquid. e.g., If a dry piece of wood is placed in water, they swell and increases in its volume.
- (ii) **Production of heat :** As the water molecules are adsorbed on the surface of the imbibant, their kinetic energy is released in the form of heat which increases the temperature of the medium. It is called heat of wetting (or heat of hydration). *e. g.*, during kneading, the flour of wheat gives a warm feeling due to imbibition of water and consequent release of heat.

(iii) **Development of imbibitional pressure :** Imbibition pressure can be defined as the maximum pressure that an imbibant will develop when it is completely soaked in pure water. Imbibition pressure is also called as the matric potential because it exists due to the presence of hydrophilic substances in the cell which include organic colloids and cell wall.

Factors influencing the rate of imbibition

Nature of imbibant : Proteins are the strongest imbibants of water, starch less strong, cellulose being the weakest.

Surface area of imbibant: If more surface area of the imbibant is exposed and is in contact with liquid, the imbibition will be more.

Temperature : Increase in temperature causes an increase in the rate of imbibition.

Degree of dryness of imbibant: If the imbibant is dry it will imbibe more water than a relatively wet imbibant.

Concentration of solutes : Increase in the concentration of solutes in the medium decreases imbibition.

pH of imbibant: Proteins, being amphoteric in nature, imbibe least in neutral medium. Towards highly acidic or highly alkaline pH, the imbibition increases till a maximum is reached, there after it starts slowing down.

Significance of imbibition

- (1) The water is first imbibed by walls of root hairs and then absorbed.
- (2) Water is absorbed by germinating seeds through the process of imbibition and helps in rupturing of seed coat (made up of cellulose).
- (3) The water moves into ovules which are ripening into seeds by the process of imbibition.

UNIVERSAL BOOK DEPOT 1960

Diffusion : The movement of the molecules of gases, liquids and solids from the region of higher concentration to the region of lower concentration is known as diffusion.

It may occur between gas and gas (e.g., diffusion of ammonia into air), liquid and liquid (e.g., diffusion of alcohol into water), or solid and liquid (e.g., diffusion of sugar into water).

Diffusion pressure: It is a hypothetical term coined by Meyer (1938) to denote the potential ability of the molecules or ions of any substance to diffuse from an area of their higher concentration to that of their lower concentration.

Diffusion pressure deficit (DPD) or Suction pressure (SP): The term diffusion pressure (DP) and diffusion pressure deficit (DPD) were putforth by B.S. Meyer in 1938. Now a days, the term water potential (ψ) is used which is equal to DPD, but negative in value. The term suction pressure was putforth by Renner (1915).

The amount by which the diffusion pressure of water or solvent in a solution is lower than that of pure water or solvent is known as diffusion pressure deficit (DPD)'. Diffusion pressure deficit is the water absorbing capacity of a solution. Therefore, DPD can also be called **suction pressure (SP)**.

Factors influencing rate of diffusion

Temperature : Increase in temperature leads to increase in the rate of diffusion.

Pressure : The rate of diffusion of gases is directly proportional to the pressure. So the rate of diffusion increases with increase in pressure. Rate of diffusion ∞ pressure.

Size and mass of diffusing substance: Diffusion of solid is inversely proportional to the size and mass of molecules and ions.

Rate of diffusion
$$\approx \frac{1}{\text{Size} \times \text{Mass of particles}}$$

Density of diffusing substance: The rate of diffusion is inversely proportional to the square root of density of the diffusing substance. Larger the molecules, slower will be the rate of diffusion. This is also called Graham's law of diffusion.

$$D \propto \frac{1}{\sqrt{d}}$$
 (D = Diffusion and d = Density of diffusing substance).

According to the density the diffusion of substances takes place in following manner:

The vapours of volatile liquids (scent or petrol) and solids (camphor) also diffuse like gases.

Density of the medium: The rate of diffusion is slower, if the medium is concentrated. Thus, a gas would diffuse more rapidly in vacuum than in air. Substances in solution also diffuse but at a much slower rate than gases.

Diffusion pressure gradient (DPG): The rate of diffusion is directly proportional to the difference of diffusion pressure at the two ends of a system and inversely proportional to the distance between the two.

Significance of diffusion

- Gaseous exchange during the processes of photosynthesis and respiration takes place with the help of diffusion.
- (2) The process of diffusion is involved in the transpiration of water vapours.
- (3) Aroma of flowers is due to diffusion of volatile aromatic compounds to attract pollinating animals.
- (4) During passive salt uptake, the ions are absorbed by process of diffusion.
 - (5) Diffusion helps in translocation of food materials.
- (6) Gaseous exchange in submerged hydrophytes takes place by general surface of the cells through diffusion.

Permeability: Permeability is the degree of diffusion of gases, liquids and dissolved substances through a membrane. Different types of membranes may be differentially permeable to different substances.

Types of membranes: On the basis of permeability.

Permeable membrane : These membranes allow free passage of solvent (water) and most of the dissolved substances. *e.g.*, cell wall in plant cells. Filter paper is made up of pure cellulose it also functions as permeable membrane.

Impermeable membrane: This type of membranes with deposits of waxy substances like cutin and suberin, do not allow the entry of water, dissolved substances and gases. e.g., suberized walls of cork cells, cuticle layer of leaf.

Semi-permeable membrane: These membranes permit the movement of solvent molecules only through them, but prevent the movement of solute particles. e.g., egg membrane, animal bladder, parchment paper, copper ferrocyanide membrane, membranes of collodion.

Selectively or Differentially permeable membrane: This type of membranes allow selective passage of solutes along with solvent, through them.

Many biological membranes such as cell membrane (plasmalemma), tonoplast (vacuolar membrane) and the membranes surrounding the sub-cellular organelles are selectively permeable. A non-living selectively permeable membrane is cellophane.

Osmosis: Osmosis (Gr. Osmos = a pushing or impulse) was discovered by Abbe Nollet in 1748 and also coined the term 'osmosis'. First of all Traube (1867) used copper ferrocyanide and developed semipermeable membrane to show its utility in the osmosis of plant physiology. First time Pfeffer in (1887) developed osmoscope by using semipermeable membrane.

Osmosis is special type of diffusion of a liquid, when solvent moves through a semipermeable membrane from a place of higher diffusion pressure to a place of lower diffusion pressure.

Or

It is the migration of solvent from a hypotonic solution (of lower concentration) to hypertonic solution (of higher concentration) through a semi-permeable membrane to keep the concentration equal.

In formalin preserved *spirogyra* filament, selective permeability of plasma membrane is lost and hence no effect on placing in hypertonic solution.

Reverse Osmosis: It is the reverse movement of water through a semipermeable membrane from a more concentrated solution to a more dilute solution by applying external pressure on the more concentrated solution.

It is used in removing salts from saline water as well as extra – purification of water.

Osmotic pressure (OP): Pfeffer coined the term osmotic pressure.

Osmotic pressure is that equivalent of maximum hydrostatic pressure which is produced in the solution, when this solution is separated from its pure solvent by a semipermeable membrane. Osmotic pressure of a solution is greater than pure solvent.

Types of osmosis: Depending upon the movement of water into or outside of the cell, osmosis is of two types.

Endosmosis: The osmotic flow of water into a cell, when it is placed in a solution, whose solute concentration is less than that of the cell sap, is called endosmosis *e.g.*, swelling of raisins, when they are placed in water.

When a fish of marine water kept in fresh water then it will die due to endosmosis.

An animal cell placed in pure water will swell up and bursts.

Pollen grains of some of plants germinate on stigma soon but they burst in water or dilute sugar solution.

Exosmosis: The osmotic outflow of water from a cell, when it is placed in a solution, whose solute concentration is more than that of the cell sap, is called exosmosis. *e.g.*, shrinkage of grapes, when they are placed in strong sugar solution.

Osmotic concentrations (Types of solutions)

Hypotonic solution (hypo = less than). A solution, whose osmotic concentration (solute potential) is less than that of another solution or cell sap is called hypotonic solution. If a cell is placed in such a solution, water starts moving into the cell by the process of endosmosis, and cell becomes turgid.

Hypertonic solution (hyper = more than). A solution, whose osmotic concentration (solute potential) is more than that of another solution or cell sap is called hypertonic solution. If a cell is placed in such a solution, water comes out of the cell by the process of exosmosis and cell becomes flaccid. If potato tuber is placed in concentrated salt solution it would becomes shrink due to loss of water from its cell.

Isotonic solution (iso = the same). A solution, whose osmotic concentration (solute potential) is equal to that of another solution or cell sap, is called isotonic solution. If a cell is placed in isotonic solution, there is no net changes of water between the cell and the solution and the shape of cell remain unchanged.

In xerophytes, the osmotic concentration of cell sap is more than the normal. The osmotic pressure of given solution can be calculated by following formula.

Osmotic pressure = CST

Where, C = Molar concentration of solution, S = Solution constant, which is 0.082 and T = Absolute temperature i.e., $273^{\circ}K$.

Significance of osmosis in plants

- (1) The phenomenon of osmosis is important in the absorption of water by plants.
- (2) Cell to cell movement of water occurs throughout the plant body due to osmosis.
- (3) The rigidity of plant organs (i.e., shape and form of organism) is maintained through osmosis.
 - (4) Leaves become turgid and expand due to their OP.
- (5) Growing points of root remain turgid because of osmosis and are thus, able to penetrate the soil particles.
 - (6) Opening and closing of stomata is affected by osmosis.
- (7) Movement of plants and plant parts, e.g., movement of leaflet of Indian telegraph plant.

Turgor pressure (TP): The plant cell, when placed in pure water, swells but does not burst. Because of negative osmotic potential of the vacuolar solution (cell sap), water will move into the cell and will cause the plasmalemma be pressed against the cell wall. The actual pressure that develops that is the pressure responsible for pushing the membrane against cell wall is termed turgor pressure.

Significance of turgidity in plants

- (1) It provides stability to a cell.
- (2) Turgidity keeps the cell and their organelles (mitochondria, plastids and microbodies) fully distended. This is essential for plants to live and grow normally.
- (3) Turgor pressure helps in cell enlargement, consequently in stretching of the stems and in keeping leaves erect and fully expanded.
- (4) The turgid cells provide mechanical support necessary for the non woody tissues (maize, sugarcane, banana etc.).
- (5) Loss of turgidity leads to wilting of leaves and drooping of shoots.
- (6) The opening and closing of stomata are regulated by the turgidity of the guard cells.
- (7) Leaf movements (seismonastic movement) of many plants (such as bean, sensitive plant Mimosa pudica) are controlled by loss and gain of cell turgor.
- (8) Due to turgor pressure plumule and radicles force out from seeds at the time of seed germination.

Wall pressure (WP): Wall pressure (WP) may, therefore, be defined as 'the pressure exerted by the cell wall over the protoplast to counter the turgor pressure. Normally wall pressure is equal and opposite to turgor pressure (WP =TP) except when the cell become flaccid. The value of the two forces continue to rise with the continued entry of water, till the cell becomes fully turgid.

UNIVERSAL BOOK DEPOT 1950

Interrelationship of DPD (S.P.), OP and TP (WP): DPD indicates the sucking power of suction pressure. As water enters into the cell the TP of the cell is increased. Cell wall exerts equal and opposite WP against TP. The actual force responsible for entry of water will be therefore OP-TP

i.e.,
$$DPD = OP - WP$$
 (As $WP = TP$)
 $DPD = OP - TP$

Consider that a plant cell with OP = 10 atm. is immersed in pure water. In the beginning TP inside the cell is zero i.e.,

$$DPD = OP = 10 atm.$$

When water enters into the cell, TP increases. Turgidity increases and cell wall develops equal and opposite WP. At the stage of equilibrium TP = 10 atm. and DPD will become zero. It is important to note that OP was same when cell was flaccid and turgid.

DPD = OP - TP
=
$$10 - 0 = 10$$
 (when flaccid)
= $10 - 10 = 0$ (when turgid)

The entry of water in cell to cell depends upon the DPD and not on OP and TP. This can be examplified as follows:

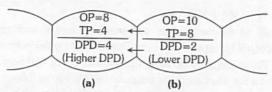

Fig: 4.1-1 Relation between diffusion pressure deficit and entrance of water in the cell

Since the DPD of cell A is more, it has less water and, therefore water would diffuse from cell B into the cell A (because that DPD of cell B is less than that of A or it has more water than cell A has). The entry of water into the cell A would stop when DPD of both the cells become equal. In this way water moves from a cell with less DPD into the cell with more DPD. Thus, DPD is the osmotic parameter, which determines the flow of water from one cell to another.

Under given suitable conditions, the DPD is more than OP when TP is negative.

DPD is maximum in a flaccid cell.

Plasmolysis (Gr. Plasma = something formed; lysis = loosing): "The shrinkage of the protoplast of a living cell from its cell wall due to exosmosis under the influence of a hypertonic solution is called plasmolysis". The stage of plasmolysis, when the protoplast just begins to contract away from the cell wall is called incipient plasmolysis. The stage when the cell wall has reached its limit of contraction and the protoplast has detached from cell wall attaining spherical shape is called evident plasmolysis. If a cell with incipient plasmolysis is placed in a hypertonic solution it will show more plasmolysis.

Deplasmolysis: "The swelling up of a plasmolysed protoplast due to endosmosis under the influence of a hypotonic solution or water is called deplasmolysis'. Deplasmolysis is possible only immediately after plasmolysis otherwise the cell protoplast becomes permanently damaged. The value of TP becomes zero at the time of limiting plasmolysis and below zero during incipient and evident plasmolysis. Leaf of *Tradescantia* is used for demonstration of plasmolysis in laboratory.

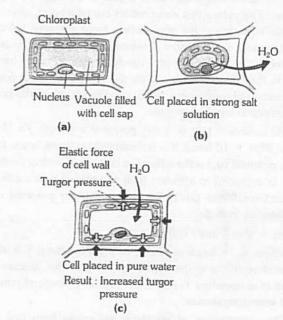

Fig: 4.1-2 Plasmolysis and deplasmolysis

(a) Normal cell (b) Plasmolysed cell

(c) Deplasmolysed cell and increased turgor pressure

Significance of plasmolysis

- (1) The OP of a cell can be measured by plasmolysis. The OP of a cell is roughly equal to the OP of a solution that causes incipient plasmolysis in the cell.
- (2) Salting of pickles, meat, fishes etc. and addition of sugar to jams, jellies, cut fruits etc., prevent their decay by microbes, as the latter get killed due to plasmolysis or due to high concentration of salt or sugar.
- (3) By salting, the weeds can be killed from tennis courts and the growth of plants can be prevented in the cracks of walls.
- (4) Plasmolysis is helpful in determining whether a particular cell is living or dead as plasmolysis does not occur in a dead or non living cell.

Water potential (ψ): The term water potential was coined by slatyer and Taylor (1960). It is a modern term which is used in placed of D.P.D. The movement of water in plants cannot be accurately explained in terms of difference in concentration or in any other linear expression. The best way to express spontaneous movement of water from one region to another is in terms of the difference of free energy of water between two regions. Free energy is the thermodynamic parameter, that determine the

direction in which physical and chemical changes must occur. The potential energy of water is called water potential. *e.g.*, water is stored behind a dam. When the water runs downhill, its potential energy can be converted to electrical energy. This conversion of energy of water is due to gravity. The other source that provides energy to water is pressure. The increasing pressure increases the free energy there by increasing water potential.

Water running downhill due to gravity can be made to run uphill by overcoming the water potential (energy) by applying pressure. This means that water moves from the point, where water potential is greater to the other, where water potential is less. The difference in water potential between two points is a measure of the amount of work or energy needed to move water from one point to the other. Thus, based on the concept of water potential, the direction of water movement can be predicted. Water potential is measured in terms of pressure.

Measurement unit of water potential is pascal, Pa (1 mega pascal, Mpa = 10 bars). It is represented by Greek letter, Psi $(\psi).$ Water potential (ψ_w) is the difference between chemical potential of water at any point in a system $(\mu\omega)$ and that of pure water under standard conditions $(\mu\omega^\circ).$ The value of water potential can be calculated by formula :

$$\psi_w = (\mu \omega) - (\mu \omega^\circ) = RT \ 1 \ n \ e/e^\circ$$

where ψ_w = water potential, R is gas constant, T is absolute temperature (K), e is the vapour pressure of the solution in the system at temperature T, and e° the vapour pressure of pure water at the same temperature.

The direction in which water will move from one cell to another cell depends on water potential in two regions. Water potential is measured in bars. A bar is a pressure unit which equals 14.5 lb/in^2 , 750 mm Hg or 0.987 atm.

Water potential of pure water at normal temperature and pressure is zero. This value is considered to be the highest. The presence of solute particles reduces the free energy of water and thus decreases the water potential. Therefore, water potential of a solution is always less than zero or has negative value.

Component of water potential: The water potential (ψ) in a plant cell or tissue can be written as the sum of the matric potential (ψm) due to binding of water to cell walls and cytoplasm, the solute potential (ψs) due to concentration of dissolved solutes, which by its effect on the entropy components reduces the water potential and the pressure potential (ψp) due to hydrostatic pressure, which by its effect on the energy components increases the water potential:

$$\psi = \psi m + \psi s + \psi p$$
(1)

Matric potential (ψ m): Matric is the term used for the surface (such as, soil particles, cell walls, protoplasms, etc.) to which water molecules are adsorbed. The matric potential (ψ m) is the component of water potential influenced by the presence of a matrix. It has got a negative value. In case of plant cells and tissues, the matric potential is often disregarded because it is not significant in osmosis. Thus, the above equation (1) may be simplified as follows:

$$\psi = \psi s + \psi p \qquad \dots (2)$$

In normal cells of mesophytes and hydrophytes it is almost negligible.

Solute potential (ψ s): Solute potential is also known as *Osmotic potential*. It is defined as the amount by which the water potential is reduced as a result of the presence of solute. Solute potentials or osmotic potentials (ψ s) are always in negative values (number). The term solute potential takes the place of osmotic pressure (π ; Pi) expressed in bars with a negative sign.

$$\psi_{\circ} = -\pi$$

Pressure potential (ψ p): Plant cell wall is elastic and it exerts a pressure on the cellular contents. As a result of inward wall pressure, hydrostatic pressure is developed in the vacuole termed as turgor pressure. The pressure potential is usually positive and operates in plant cells as wall pressure and turgor pressure.

Its magnitude varies between +5 bars (during day) and +15 bars (during night).

Physical states of cell: Three physical states of cell, according to their water potential, are as follows:

In case of fully turgid cell: In case of fully turgid cell, the net movement of water into the cell is stopped. The cell is in equilibrium with the water outside. The water potential in such a case will be zero (0).

Water potential = Osmotic potential + Pressure potential

$$\psi = \psi s + \psi p$$

A cell at full turgor has its osmotic potential and pressure potential equal but opposite in sign. Therefore, its water potential will be zero. For example, supposing a cell has its ψ s of -10 bars and ψ p of 10 bars the resultant water potential will be zero as follows:

$$\psi = \psi \, s + \psi \, p$$
$$\psi = -10 \, bars + 10 \, bars$$
$$\psi = 0 \, bars$$

In case of flaccid cell: When a plant cell is flaccid, its turgor becomes zero (corresponding to a turgor pressure of a 0 bars). Zero turgor is approached under natural conditions when a tissue is severely wilted. A cell at zero turgor has an osmotic potential (ψ s) equal to its water potential (ψ). For example, supposing a flaccid cell has an osmotic potential of -10 bars and pressure potential (ψ p) of 0 bars.

Water potential = Osmotic potential + Pressure potential

$$\psi = \psi s + \psi p$$

 $\psi = -10 \text{ bars} + 0 \text{ bars}$
 $\psi = -10 \text{ bars}$

The water potential of the cell will be -10 bars, which is less as compared to the water potential of pure water (0 bars).

In case of plasmolysed cell: When the vacuolated parenchymatous cells are placed in solutions of sufficient strength the protoplast decreases in volume to such an extent that they shrink away from the cell wall. The cells are plasmolysed. Such cells have negative value of pressure potential (negative turgor pressure). The resultant water potential will be more negative, as for example, a plasmolysed cell has osmotic potential of –10 bars and pressure potential of –2 bars the water potential of the cell will be –12 bars.

UNIVERSAL BOOK DEPOT 1960

Water potential = Osmotic potential + Pressure potential

 $\psi = \psi s + \psi p$ $\psi = -10 + (-2)$

 $\psi = -12$ bars

Movement of water between two adjacent cells: Suppose A and B are two adjacent plant cells where osmotic movement of water can occur. Cell A has osmotic potential (ψs) of -16 bars and pressure potential of 8 bars. The cell B has osmotic potential of -12 bars and pressure potential of 2 bars. The movement of water will be as follows:

Cell A	Cell B
$\psi s = -16$ $\psi p = 8$	$\psi s = -12$ $\psi p = 2$
$\psi = \psi s + \psi p$ $= -16 + 8 = -8.$	$\psi = \psi s + \psi p$ $= -12 + 2 = -10.$

Wilting: A plant usually fails to survive if it is conditioned to water deficiency. The symptoms appear in the plant, plant parts or in the cells due to scarcity of water are termed as wilting. It is loss of turgidity causing folding and drooping of leaves and other soft aerial parts of the plant. It is of three types:

- Incipient wilting: There is no external symptoms but the mesophyll cells lose a part of their water content during midday due to transpiration.
- (2) Temporary wilting: It occurs during midday and is visible externally due to drooping of leaves and young shoots. At noon the rate of transpiration is quite high as compared to water absorption, which decreases further due to depletion of water around rootlets. It is corrected in the afternoon when transpiration decreases.
- (3) **Permanent wilting:** It is the last stage in wilting when the aerial parts do not regain turgidity even if placed in water saturated atmosphere. It is caused by decrease in water content of the soil which increases TSMS (Total soil moisture stress) or resistance to absorption to such an extent that plant roots are unable to absorb water. Permanent Wilting Percentage (PWP) is the percentage of water on the dry weight basis of the soil that is present in the soil when the plants growing in it first touch the condition of permanent wilting. This value varies between 1–15% and depends upon the texture of the soil *e.g.*, clay has higher PWP than sand.

Absorption of water

Water is absorbed from soil by root system and specially by younger parts (i.e., root tips). In higher plants water is absorbed through root hairs.

Soil water: The chief source of soil water is rain. In soil water is found in different forms. The total amount of water present in the soil is called holard, of this the available to the plant is called chresard and the water which cannot be absorbed by the plants is called echard.

Water occurs freely deep in the soil and above the parent rock, it is called ground water. These are briefly described below: **Gravitational water:** When the water enters the soil and passes the spaces between the soil particles and reaches the water table, the type of soil water is called gravitational water.

Capillary water: It is the water which is held around soil particles in the capillary space present around them due to force like cohesion and surface tension. This is the water which can be utilised by the plants. It is also called growth water. It occurs in the form of films coating smaller soil particles.

The availability of capillary water to the plant depends upon its diffusion pressure deficit which is termed as the soil moisture stress. The plant cells have a DPD much more than the soil moisture stress for proper absorption of water.

Hygroscopic water : This is the form of water which is held by soil particles of soil surfaces. The water is held tightly around the soil particles due to cohesive and adhesive forces. Cohesive and adhesive forces greatly reduce the water protential $(\psi\omega)$ and thus this type of water in soil is not available to plants.

Run-away water: After the rain, water does not enter the soil at all, but drained of along the slopes. It is called run-away water. Plants fail to avail this water.

Chemically combined water: Some of the water molecules are chemically combined with soil minerals (e.g., silicon, iron, aluminium, etc.). This water is not available to the plants.

Water vapour : That portion of the pore space in a soil which is not occupied by liquid water contain a soil atmosphere that always includes water vapour.

Water holding capacity: The amount of water actually retained by the soil is called field capacity or water holding capacity of the soil. It is about 25–35% in common loam soil. The excess amount of water beyond the field capacity produces water logging.

Soil atmosphere: In moderately coarse soils as well as in heavy soils (fine textured soil) that are with aggregated particles; there exists large interstitial spaces which facilitate the diffusion of gases. As a result the CO_2 produced in a soil by respiration of soil organisms and roots is able to escape rather easily and oxygen used up in this process diffuses into the soil with corresponding case.

Water absorbing organs: Plants absorb water mostly from the soil by their roots, but in some plants even aerial parts like stem and leaves also do the absorption of atmospheric water or moisture. Some important examples of such plants are Vitis, Solanum, Lycopersicon, Phaseolus, Kochia baosia and Beta.

However, maximum absorption of water is done by the roots.

This area is usually characterized by the presence of root hairs which serve to increase the area of contact between the root surface and soil.

The root hairs develop mainly at the tip just above the zone of elongation (cell maturation). A root hair is the unicellular tubular prolongation of the outer wall of the epiblema.

During water absorption the plasma membrane of root hair, the cytoplasm and the vacuole membrane (tonoplast) behave together as a single differentially permeable membrane. Root hairs are at the most 1.25 cm in length and never more than 10 mm in diameter.

The root-hairs of plants increase the absorption surface of a root system about 5 to 20 times and because they extend so widely through the soil they make available a supply of water that the plant could not otherwise obtain. Water potential of root hair cells is generally -1 to -4 atm.

Pathway of water movement in root: Water in the root moves through three pathways. Munch coined the term apoplast and symplast.

Apoplast pathway : The apoplastic movement of water occurs exclusively through the cell wall without crossing any membrane.

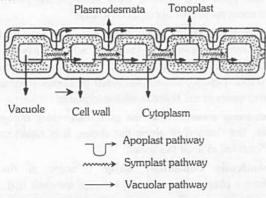

Fig: 4.1-3 Three pathways of water movement

Symplast pathway: The symplastic movement of water occurs from cell to cell through the plasmodesmata.

Transmembrane pathway: Water after passing through cortex is blocked by casparian strips present on endodermis. The casparian strips are formed due to deposition of wax like substance, suberin. In this pathway, water crosses atleast two membranes from each cell in its path. These two plasma membranes are found on entering and exiting of water. Here, water may also enter through tonoplast surrounding the vacuole i.e., also called as vacuolar pathway.

Mechanism of water absorption : Two distinct mechanisms which are independently operated in the absorption of water in plants. These mechanisms are :

(1) Active absorption (2) Passive absorption

Renner (1912, 1915) coined the term active and passive water absorption.

(1) Active absorption: Active absorption takes place by the activity of root itself, particularly root hairs. The factor responsible for water absorption is present within the roots. It utilizes metabolic energy. There are two theories of active absorption:

Osmotic theory: It was proposed by Atkins (1916) and Priestley (1922). It is purely a physical process, which does not directly require expenditure of energy.

A root hair cell functions as an osmotic system. Water is absorbed by the root hair due to osmotic differences between soil water and cells sap. The osmotic pressure of soil water remains below 1 atm, but that of cell sap is usually 2–8 atms. Thus, there exists a great difference in the osmotic pressures of the two sides or in other words there exists, water potential gradient between the soil solution and cell sap. The soil solution having less OP, has higher water potential than the cell sap with more OP (i.e., the cell

sap has more negative water potential). Thus, water moves from the region of higher water potential towards the region of lower water potential.

Non-osmotic theory: It was proposed by Thimann (1951) and Kramer (1959). It has been observed that absorption of water still occurs, if the concentration of cell sap in the root hair is lower than that of the soil water, or water is absorbed against concentration gradient (i.e., from higher DPD to lower DPD). Such type of water absorption occurs on the expense of energy obtained from respiration.

Following evidences support the view that energy is utilized during active absorption of water :

- (i) Rate of water absorption is directly proportional to the rate of respiration.
- (ii) Respiratory inhibitors such as KCN, which inhibit the absorption of water.
- (iii) Auxins (growth hormones), which increase respiration also promote water absorption.
- (iv) Wilting of plants occur in non-aerated soils such as water logged soils, as roots fail to absorb water in absence of respiration.
- (2) **Passive absorption :** It is the most common and rapid method of water absorption. The factor responsible for water absorption is present somewhere else than roots. It accounts for about 98% of the total water uptake by plant.

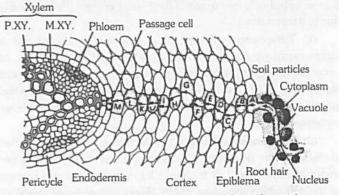

Fig: 4.1-4 Passive absorption of water through root hair

According to this theory, the forces responsible for absorption of water originate not in the cells of roots but in the cells of transpiring shoots. The root cells remain passive.

Due to transpiration, the DPD of mesophyll cells in the leaves increases which causes absorption of water by these cells from the xylem vessels of leaves. As the water column is continuous from leaves to roots, this deficit is transmitted to the xylem elements of roots and finally to root hairs through pericycle, endodermis and cortex. In this way water is continuously absorbed due to transpiration pull created in the leaves. This type of water transport occurs mainly through the apoplast in cortex but through the symplast in endodermis and pericycle.

The path of water from soil upto secondary xylem is :

Soil \rightarrow Root hair cell wall \rightarrow Cortex \rightarrow Endodermis \rightarrow Pericycle \rightarrow Protoxylem \rightarrow Metaxylem.

Factors affecting rate of water absorption: The different factors which influence the rate of water absorption by a plant can be divided into external or environmental and the internal factors.

External or Environmental factors

The amount of soil water: It is optimum at field capacity. Water absorption decreases above it. It begins to decline and stops at PWP.

Concentration of the soil solution: If the concentration of solutes increases in the soil water, its OP also increases which slows down or even inhibits the absorption of water. It happens due to addition of enough fertilizers in the soil increasing its salinity. This is popularly called as physiological dryness.

Soil aeration: Water absorption is done more efficiently in well aerated soil. Any deficiency of oxygen stops the respiration of roots and causes accumulation of CO_2 thus the protoplasm becomes viscous and the permeability of plasma membrane decreases. Due to all these factors the rate of water absorption is reduced. This is the reason for death of plants in flooded areas.

Soil temperature : The optimum temperature for maximum rate of water absorption ranges between $20^{\circ}C$ and $30^{\circ}C$. Too high temperature kills the cells. At very low temperatures ($4^{\circ}C$) water absorption is reduced or stopped and about $0^{\circ}C$ it is almost checked.

Transpiration: The rate of absorption of water is almost directly proportional to the rate of transpiration. A higher rate of transpiration increases the rate of water absorption.

Internal factors

Efficiency of the root system: A plant with deep and elaborate root system can absorb more water. The number of root hairs will be more in a highly branched and elaborate root system, thus its more surface area will be in contact with water.

In gymnosperms, the root hairs are absent, even then they are able to absorb water due to presence of mycorrhizal hyphae.

In epiphytes (orchid), the roots develop a special type of hygroscopic tissue called as velamen which can absorb atmospheric moisture.

Metabolic activity of roots: The poor aeration or use of metabolic inhibitors (e.g., KCN) inhibits the rate of water absorption. The metabolic activities help in proper growth of root system and generation of energy for absorption of certain vital minerals.

Absorption of water through leaves: Many species of plants can absorb atleast limited amounts of water through the leaves. Temporary immersion of aerial organs in flood waters takes place in some cases. Also the aerial organs of plants frequently become wet as a result of fog, dew or rain. Most of the water enters through the epidermal cells, although in some species hairs and specialized epidermal cells provide regions of high permeability. In general water absorption is more rapid in young leaves than in old leaves of the same plant.

Ascent of sap

The upward transport of water along with dissolved minerals from roots to the aerial parts of the plant is called Ascent of sap'. It is also called translocation of water. The water with dissolved minerals is called sap.

Path of ascent of sap: It is now well established that the ascent of sap takes place through xylem. In herbaceous plants almost all the tracheary elements participate in the process, but in large woody trees the tracheary elements of only sap wood are functional. Further, it has been proved experimentally that sap moves up the stem through the lumen of xylem vessels and tracheids and not through their walls.

Theories of ascent of sap: The various theories put forward to explain the mechanism of ascent of sap in plants can be placed in following three categories:

- (1) Vital force theories
- (2) Root pressure theory
- (3) Physical force theories
- (1) **Vital force theories:** According to these theories the forces required for ascent of sap are generated in living cells of the plant. These theories are not supported by experimental evidences hence they have been discarded. Some of the important vital force theories are mentioned below:

According to Westermaier (1883), ascent of sap occurs through xylem parenchyma; tracheids, and vessels only act as water reservoirs.

Relay pump theory (Clambering theory): According to Godlewski (1884) ascent of sap takes place due to rhythmatic change in the osmotic pressure of living cells of xylem parenchyma and medullary rays and are responsible for bringing about a pumping action of water in upward direction. Janse (1887) supported the theory and showed that if lower part of the shoot is killed upper leaves were affected.

Criticism

- (i) Strasburger (1891) and Overton (1911) used poisons (like picric acid) and excessive heat to kill the living cells of the plant. When such twigs were dipped in water, ascent of sap could still occur uninterrupted. This definitely proved that no vital force is involved in ascent of sap.
- (ii) Xylem structure does not support the Godlewski's theory. For pumping action living cells should be in between two xylem elements and not on lateral sides as found.

Pulsation theory: Sir J.C. Bose (1923) said that living cells of innermost layer of cortex, just outside the endodermis are in rhythmatic pulsations. Such pulsations are responsible for pumping the water in upward direction. According to Bose, the pulsatory cells pump the water into vessels.

Criticism: Dixon failed to verify the results of Bose. It has been estimated that sap should flow through 230–240 pulsating cells per second to account for normal rate of pulsations. This rate is several times higher as would be possible to the Bose theory (Shull, MacDougal, Benedict).

(2) Root pressure theory: It was proposed by Priestley (1916). According to this theory the water, which is absorbed by the root-hairs from the soil collects in the cells of the cortex. The cortical cells become fully turgid. In such circumstances the elastic walls of the cortical cells, exert pressure on their fluid-contents and force them towards the xylem vessels. Due to this loss of water these cortical cells become flaccid, again absorb water, become turgid and thus again force out their fluid contents. Thus the cortical cells of the root carry on intermittent pumping action, as a result of which considerable pressure is set up in the root. This pressure forces water up the xylem vessels. Thus the pressure, which is set up in the cortical cells of the roots due to osmotic action, is known as the root pressure. This term was used by Stephan Hales. According to Style, root pressure may be defined as "the pressure under which water passes from the living cells of the root in the xylem".

Objections

- (i) Taller plants like *Eucalyptus* need higher pressure to raise the water up. While the value of root pressure ranges from 2-5 atmospheres, a pressure of about 20 *atm*. is required to raise the water to tops of tall trees.
 - (ii) The absence of root pressure, ascent of sap continues.
- (iii) Plants growing in cold, drought or less aerated soil, root pressure fails to appear and transport of water is normal.

In gymnosperms root pressure has rarely been observed.

(3) Physical force theories: According to these theories the ascent of sap is purely a physical process. Some of the physical force theories are mentioned below:

Capillary force theory: It was proposed by Boehm (1809). According to him, in the fine tubes, the water rises as a result of surface tension to different heights depending on the capillarity of the tube. The finer the tube, the greater will be the rise of water in it. But the xylem vessels are sometimes broader than the capillarity range, and hence the rise due to surface tension will be negligible.

Objections

- (1) For capillarity a free surface is required.
- (2) Atmospheric pressure can support a column of water only upto the height of 34 feet.
- (3) Water can rise only upto the height of one meter in xylem vessels having diameter of 0.03mm.
 - (4) In gymnosperms usually the vessels are absent.

Imbibitional theory: It was proposed by Unger (1868) and supported by Sachs (1879). According to them, water moves upward in the stem through the walls of the xylem vessels. This theory is not accepted now because it is proved that water moves through the lumen of the xylem vessels and tracheids.

Atmospheric pressure theory: Due to the loss of water by transpiration, the leaves draw water from the xylem vessels through osmotic pressure. The atmospheric pressure acting on the water in the soil forces the water to rise up in the xylem vessels to fill the vacuum. But the atmospheric pressure can force the water to a height of only 10 meters. So it is evident that atmospheric pressure alone cannot force water to a height of 100 metres or more.

Jamin's chain theory: In xylem, water and air bubbles are found alternately. Thus upward movement occurs.

Cohesion of water and transpiration pull theory: This is the most widely accepted theory put forth by Dixon and Jolly in 1894, and further supported by Renner (1911, 1915), Curtis and Clark (1951), Bonner and Golston (1952), Kramer and Kozlowski (1960).

It is also known as Dixon's cohesion theory, or cohesion-tension theory.

This theory depends on the following assumptions:

(1) The xylem vessels are connected with each other, thus the water in them is in a continuous column from the root hairs to the mesophyll cells.

Walls of tracheids and vessels of xylem are made up of lignin and cellulose and have strong affinity for water (adhesion). The cell wall of adjacent cells, and those between the cells and xylem vessels all through the plant do not affect the continuity of the water column.

- (2) Due to the transpiration from leaves, a great water deficit takes place in its cells. As a result of this deficit the water is drawn osmotically from the xylem cells in leaf veins, and by the cells surrounding the veins. Thus a sort of pull is produced in the uppermost xylem cells in the leaves. It is called as the transpiration pull.
- (3) The water molecules have a great mutual attraction with each other or in other words we can say that they have tremendous cohesive power which is sometimes as much as 350 atmospheres. Thus the transpiration pull develops a negative pressure in the uppermost xylem cells. It is transmitted from there into the xylem of stems, and from there to the roots.

In this way the water rises due to the transpiration pull and the cohesive power of water molecules from the lowest parts of the roots to the highest peaks of the trees. The osmotic pressure in the transpiring leaf cells often reaches to 30 atmospheres whereas only 20 atmospheres are needed to raise the water to the tops of highest known trees.

Cuticular

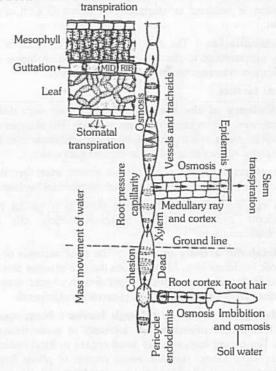

Fig: 4.1-5 Path of ascent of sap showing transpiration pull

Objections: This is the most generally accepted theory, yet there are some objections against it which it fails to explain.

The most important objection is that leaving smaller plants, the water column has been found to contain air bubbles, and so their continuity breaks at such places. This phenomenon is known as cavitation and has been demonstrated by Milburn and Johnson (1966). However, Scholander overruled this problem by suggesting that continuity of water column is maintained due to presence of pits in the lateral walls of xylem vessels.

Velocity of ascent of sap: Huber and Schmidt (1936) calculated the velocity of ascent of sap using radioactive ³²P, specific dyes and also by heat-pulse transport between two specific points of stem. It varies between 1 and 6 meters per hour but under high transpirational conditions, it may be as high as 45 meters per hour. It is more in ring porous woods having large vessels. It is slowest in gymnosperms.

Transpiration

"The loss of water in the form of vapours from the aerial parts of a plant is called transpiration". Maximum transpiration occurs in mesophytic plants.

About 98 percent of the water absorbed by land plants evaporates from the aerial parts and diffuse into the atmosphere.

Table : 4.1-1
Differences between transpiration and evaporation

S.No.	Transpiration	Evaporation
(1)	It is a physiological process and occurs in plants.	It is a physical process and occurs on any free surface.
(2)	The water moves through the epidermis with its cuticle or through the stomata.	Any liquid can evaporate. The living epidermis and stomata are not involved.
(3)	Living cells are involved.	It can occur from both living and non-living surfaces.
(4)	Various forces (such as vapour pressure, diffusion pressure, osmotic pressure, etc) are involved.	Not much forces are involved.
(5)	It keeps the surface of leaf and young stem wet and protects from sun burning.	It causes dryness of the free surface.

- (1) **Magnitude of transpiration**: A tropical palm under well watered conditions may lose as much as 500 litres of water per day. Daily loss of water by an apple tree may be 10-20 litres. A maize plant may lose 3-4 litres of water per day.
- (2) **Types of transpiration :** Most of the transpiration takes place through the leaves. It is called foliar transpiration. Stems transpire very little. Transpiration from stem is called cauline transpiration. Transpiration is of four types –
- (i) Cuticular transpiration: Cuticle is a layer of wax like covering on the epidermis of leaves. If it is thin, upto 20 percent of the total transpiration may take place through it, but with the increase in its thickness (e.g., in xerophytes), the water vapour loss is reduced.
- (ii) Lenticular transpiration: Loss of water vapours through lenticels is called lenticular transpiration. It amounts to about 0.1 percent of the total water loss through transpiration.
- (iii) **Stomatal transpiration**: The loss of water vapour, which occurs through specialized pores on leaf surface (stomata) is called stomatal transpiration. It amounts 80-90 percent of the total water vapour loss from the plants. It is the most common type of transpiration.
- (iv) Bark transpiration: This type of transpiration occurs through corky covering of the stems. Bark transpiration is very little but its measured rate is often more than lenticular transpiration due to larger area. The amount is 0.5% of the total transpiration.

(3) **Structure of stomata**: Stomata are the microscopic openings most commonly found in the leaves. These may be present in young stems and sometimes even in fruits (e.g., citrus, banana, cucumber, etc.). Each stomatal opening is surrounded by two specialized epidermal cells, called as the guard cells.

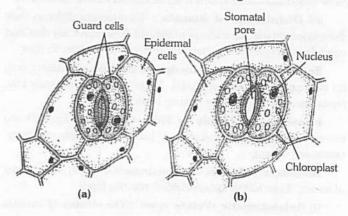

Fig: 4.1-6 Stomatal apparatus (a) Closed (b) Open

Because of their small size, the guard cells are rapidly influenced by turgor change and thus regulate the opening and closing of stomata. The guard cells of dicot leaves are kidney-shaped or raniform whereas those of monocots (family Gramineae) are dumbel-shaped or elliptical. The guard cells are surrounded by epidermal cells called as the accessory cells or subsidiary cells. These are different from the normal cells of epidermis having chloroplasts. These are also different from other cell as these develop from same cell from which guard cells develop. The stoma with subsidiary cells is called stomatal apparatus. Each stoma leads into a air space called sub stomatal cavity. Each guard cell has a thin layer of cytoplasm along the cell wall and a large vacuole. Its cytoplasm contains a distinct nucleus and several chloroplasts. The cell wall of guard cells around the stomatal pores are thickened and elastic due to presence of a secondary layer of cellulose.

The average length of stomata is $20-28\mu m$ and breadth $3-10\mu m$. The size of stomatal pore varies from species to species for example of fully opened stomatal pore of Zea mays measures $26\mu m$ long and $4\mu m$ wide.

- (4) Number of stomata on leaves: The number of stomata is not equal on both surface of leaves in different plants. Number of stomata per square cm is 1,000-60,000 or $10-600/mm^2$ in different plants sps.
- (5) **Types of stomata**: On the basis of orientation of subsidiary cells around the guard cells, Metcalfe and Chalk classified stomata into following types:

Anomocytic: The guard cells are surrounded by a limited number of unspecialized subsidiary cells which appear similar to other epidermal cells. *e.g.*, in Ranunculaceae family.

Anisocytic: The guard cells are surrounded by three subsidiary cells, two of which are large and one is very small. e.g., in Solanaceae and Cruciferae families.

Paracytic: The guard cells are surrounded by only two subsidiary cells lying parallel to the guard cells *e.g.*, Magnoliaceae family.

Diacytic: The guard cells are surrounded by only two subsidiary cells lying at right angles to the longitudinal axis of the guard cells. e.g., Acanthaceae and Labiatae families.

Actinocytic: The guard cells are surrounded by four or more subsidiary cells and which are elongated radially to stomata.

(6) Distribution of stomata: The stomata differ in their distribution on the two surfaces of the leaf. The leaves are classified into following types on the basis of stomatal distribution on them:

Epistomatic (Water Lily type): Stomata are present only on the upper epidermis of leaves. These are found in water Lily, Nymphaea and many other floating hydrophytes.

Hypostomatic (Apple or Mulberry type): Stomata are present only on the lower surface of leaves. *e.g.*, Apple, mulberry, peach and walnut.

Amphistomatic : Stomata are present on both the surfaces of leaves. It can further be subdivided into two types :

- (i) **Anisostomatic (Potato type):** The number of stomata is more on the lower surface and less on the upper surface. In other words, the lower surface is multistomatic and the upper surface is paucistomatic. Such leaves are also called as dorsiventral leaves. *e.g.*, Potato, tomato, bean, pea, and cabbage.
- (ii) **Isostomatic (Oat type)**: The stomata are equally distributed on both the surfaces of leaves. These leaves are also called as isobilateral leaves. These are found in monocots *e.g.*, Oat, maize, grasses, etc.

Astomatic (**Potamogeton type**): Stomata are either absent altogether or vestigial. e.g., Potamogeton and submerged hydrophytes.

(7) **Daily periodicity of stomatal movement**: Loftfield (1921) classified the stomata into four types, depending upon the periods of opening and closing.

Alfalfa type (Leucerne type): The stomata remain open throughout the day but close during night, e.g., Pea, bean, mustard, cucumber, sunflower, radish, turnip, apple, grape.

Potato type: The stomata close only for a few hours in the evening, otherwise they remain open throughout the day and night e.g., Cucurbita, Allium, Cabbage, Tulip, Banana etc.

Barley type: These stomata open only for a few hours in the day time, otherwise they remain closed throughout the day and night, e.g., Cereals.

Equisetum type: The stomata remain always open through out the day and night. *e.g.*, Amphibious plants or emergent hydrophytes.

(8) Mechanism of opening and closing of stomata (Stomatal movement): Opening and closing of stomata occurs due to turgor pressure changes in guard cells. The transpiration is regulated by the movement of guard cells of stomata.

Several theories have been put forth to explain the opening and closure of stomata. Which have been discussed below:

Photosynthetic theory: According to Von Mohl (1856) the chloroplasts present in guard cells prepare osmotically active substances by photosynthesis. As a result, their osmotic pressure increases and their turgor pressure increases due to endosmosis. This results in opening of stomata.

Objection: In many cases, chloroplasts of guard cells are poorly developed and incapable of performing photosynthesis.

Starch \Rightarrow **sugar interconversion theory**: According to Lloyd (1908), turgidity of guard cell depends upon interconversion of starch and sugar. This fact was supported by Loftfield (1921) who found that guard cells contain sugar during day time when they are open and starch during night when they are closed. Later Sayre (1926) observed that stomata open in neutral or alkaline pH which prevails during day time due to constant removal of CO_2 by photosynthesis. They remain closed during night when there is no photosynthesis and due to accumulation of CO_2 , carbonic acid is formed which causes the pH to be acidic, Sayre thus proposed that interconversion of starch and sugar is regulated by the pH. Sayre's hypothesis was supported by Scarth (1932) and Small et.al (1942). This hypothesis was further supported by detection of the enzyme phosphorylase in guard cells by Yin and Tung (1948). This enzyme is responsible for starch-glucose interconversion.

$$\begin{array}{ccc} \text{Starch} + \text{Pi} & \xrightarrow{\text{Phosphorylase, } pH = 7 \text{ (Day)}} & \text{Glucose} - 1 - \text{phosphate} \\ & & pH = 5 \text{ (Night)} \end{array}$$

Criticism

- (1) Starch ≠ Sugar interconversion is a slow process which can not account for rapid stomatal movement.
- (2) Starch or other polymerised polysaccharide do not occur in onion plant where stomatal movement occurs.
- (3) Glucose is not detectable in the guard cells when stomatal opening occurs.
- (4) The theory could not explain the extra-effectiveness of blue light at the time of stomatal opening.

Stewards modification: Steward (1964) said that glucose-Iphosphate should be further converted into glucose as glucose-Iphosphate is not capable of changing osmotic pressure. In this
process of stomatal opening and closing, enzymes like
phosphorylase, phosphoglucomutase, phosphatase and hexokinase
are present in guard cells.

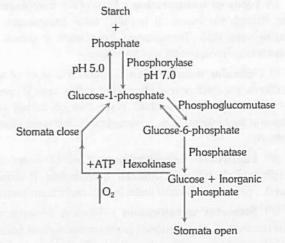

Fig: 4.1-7 Mechanism of opening and closing of stomata according to Steward

Glycolate theory: Zelitch (1963) proposed that stomata open due to production of glycolic acid by photorespiration in guard cells under low concentration of CO_2 . The glycolic acid thus produced is converted into soluble carbohydrates which increase the O.P. of guard cells.

Objections

- (1) It fails to explain the opening of stomata in dark (e.g., in succulents).
- (2) In some plants stomata have been found to remain closed even during day times.
- (3) It fails to explain the effect of blue light on stomatal opening.

Active K^+ ion transport theory: Imamura (1943) and many other scientists found accumulation of K^+ in the guard cells when they are exposed to light. This was initially given by Fujino (1959) and later modified by Levitt (1974). This theory suggests that stomatal opening and closing occurs due to an active transport of K^+ into or out of the guard cells.

Proton transport theory: It was proposed by **Levitt** (1974). According to this theory stomatal opening and closing can be explained in the following manner:

Mechanism of stomatal opening

- (1) During day time due to rapid rate of photosynthesis, the concentration of CO_2 decreases in the guard cells. As a result their pH is increased. At higher pH, starch in the guard cells is converted into organic acid by the enzyme phosphoenol pyruvate carboxylase (PEPC). This enzyme was discovered by Willmer etal. (1973). It can convert several other carbohydrates into organic acids.
- (2) The organic acid (e.g., malic acid) dissociates into H^+ ions (protons) and malate ions.
- (3) The protons (H^+) are actively transported into subsidiary cells in exchange for K^+ with the help of an energy (ATP) driven H^+ - K^+ -pump. The uptake of K^+ -ions is balanced by uptake of CI and the negative charge on malate-ions.
- (4) Increased concentration of K^+ and malate ions in the guard cells increases the O.P. of guard cells.
- (5) Water enters from adjoining subsidiary cells by endosmosis.
- (6) Turgor pressure of guard cells increases. Turgidity of guard cell is controlled by potassium, chloride and malate.
 - (7) Stomata open.

Mechanism of stomatal closure: According to **Cowan** *et.al.* (1982) closure of stomata depends upon abscisic acid (ABA) which is in fact an inhibitor of K^+ -uptake. It becomes functional in presence of CO_2 or in acidic conditions (low pH).

- (1) During night photosynthesis stops which results in increased concentration of CO_2 which causes lowering of pH.
- (2) At lower pH, ABA inhibits K⁺-uptake by changing the permeability of guard cells.
- (3) The K^+ -ions now start moving out of the guard cells which results in lowering of the pH.
- (4) At low pH, organic acids are converted back into starch by PEPC.
- (5) The O.P. of guard cells decreases and water moves out of them into subsidiary cells by the process of exosmosis, thus decreasing their turgor pressure.
 - (6) The guard cells become flaccid and the stomata close.

Stomatal opening in succulent plants (Scotoactive stomata): The stomata in succulent plant or CAM plants (like Opuntia, Bryophyllum etc.) open during night (darkness) and remain closed during the day time and found in lower surface. This type of stomatal opening is called 'Scotoactive type' and the stomata which open during day are called as photoactive. Stomata closed and open due to the activity of water. This type of stomata is known as hydroactive stomata. The opening and closing mechanism of scotoactive stomata was explained by Nishida (1963). In succulent plants, during night, there is incomplete oxidation of carbohydrates and accumulation of organic acids (e.g., malic acid) without release of CO_2 . During day time the accumulated organic acids breakdown rapidly releasing excess amount of CO_2 for photosynthesis as well as to keep the stomata closed.

During night: $2C_6H_{12}O_6 + 3O_2 \rightarrow 3C_4H_6O_5 + 3H_2O_6$

During day: $C_4H_6O_5 + 3O_2 \rightarrow 4CO_2 + 3H_2O$.

Factors affecting rate of transpiration

External factors

Atmospheric humidity: If the atmosphere is humid, it reduces the rate of transpiration. When the air is dry, the rate of transpiration increases.

Temperature: It affects the rate of transpiration only indirectly. Increase in the temperature of the air decreases the humidity of the air and therefore more water is vapourised and lost from the transpiring surface.

Light: Light affects the rate of transpiration due to its effect on temperature and photosynthesis. During daytime stomata open wide but during night they close. Thus increased temperature and presence of wide open stomata increase the rate of transpiration. Light is the most important factor in the regulation of transpiration.

Maximum opening of stomata occurs in red light (660 nm), followed by blue light (445 nm) and no opening occurs in green light, UV light and far red light.

Atmospheric pressure : The rate of transpiration is inversely proportional to the atmospheric pressure.

Available soil water: If the available water in the soil is not sufficient the rate of transpiration is decreased. Under internal water deficiency the stomata are partially or completely closed.

Wind velocity: A transpiring surface of leaf continuously adds water vapours to the atmospheric air. Once the immediate area becomes saturated, it reduces the rate of transpiration. Wind velocity removes the air of that area, which is replaced by fresh air and result in an increase in the rate of transpiration. Wind velocity is measured by anemometer.

 ${\it CO_2}$ concentration: Reduced ${\it CO_2}$ conc. favours opening of stomata while an increase in ${\it CO_2}$ conc. promotes stomatal closing.

Transpiration depends upon difference in vapour pressure of internal atmosphere of leaf and external environment (i.e., V.P. gradient) and it is therefore, that no transpiration occurs when stomata are fully open but relative humidity is 100%.

Internal factors/Plant factors

Leaf area : If leaf area is more, transpiration is faster. However, the rate of transpiration per unit area is more in smaller leaves than in larger leaves due to high number of stomata in a small leaf. Number of stomata per unit area of leaf is called stomatal frequency.

$$I = \frac{S}{E+S} \times 100$$
 here, $I = Stomatal index$

S = No. of stomata per unit area

E = No. of epidermal cells in unit area.

Leaf structure: The anatomical features of leaves like sunken or vestigial stomata; presence of hair, cuticle or waxy layer on the epidermis; presence of hydrophilic substances such as gums, mucilage *etc.* in the cells; compactly arranged mesophyll cells etc. help in reducing the rate of transpiration.

Root shoot ratio: According to Parker (1949) the rate of transpiration is directly proportional to the root-shoot ratio.

Age of plants: Germinating seeds show a slow rate of transpiration. It becomes maximum at maturity. However, it decreases at senescence stage.

Orientation of leaves : If the leaves are arranged transversely on the shoot they lose more water because they are exposed to direct sunlight. If placed perpendicularly they transpire at slower rate.

Significance of transpiration : The advantages and disadvantages of transpiration are discussed below :

Advantages

- Transpiration is important for plants because it directly influences the absorption of water from the soil.
- (2) Transpiration exerts a tension or pull on water column in xylem which is responsible for the ascent of sap.
- (3) Transpiration helps in the movement of water and minerals absorbed by the roots to the other parts of the plant.
- (4) The evaporation of water during transpiration contributes to the cooling of leaves (and also the surrounding air) and protects leaves from heat injury particularly under conditions of high temperature and intense sunlight.

Disadvantages

- Transpiration often results in water deficit which causes injury to the plants by desiccation.
- (2) Rapid transpiration causes mid-day leaf water deficit (temporary wilting). If such condition continues for some time, permanent water deficit (permanent wilting) may develop, which causes injury to plants.
- (3) Many xerophytes have to develop structural modifications to reduce transpiration. These modifications are extra burden on the plants.
- (4) Excessive rate of transpiration leads to stunted growth of plants.

(5) Since approximately 90 percent of absorbed water is lost through transpiration, the energy used in absorption and conduction of water goes waste.

Curtis (1926) truely called 'transpiration as a necessary evil'.

Anti-transpirants: 'The chemical substances which reduce transpiration (by increasing leaf resistance to water vapour diffusion) without affecting gaseous exchange, are called anti-transpirants'. Anti-transpirants are of two types metabolic inhibitors and film forming anti-transpirants.

Metabolic inhibitors: They reduce transpiration by causing partial closure of stomata without influencing other metabolite processes, the most important of these inhibitors are phenyl mercuric acetate (PMA), and abscissic acid (ABA).

Film forming anti-transpirants: They check transpiration by forming a thin transparent film on the transpiring surface. They are sufficiently permeable to carbon dioxide and oxygen to allow photosynthesis and respiration, but prevent movement of water vapour through them. The important chemicals of this group are silicon emulsion, colourless plastic resins and low viscosity waxes.

Guttation: The process of exudation of liquid drops from the edges of leaves (during night or early morning) is called guttation or the process of the escape of liquid from the tip of uninjured leaf is called guttation. It was first studied by Bergerstein in 1887. Usually it occurs through stomata like pores called hydathodes (Water Stomata). Exudation may sometime occur from stem through the scars of leaves and lenticles. Guttation usually occurs when the plant is put in more saturated atmosphere.

Hydathode pore

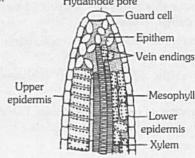

Fig: 4.1-8 Vertical section of a leaf showing hydathode

Hydathodes are generally present at the tip or margin of leaves. These pores are present over a mass of loosely arranged cells with large intercellular spaces called epithem. This mass of tissue lies above a vein ending. The xylem of a small vein usually terminates among the thin walled parenchymatous cells of epithem. Guttation is caused due to root pressure. It is found in 115 families and 333 genera of woody and herbaceous plants. e.g., Garden nasturtium (*Tropeolum*), Oat (*Avena*), *Colocasia* etc. growing in moist, warm soil and under humid conditions. When the absorption of water exceeds that of the transpiration, hydrostatic pressure is built up in xylem ducts. As a result, water is pushed in the xylem ducts and comes out through the hydathodes. The water of guttation contains several dissolved inorganic and organic substance.

Translocation of organic solutes

"The movement of organic food or solute in soluble form, from one organ to another organ is called translocation of organic solutes."

The process of translocation requires expenditure of metabolic energy and the solute moves at the rate of 100 cm/hr.

Directions of translocation

Downward translocation: It is of most important type, i.e., from leaves to stem and roots.

Upward translocation : From leaves to developing flowers, buds, fruits and also during germination of seeds and tubers, etc.

Radial translocation: From pith to cortex and epidermis, Path of translocation

- (1) **Downward translocation of organic solutes :** Phloem is the path for downward translocation of organic food. Following evidences are in support of it :
- (i) Elimination of other tissues: Xylem is responsible for upward movement of water and minerals, so it cannot account for downward translocation of solute at the same time. Thus only phloem is left (where there is end to end arrangement of sieve tubes united by sieve pores). Which is responsible for translocation of solutes in downward direction.
- (ii) Chemical analysis of phloem sap and xylem sap: Chemical analysis of sieve tube sap proves that concentrated solution of sucrose is translocated from the place of synthesis to other parts of the plant body. Glucose and fructose are sometimes found in traces only. The amount of sucrose is more in phloem sap during the day and less in night. In xylem the amount of sucrose is in traces and also there is no diurnal fluctuation.
- (iii) **Blocking of phloem**: Blocking of sieve pores by 'callose' during winter blocks translocation of solutes.
- (iv) Ringing or Girdling experiment: It was first performed by Hartig (1837). On removing the ring of bark (phloem + cambium) above the root at the base of stem, accumulation of food occurs in the form of swelling just above the ring, which suggests that in absence of phloem, downward translocation of food is stopped.
- (v) **Structure of phloem**: The structure of phloem tissue is well modified for conduction of solutes. Phloem tissue of an angiosperm consists of sieve tubes, companion cells several kinds of parenchyma cells, fibres and scleroids. Of these sieve tubes are involved in sugar translocation.
- (2) Upward translocation of organic solutes: According to Curtis upward conduction of foods also takes place through phloem.

Mechanism of translocation

Diffusion hypothesis: Mason and Maskel (1928) working on cotton plant demonstrated that the translocation of foods occurs from the place of high concentration (place of manufacture or storage) to the place of lower concentration (place of consumption) but it is very slow process so Mason and Phillis (1936) modified this concept and proposed activated diffusion hypothesis. According to this concept the food particles are first energy activated then translocated. This hypothesis is not accepted due to lack of experimental evidence.

Protoplasmic streaming hypothesis: This concept was proposed by de Vries (1885). According to him the food is transported across by streaming current of protoplasm. The cell protoplasm shows a special locomotion movement called cyclosis. It is of two types, rotation and circulation. While rotation is circular movement of protoplasm, circulation is radial movement forming eddies around the vacuoles. The hypothesis involves two phenomenon, such as streaming of sieve protoplasm and diffusion of metabolites through sieve pores.

This hypothesis not only explains faster rate of translocation but also the bidirectional movement of metabolites across a single sieve element. This hypothesis was supported by Curtis (1950).

Transcellular streaming: Thaine (1964) suggested modification to cytoplasmic streaming theory. He defined transcellular streaming as "the movement of the particulate and fluid constituents of cytoplasm through linear files of longitudinally oriented plant cells. "He further proposed that transcellular strands are proteinaceous and characteristic microtubules to afford rhythmic contraction. Thus, transcellular streaming is an attractive mechanism as it would explain the phenomenon of bidirectional translocation.

Electro-osmotic hypothesis: A mechanism involving electro-osmosis was proposed independently by Fensom (1957) and Spanner (1958). According to this hypothesis the solute moves in the positive direction of the electrical gradient along with K^+ ions.

Munch's mass flow or pressure flow hypothesis: The mass flow or pressure flow mechanism was first proposed by Hartig (1860). It was later modified by Munch (1930). Crafts elaborated it further in 1938. Munch assumed that the protoplasm of sieve tube is connected through plasmodesmata and forms a continuous system, called as the symplast. The translocation of solutes occurs in a mass alongwith cell sap through the sieve tubes from a region of higher turgor pressure to low turgor pressure (i.e., along a turgor pressure gradient).

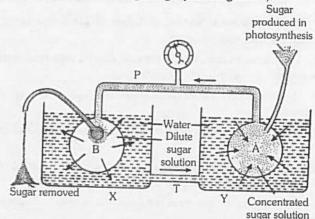

Fig: 4.1-9 A model demonstrating the Munch mass flow hypothesis

Munch's hypothesis has been supported further by the following:

When a woody or herbaceous plant is girdled, the sap containing high sugar content exudates from the cut end. Positive concentration gradient disappears when the plants are defoliated. Movement of viruses and growth hormones is fast in illuminated leaves as compared to shaded leaves.

Objections:

The hypothesis fails to explain bidirectional movement of metabolites which is common in plants. Osmotic pressure of mesophyll cells and that of root hair do not confirm the requirements. Munch's hypothesis gives a passive role to the seive tube elements and the protoplasm.

Factors affecting translocation

Temperature: Optimum temperature for translocation ranges between 20-30°C. The rate of translocation increases with the increase of temperature upto an upper limit and then starts declining. At low temperature, the rate of translocation decreases.

Light : Hartt and his coworkers (1964) proposed that the movement of assimilates of a leaf can depend upon radiant energy. The increase in light intensity more food starts being translocated to roots than to shoots. At lower intensity the growth of root and shoot is inhibited thereby the rate of translocation also decreases.

Hormones : Cytokinins have a pronounced effect on the translocation of water soluble nitrogen compounds.

Oxygen: Oxygen is necessary during transfer of food from mesophyll cells into phloem which is called as phloem loading.

Minerals: Boron is highly essential for translocation of sugar. Phosphorus also helps in translocation of solutes.

Water: Translocation of photosynthates out of the leaves is highly sensitive to the amount of water in the plant cells.

Metabolic inhibitors: The metabolic inhibitors which inhibit the process of respiration (e.g., iodoacetate, HCN, carbon monoxide etc.) adversely affect the process of translocation because phloem loading and unloading require ATP.

Tips & Tricks

- Stephen Hales is known as father of plant physiology.

 Coined the term root pressure.
- The osmotic pressure of a solution can be measured with the help of a apparatus called osmometer.
- Molar solution: 1gm mole of solute plus 1 litre / 1000cc of solution.
- Cryoscopic osmometer measures the osmotic potential of solution by measuring its freezing point.
- The amount of water left in the soil after the plant has permanently wilted is the wilted coefficient.
- Humus and clay are two colloidal complexes of soil.
- Cohesive force is called as tensile strength of water.
- Manometer (Gk. manos thin, metron measure). An instrument for measuring pressure of tension (such as root pressure) in gases and liquids.

- Cohesive strength of 47-207 atm. in xylem sap is sufficient to meet the stress of transpiration pull, so that water column does not break.
- S Osmotic pressure is maximum in noon. At this time water contents in the cell are minimum.
- S Osmotic pressure is highest in halophytes.
- In night, root pressure will be maximum because in night transpiration is zero.
- Pressure bomb technique was used by Scholander et al.
- Psychorometer is used for measuring relative humidity as well as transpiration.
- Hydrometer is used for measuring the density or specific gravity of a liquid.
- Barometer is used for measuring atmospheric pressure.
- Barograph represents the recording of barometer.
- Porometer is used for measuring the size of stomata.
- Atmometer is used for measuring pull caused by evaporation of water from a porous pot.
- Potometer is used for measuring the rate of transpiration.
- Potometer works on the principle of amount of water absorbed equals the amount transpired.
- Transpiration on hills: High due to lower atmospheric pressure but low due to lesser hours of light and lower temperature. Transpiration is therefore, near normal but the plants show xeromorphy due to lesser water availability.
- ✓ In Saxifraga, the rate of guttation is high during flowering.
- Maximum opening of stomata occurs at about 10:00 AM and 3:00 PM (At 12:00 noon, partial closure of stomata occurs).
- In C₃ plant the rate of transpiration is high.
- Cobalt chloride paper method was first used by Stahl (1894). It is used to compare rate of transpiration on two surfaces of leaf. Cobalt chloride is blue in anhydrous state. In contact with water vapour it turns pink.
- ES Bleeding is the exudation of sap (water along with dissolved organic and inorganic substances) from the injured parts of the plant e.g., exudation of latex from laticiferous ducts in Euphorbia and members of family moraceae (mulberry family) are the cases of bleeding.
- When transpiration is very low and absorption is high, the root pressure is maximum.
- ✓ In aquatic and submerged plants stomata are absent e.g.,
 Vallisneria.
- Mittler (1958) develop a technique for the collection of phloem sap using an aphid stylet.
- The principle pathway by which water is translocated in angiosperm is xylem and vessels.

Ordinary Thinking

Objective Questions

General

1. The sugarcane plant has

[AIIMS 2004]

- (a) Dumb-bell shaped guard cells
- (b) Pentamerous flowers
- (c) Reticulate venation
- (d) Capsular fruits
- Some leaves are removed from the stem cuttings planted for 2. vegetative propagation. This is done
 - (a) To increase water uptake
 - (b) Because it helps in rooting of cuttings
 - (c) To reduce water loss
 - (d) Because the cuttings need less food
- 3. Exchange of substances between individual cells and their environments takes place by [BHU 2002]
 - (a) Osmosis
- (b) Diffusion
- (c) Active transport
- (d) All of these
- When a bark of tissue is cut from stem, of which 4. vascular tissue is removed
 - (a) Xylem
- (b) Phloem
- (c) Parenchyma
- (d) None of these
- 5. Best soil for healthy and vigorous growth of a plant is

[BVP 2004; CPMT 2010]

- (a) Sandy soil
- (b) Loam
- (c) Clay
- (d) None of these
- Soil formed after leaching and rich in Al and Fe is

[DPMT 2004]

- (a) Alluvial
- (b) Podosol
- (c) Laterite
- (d) None of these
- 7. Active transport of ions by the cell requires [MP PMT 2002]
- (a) High temperature
- (b) ATP
- (c) Alkaline pH
- (d) Salts
- 8. Good soil is

[CPMT 2004]

- (a) Which holds whole of the water that enters into it
- (b) Which allows percolating the water slowly from it
- (c) Which allows water to pass very quickly from it
- (d) Which allows limited amount of water to retain into it
- Lenticels and hydathodes are small pores with following common attributes [BHU 1994]
 - (a) Their opening and closing is not regulated
 - (b) They allow exchange of gases
 - (c) They always remain closed
 - (d) They are found on the same organ of plants
- 10. Which of the events is more rapid
 - (a) Suction of water and minerals due to transpiration pull
 - (b) Cyclosis in cell cytoplasm
 - (c) Sugar transport in phloem
 - (d) Distribution of hormones from one part to other

11. Attractive forces of cell walls for water molecules is termed as

[NCERT; Kerala PMT 2010]

- (a) Adhesion
- (b) Cohesion
- (c) Osmosis
- (d) Plasmolysis
- 12. In trees, death of protoplasts is essential for a vital function [BHU 1994]
 - (a) Stomatal movements
 - (b) Both water and food transport
 - (c) Water transport
 - (d) Food transport
- Which of the following is not a function of water in cell 13.

[RPMT 2002]

[RPMT 1999]

- (a) It provides energy for chemical reaction
- (b) It acts as a solvent
- (c) It provides a medium for chemical reaction
- (d) It releases hydrogen ions on ionisation
- 14. Active absorption is affected by
 - (a) Osmotic concentration
 - (b) Associate tissue structures
 - (c) Transpiration
 - (d) Sucking capacity of root hair
- Which one of the following doesn't help in molecule 15. transport [BHU 2003]
 - (a) Diffusion
- (b) Osmosis
- (c) Surface tension
- (d) Active transport
- Root cap has no function in water absorption, because
 - (a) Its vascular system is not directly connected
 - (b) Its cells are loosely placed
 - (c) It has cells without chloroplast
 - (d) It has no root hair
- 17. Water infiltration will be slowest in [AIEEE Pharmacy 2004]
 - (a) Black cotton soil
- (b) Sandy soil
- (c) Red soil
- (d) Loamy soil
- 18. Meaningful girdling (Ringing) experiments cannot be done on sugarcane because [CBSE PMT 1994]
 - (a) Phloem is present inside the xylem
 - (b) It can not tolerate the injury
 - (c) Vascular bundles are scattered
 - (d) Plants are very delicate
- The amount of water held by the soil after drainage is 19. known as [BHU 1999]
 - (a) Mineral water
- (b) Soil water
- (c) Field capacity
- (d) Gravitational capacity

Membranes, Osmosis, Diffusion, Imbibition, Plasmolysis and Wilting

- 1. Osmosis is the diffusion of
- [NCERT; Odisha JEE 2008]
- (a) Solute
- (b) Free energy
- (c) Water
- (d) Solute and solvent

2. The relationship $\pi v = nRT$ is not obeyed by

[Odisha JEE 2012]

- (a) Concentrated solution
- (b) Dilute solution
- (c) Extremely dilute solution (d) All of these
- That the cell membrane is selectively permeable can be best deduced by
 - (a) The entry of water from root hair
 - (b) The entry of mineral salts from the root hair
 - (c) Both together
 - (d) The rise of sap in plants
- 4. The cell wall is permeable and not a semipermeable structure can be best deduced from the passage of water and mineral salts from
 - (a) Soil into periplasmic space of root hairs
 - (b) Root hairs to cortical cells
 - (c) Cortical cells to pericycle
 - (d) Pericycle to trachea
- What happens when formalin preserved Spirogyra filament is placed in a hypertonic sugar solution
 - (a) It gains turgidity
- (b) It looses turgidity
- (c) It becomes plasmolysed (d) Nothing happens
- Selective permeability identifies the process of transmission through semipermeable membrane is called [AFMC 2003]

O

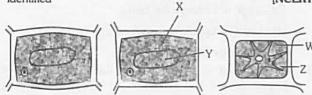

The movement of water from higher water potential to lower water potential through a semi-permeable membrane is called [J & K CET 2010; WB JEE 2016]

Or

Living cells placed in isotonic solution (0.9% saline) retain their size and shape. This is based on the concept of

[WB JEE 2012]

- (a) Diffusion
- (b) Osmosis
- (c) Plasmolysis
- (d) Imbibition
- 7. The process of osmosis involves
 - (a) Movement of solute through semipermeable membrane
 - (b) Movement of solvent through a semipermeable membrane
 - (c) Movement of solution through a semipermeable membrane
 - (d) None of the above
- 8. The given figure shows plasmolysis in cell. A is normal turgid cell, B shows incipient plasmolysis and C is plasmolysed cell. Select the right option in which W, X, Y and Z are correctly identified
 [NCERT]

- (a) Shrunken protoplast, Protoplast, Vacuole, Hypotonic solution
- (b) Shrunken protoplast, Flaccid protoplast, Vacuole, External solution
- (c) Turgid protoplast, Protoplast, Vacuole, External solution
- (d) Shrunken protoplast, Protoplast, Vacuole, External solution

9. Assume that an actively respiring cell has 3x number of K^+ in its cytoplasm and 2x number of K^+ outside. After sometime, x number of K^+ entered into the cell. What is the process by which K^+ transport has taken place

[EAMCET 2009]

- (a) Primary active transport
- (b) Secondary active transport
- (c) Diffusion
- (d) Passive transport
- 10. A RBC and a plant cell (with thick cell wall) are placed in distilled water. The solute concentration is the same in both the cells. What changes would be observed in them

[KCET 2009]

- (a) Both plant cell and RBC would not undergo any change
- (b) The RBC would increase is size and burst while the plant cell would remain about the same size
- (c) The plant cell would increases in size and burst while the RBC would remain about the same size
- (d) Both plant cell and RBC would decrease in size and collapse
- 11. In the process of osmosis

[AFMC 1995]

- (a) Both protoplasm and cell wall act as a single layer
- (b) Only protoplast acts as a single layer
- (c) Only cell membrane acts as a single layer
- (d) None of the above
- 12. A professor kept some moist seeds in an airtight jar and started lecturing. At the end of the experiment an explosion occurred in the jar. What did the professor want to explain

[CBSE PMT 1990]

- (a) Osmosis
- (b) Diffusion
- (c) Anaerobic respiration
- (d) Imbibition
- 13. Plant cell plasmolysed in a solution which is

[MP PMT 1998, 2006; Odisha JEE 2008]

If a cell is reduced in size on placing in a solution of sugar, the solution is [RPMT 2002; AFMC 2009]

- (a) Hypotonic
- (b) Hypertonic
- (c) Isotonic
- (d) Concentration no means
- 14. Osmosis is defined as the process in which [MP PMT 1998]
 - (a) Water diffuses from lower concentration to higher concentration
 - (b) Solutes diffuse from lower concentration to higher concentration
 - (c) Active transport of ions takes place
 - (d) Passive transport of ions takes place
- Graham's law is correlated with
 (a) Diffusion (b)
 - (b) Osmoregulation

[WB JEE 2009]

- (c) Osmosis
- (d) Adsorption
- 16. The first process by which water enters into the seed coat when a seed is placed in suitable environment for germination is

[Bihar MDAT 1995; KCET 2007; Kerala PMT 2011] Or

In seed germination, the first phenomenon take place is
[Bihar MDAT 1995]

- (a) Osmosis
- (b) Active transport
- (c) Absorption
- (d) Imbibition

Transport in Plants 599 Which of the following experiment is called physiological In the process of plasmolysis 29. [CPMT 1995] demonstration of osmosis [KCET 2007] (a) Endosmosis occurs (b) Exosmosis occurs (a) Thistle funnel - whose mouth is tied with egg (c) Imbibition occurs (d) Diffusion occurs membrane In the process of osmosis, volume of solvent [AFMC 1996] (b) Thistle funnel - whose mouth is tied with parchment (a) Increases paper (b) Decreases (c) Potometer (c) Remains same (d) Bell jar experiment 18. An example of selectively permeable membrane is (d) Volume is not related in osmosis (e) Endosmosis (a) Plasmalemma (b) Cell wall The membrane which allows passage of certain substances (c) Mitochondrial membrane (d) Chloroplast membrane more readily than others is termed as 19. Plasma membrane controls (a) Impermeable (a) Passage of water (b) Semisolid (b) Passage of water and some solutes in and out of the cell (c) Permeable (d) Selectively permeable 32. What shall be the sequence of events during wilting of a (c) Passage of water and solutes into the cell [Kerala CET 2002] (d) Movements of the cell contents out of the cell (a) Exosmosis, deplasmolysis, wilting 20. Which plant is used for demonstrating plasmolysis in the laboratory (b) Endosmosis, plasmolysis, wilting (c) Exosmosis, plasmolysis, wilting (a) Tropeolum (b) Impatiense balsamia (d) Endosmosis, deplasmolysis, wilting (c) Tradescantia (d) All the above 21. A plasmolysed cell can be deplasmolysed by placing it in Force developed in cortex of root which pushes water into xylem of root from soil [Odisha JEE 2005] **IBVP 20021** (a) Diffusion (a) Isotonic solution (b) Osmotic pressure (c) Turgor pressure (b) Hypertonic solution (d) Root pressure 22. Plant cells submerged in distilled water will become (c) Saturated solution IMP PMT 19981 (d) Pure water or hypotonic solution (a) Turgid (b) Flaccid What would happen if a thin slice of sugar beet is kept in 34. (c) Plasmolysed (d) Impermeable [CPMT 2002] 23. Process of osmosis shall cease when (a) It should lose water from the cell (a) Solutions become isotonic or DPD becomes equal (b) It should become turgid (b) Water concentration becomes equal (c) It should neither absorbed water nor lose it (c) There is no light (d) It should absorb water from the soil solution (d) The level of water falls 35. When a potato piece is kept in a highly concentrated salt Which of the following has more imbibition power solution, then [CBSE PMT 2002] (a) Cellulose (b) Hemicellulose (a) Potato is plasmolysed (c) Fat (d) Protein 25. Wilting occurs when (b) Potato is deplasmolysed [AFMC 2004, 08] (a) Rate of transpiration is higher than absorption (c) Potato cells get bursted (b) Rate of absorption is higher than transpiration (d) There is no effect due to isotonic solution (c) Excess root pressure Osmosis is helpful to plant because 36. (d) High relative humidity in air (a) Growth of the young cells is brought about by osmotic 26 When plant cells are kept in a concentrated salt solution, pressure and turgor pressure of these cells they are [MP PMT 1994; BVP 2004] (b) Certain turgor moments in plants are determined by (a) Deplasmolysed (b) Plasmolysed osmosis (c) Remains as such (d) Becomes turgid (c) Both (a) and (b) 27. The initial stage of water absorption by root cells is by (d) None of these In rainy season, the doors get wet due to 37. Dry seeds when placed in water swells due to [AIIMS 2001; GUJCET 2015] [NCERT; CPMT 1994] (a) Imbibition (b) Absorption (a) Adsorption (b) Absorption (c) Osmosis (c) Diffusion (d) Imbibition (d) Endosmosis The process by which large molecules move out of the cell is 38. Due to plasmolysis, the plant cell called [Kerala CET 1999; GUJCET 2014]

(a) Bursts

(c) Becomes turgid

(b) Swells up

(d) Becomes flaccid

(a) Plasmolysis

(c) Phagocytosis

(b) Deplasmolysis

(d) Reverse phagocytosis

- The plant undergoes wilting when [CPMT 1993, 94, 2002; AFMC 2005; RPMT 2005; BHU 2006; WB JEE 2009]
 - (a) Xulem is blocked
 - (b) Cambium is blocked
 - (c) Phloem is blocked
 - (d) Some roots are reduced in number
- In some plants, the leaves droop down during day while 40. become normal during night
 - (a) Due to temporary wilting (b) Permanent wilting
 - (c) Both (a) and (b)
- (d) None of the above
- Wilting of a plant results from excessive 41.

[CPMT 1994; AFMC 2001]

- (a) Respiration
- (b) Photosynthesis
- (c) Absorption
- (d) Transpiration
- 42. The plants face wilting due to use of excessive fertilizers **ICPMT 19981**
 - (a) Exosmosis
- (b) Endosmosis
- (c) Imbibition
- (d) None of these
- 43 How water rises from the rhizoids of Riccia to its assimilatory filaments? It is through
 - (a) Osmosis
- (b) Root pressure
- (c) Capillary
- (d) Transpiration pull
- Which of the following seeds will show more imbibitional pressure
 - (a) Til seeds
- (b) Gram seeds
- (c) Wheat seeds
- (d) Rice seeds
- Movement of molecules of gases, liquids and solids from a region of higher concentration to a region of lower concentration is termed as [KCET 1994; RPMT 1995]

Movement of particles of matter in the cell due to its own kinetic energy is called

- (a) Diffusion
- (b) Evaporation
- (c) Transpiration
- (d) Osmosis
- 46. During osmosis, water moves through a membrane

[MP PMT 1993; RPMT 1999]

FROM

TO

- (a) Low water potential
- High water potential
- (b) High solute concentration
- Low solute concentration
- (c) High osmotic potential
- Low osmotic potential
- (d) A hypotonic solution
- A hypertonic solution (more solute)
- (less solute)

- [WB JEE 2016]
- Incipient plasmolysis is
 - (a) Last stage of plasmolysis (b) Mid stage of plasmolysis
 - (c) Zero hour for inception of plasmolysis
 - (d) Initial stage of plasmolysis

O.P., T.P., I.P., D.P.D and Water potential

The osmotic parameter determining flow of water from one cell to another is

Or

The actual pressure with which water enters into cell is called [Pb. PMT 1999, 2004]

- (a) Osmotic pressure
- (b) Turgor pressure
- (c) Diffusion pressure deficit (d) Hydrostatic pressure

2. Addition of solute in the cell develops [AFMC 2008]

[BHU 2012]

DPD of a cells mainly depends upon (a) TP

(c) DP

- (b) OP (d) WP
- 3. 0.1M solution of a solute has a water potential of

[MP PMT 1995; BVP 2002]

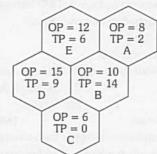

- (a) -2.3 bars
- (b) 0 bar
- (c) 22.4 bars
- (d) $+ 2.3 \, \text{bars}$
- 4. Root pressure develops due to

[AIPMT 2015]

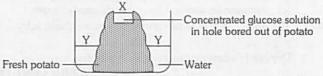

- (a) Low osmotic potential in soil
- (b) Passive absorption
- (c) Increase in transpiration
- (d) Active absorption
- 5. Which of the following statements are true / false
 - The positive hydrostatic pressure is called turgor pressure
 - Wall pressure exerts to prevent the increase of protoplasm size
 - Diffusion is more rapid in liquids than in gases
 - D. Diffusion of water through a semi-permeable membrane is called imbibition
 - Osmosis is movement of substances which takes place along a diffusion gradient

[Kerala PMT 2006]

- (a) A and B are true & C, D and E are false
- (b) A and C are true & B, D and E are false
- (c) A and D are true & B, C and E are false
- (d) A and E are true & B, C and D are false
- (e) C, D and E are true & A and B are false
- See the following diagram, when the TP of the cell B increases to 18. What changes would be occur with regard to water movement [NCERT]

- (a) No movement of water will occurred
- B actively absorb water from neighbor cell
- Water diffuses into B from outer cell
- Cells A, C, D and E absorb water from B
- 7. Observe the following experiment

After a few days, which of the following changes will have [NCERT]

- (a) A drop in level X and a rise in level Y
- (b) A rise in level X and a rise in level Y
- (c) A drop in level X and a drop in level Y
- (d) A rise in level X and a drop in level Y

UNIVERSAL BOOK DEPOT 1960

- 8. Cell A has osmotic potential of -18 bars and pressure potential of 8 bars, whereas, cell B has osmotic potential of -14 bars and pressure potential 2 bars. The direction of flow of water will be [AIIMS 2009]
 - (a) From cell B to cell A
- (b) From cell A to cell B
- (c) No flow of water
- (d) In both the directions
- In hypertonic solution a cell water potential
 - (a) Decreases
 - (b) Increases
 - (c) First increases then decreases
 - (d) No change
- In a fully turgid cells, the values of DPD, OP and TP will show the tendency

O

The cell is fully turgid when

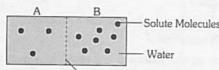

[J & K CET 2002; WB JEE 2010; Odisha JEE 2010]

- (a) DPD = 10 atm, OP = 15 atm, TP = 5 atm
- (b) DPD = 5 atm, OP = 12 atm, TP = 7 atm
- (c) DPD = 2 atm, OP = 7 atm, TP = 5 atm
- (d) DPD = 0 atm, OP = 15 atm, TP = 15 atm
- The osmotic potential and pressure potential of three cells (A, B, C) located in different parts of an actively transpiring plant are given below

Cell	Osmotic Potential (Mpa)	Pressure Potential (Mpa)
A.	-0.87	0.44
B.	-0.92	0.34
C.	-0.68	0.27

Identify these three cells as root hair, root cortical and leaf mesophyll cells respectively [EAMCET 2009]

- (a) A, B, C
- (b) A, C, B
- (c) C, A, B
- (d) B, C, A
- See the following figure and point out the statement which is not correct [NCERT]

- Semi permeable membrane

 (a) The direction and the rate of osmosis depend upon both the pressure gradient and conc. gradient
- (b) Presence of a SPM is a prerequisite for this process to occur
- (c) Movement of solute will take place from chamber A to B
- (d) Movement of solvent molecules will take place from chamber A to B
- 13. Select the correct statement for diagram below [NCERT]

- (a) Cell "A" will gain H₂O, Cell "B" will lose H₂O, Cell "C" neither gain nor loses H₂O
- (b) Cell "A" will gain H₂O, Cell "B" neither gain nor loses H₂O, Cell "C" will lose H₂O
- (c) Cell "A" neither gain nor loses H₂O, Cell "B" will gain H₂O, Cell "C" will loses H₂O
- (d) Cell "A" will lose H₂O, Cell "B" will gain H₂O, Cell "C" neither gain nor loses H₂O

- 14. Two cells A and B are contiguous. Cell A has osmotic pressure 10 atm, turgor pressure-7 atm and diffusion pressure deficit 3 atm. Cell B has osmotic pressure 8 atm, turgor pressure 3 atm and diffusion pressure deficit 5 atm. The result will be [CBSE PMT 2007]
 - (a) Movement of water from cell B to A
 - (b) No movement of water
 - (c) Equilibrium between the two
 - (d) Movement of water from cell A to B
- If water enters in a cell, the pressure exerted by its swollen protoplast is [AFMC 2004]

Or

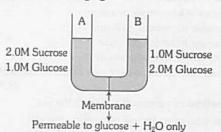

Turgidity of the cells is maintained by

- (a) Turgor pressure
- (b) DPD
- (c) Osmotic pressure
- (d) Imbibition
- 16. Addition of a solute to pure water causes [MP PMT 2001]
 - (a) Negative water potential
 - (b) More negative water potential
 - (c) Positive water potential
 - (d) More positive water potential
- 17. The ratio of osmotic pressure exerted by 1 M sucrose and 1 M NaCl solution will be [AIIMS 2010]
 - (a) 1

- (b) 2
- (c) 0.1
- (d) 0.5
- 18. When osmotic potential is either zero or negative and pressure potential is positive, then the water potential will be
 - (a) Negative
 - (b) Positive
 - (c) Sometimes negative and sometimes positive
 - (d) None of the above
- Which one of the following statements is wrong

[Kerala PMT 2007]

- (a) Water potential is the chemical potential of the water
- (b) Solute potential is always negative
- (c) Pressure potential is zero in a flaccid cell
- (d) Water potential equals solute potential in a fully turgid cell
- (e) Pressure potential is negative in a plasmolyzed cell
- **20.** What will be the effect of accumulation of K^+ ions in guard cells [GUJCET 2007]
 - (a) Water potential increases (b) Water potential decreases
 - (c) Loss of turgidity
- (d) Exosmosis
- 21. Observe the following figure

After the system reaches equilibrium, Which of the following

- (a) First the level of water is high in tube A and than water level is decreased
- (b) No change is observed

changes will have occurred

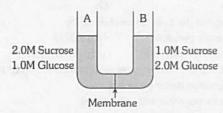

- (c) The water level is higher in side B than in side A
- (d) The water level is higher in side A than in side B

- 22. Under given suitable conditions, the DPD will be more than OP [BHU 1994]
 - (a) When OP is equal to TP
 - (b) When OP is less than TP
 - (c) When OP is greater than TP
 - (d) When TP is negative
- 23. Water is necessary for...

[MP PMT 2005]

- (a) Content of protoplasm
 - (b) Solvent
- (c) Reagent
- (d) All above
- 24. See the following diagram

Initially solution in side A, with respect to side B, is [NCERT]

- (a) Lower
- (b) Isotonic
- (c) Hypertonic
- (d) Hypotonic
- 25. Water potential can be obtained by
 - (a) OP + TP
- (b) OP = WP
- (c) P + n
- (d) OP DPD
- **26.** Solute potential of 0.a solution is always [DUMET 2010]
 - (a) = 0
- (b) > 0
- (c) < 0
- (d) Between 0-1
- **27.** Osmotic pressure of a solution is

[BVP 2004]

- (a) Greater than pure solvent
- (b) Less than pure solvent
- (c) Equal to pure solvent
- (d) Less than or greater than pure solvent
- Identify the correct relationship with reference to water potential of a plant cell. [KCET 2006]
 - (a) $\psi_w = \psi_m + \psi_s + \psi_p$
- (b) $\psi_w = \psi_m + (\psi_s \psi_p)$
- (c) $\psi_{w} = \psi_{m} (\psi_{s} + \psi_{n})$
- (d) $\psi_w = \psi_m \psi_s \psi_p d$
- 29. Water potential Ψ measured in bar or in
 - (a) lb/in²
- (b) mm of Hg
- (c) atm
- (d) All the above
- 30. Glucose is not stored in plant due to
- ICPMT 20101
- (a) Decrease in osmotic pressure
 - (b) Increase in osmotic pressure
 - (c) Increase in turgor pressure
 - (d) Decrease in turgor pressure
- When osmotic pressure becomes equal to the wall pressure, then [CPMT 1995]
 - (a) The flow of water will be inside the cell
 - (b) The flow of water will be outside the cell
 - (c) Both flow will occur inside as well as outside
 - (d) There will be no flow
- 32. What will be the direction of movement of water, when a solution A having water potential of 9 bars and another solution B of 4 bars is separated by a semipermeable membrane [AFMC 2003; KCET 2010]
 - (a) B to A
- (b) A to B
- (c) Both directions
- (d) None of these

- Turgor pressure becomes equal to the wall pressure when
 [Pb. PMT 1999]
 - (a) Water leaves the cell
 - (b) No exchange of water takes place
 - (c) Water enters the cell
 - (d) Solute goes from the cell into water
- When a plasmolysed cell is placed in a hypotonic solution then water will move inside the cell. Which force causes this

IRPMT 20021

- (a) DPD
- (b) OP
- (c) WP
- (d) None of these
- 35. When a cell is fully turgid, which of the following will be zero

[CBSE PMT 1997]

Or

The potential energy of water is referred to as

[J & K CET 2005]

- (a) Wall pressure
- (b) Osmotic pressure
- (c) Turgor pressure
- (d) Water potential
- When water moves through a semipermeable membrane, which of the following is created

[CPMT 1999; BHU 2000; CBSE PMT 2001]

- (a) OP
- (b) SP
- (c) TP

- (d) WP
- 37. Which statement is correct
- [DPMT 2004]
- (a) Osmotic pressure of solution is greater than pure solvent
- (b) Osmotic pressure of solution is lower than the pure water
- (c) Osmotic pressure of solution is equal
- (d) None of these
- **38.** Which of the following equations is correct in respect of osmotic phenomenon [WB JEE 2016]
 - (a) DPD = OP TP
- (b) DPD = OP + TP
- (c) $DPD = OP \times TP$
- (d) DPD = OP + TP

Absorption of water and Ascent of sap

- Transpiration and root pressure cause water to rise in plants by [AIPMT (Cancelled) 2015]
 - (a) Pulling and pushing it, respectively
 - (b) Pushing it upward
 - (c) Pushing and pulling it, respectively
 - (d) Pulling it upward
- Most widely accepted explanation for the ascent of sap in tree is [RPMT 1995; Pb. PMT 1999, 2000; BHU 2001; CBSE PMT 2001; J & K CET 2002; Kerala PMT 2009]
 - (a) Capillarity
 - (b) Roll of atmospheric pressure
 - (c) Pulsating action of living cells
 - (d) Transpiration cohesion theory of Dixon

UNIVERSAL BOOK DEPOT 1960

- 3. A column of water within xylem vessels of tall trees does not break under its weight because of [AIPMT 2015]
 - (a) Tensile strength of water
 - (b) Lignification of xylem vessels
 - (c) Positive root pressure
 - (d) Dissolved sugars in water
- 4. Which of the following is not true for active transport

[Odisha JEE 2012]

- (a) It is a chemical process
- (b) Energy is required for this process which is obtained in the form of ATP
- (c) It takes place through special organic molecules called carrier molecules
- (d) This process is not modified by enzymes
- 5. Upward movement of water in plants is called [BHU 2012]
 - (a) Sucking
- (b) Ascent of sap
- (c) Translocation
- (d) None of these
- 6. Water will be absorbed by root hairs when
 - (a) Concentration of salt in the soil is high
 - (b) Concentration of solutes in the cell sap is high
 - (c) Plant is rapidly respiring
 - (d) They are separated from soil by a permeable membrane
- 7. The factor or process which best explains the rise of water from roots(100 mts) to the top of tall tree is

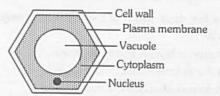

[UGET Manipal 1995, 96, 2005; KCET 2011; Odisha JEE 2011]

- (a) Break down of ATP
- (b) Root pressure
- (c) Capillary rise of water in xylem
- (d) Cohesion of water and transpiration pull
- 8. The path of water from soil upto secondary xylem is

[Kerala PMT 2008; KCET 2012]

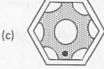

- (a) Soil → Root hair cell wall → Cortex → Endodermis → Pericycle → Protoxylem → Metaxylem
- (b) Metaxylem \rightarrow Protoxylem \rightarrow Cortex \rightarrow Soil \rightarrow Root hair
- (c) Cortex → Root hair → Endodermis → Pericycle → Protoxylem → Metaxylem
- (d) Pericycle → Soil → Root hair → Cortex → Endodermis
 → Protoxylem → Metaxylem
- 9. Physical force theory explains
 - (a) Non-living cells are not essential for ascent of sap
 - (b) Living cells are not essential for ascent of sap
 - (c) Ascent of sap may occur in both living and non-living cells
 - (d) Both (b) and (c)
- 10. The rupture and fractionation do not usualy occur in the water column in vessel/tracheids during the ascent of sap because of [CBSE PMT 2008]
 - (a) Weak gravitational pull (b) Transpiration pull
 - (c) Lignified thick walls
- (d) Cohesion and adhesion
- Which of the following would be in insignificant amount in xylem sap [KCET 2009]
 - (a) Sugar
- (b) Nitrates
- (c) Phosphates
- (d) Water

- 12. Bordered pits relating with water uptake located in
 - (a) Cortex
 - (b) Endodermis
 - (c) Vessel elements (Xylem duct)
 - (d) Tracheary elements
- Most of the water flow in the root takes place via the apoplast because [AMU (Med.) 2009]
 - (a) Cortical cells are loosely arranged
 - (b) Cortical cells are living cells
 - (c) Cortical cells are thin walled cells
 - (d) All of the above
- 14. The given diagram shows the appearance of plant cell immersed in a solution which is isotonic to the cell's sap

Which of the following diagrams shown below most accurately represents the appearance of this cell after immersion in a hypertonic solution [NCERT]

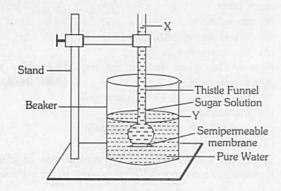

- Which of the following helps in the absorption of water and mineral salts [CPMT 1994; AIIMS 1999]
 - (a) Mycorrhiza
- (b) Anabaena
- (c) Nostoc
- (d) None of these
- 16. The given diagram indicates routes of transport of water and minerals from the soil through the root. Identify letters A, B, C and D [NCERT]

- (a) A Apoplastic, B Symplastic, C Cellulosic strip, D -Xylem vessels
- (b) A Symplastic, B Apoplastic, C Cellulosic strip, D phloem vessels
- (c) A Apoplastic, B Symplastic, C Casparian strip, D -Xylem vessels
- (d) A Symplastic, B Apoplastic, C Casparian strip, D Xylem vessels
- The movement of water from one cell of the cortex to the adjacent one in roots is due to [CBSE PMT 1995]
 - (a) Accumulation of inorganic salts in the cells
 - (b) Accumulation of organic compounds in the cells
 - (c) Chemical potential gradient
 - (d) Water potential gradient

18. Examine the experiment shown in the given figure

After a few days, which of the following changes will have occurred [NCERT]

- (a) A drop in level X and a rise in level Y
- (b) A rise in level X and a rise in level Y
- (c) A drop in level X and a drop in level Y
- (d) A rise in level X and a drop in level Y
- 19. Passage cells are thin walled cells found in [CBSE PMT 2007]
 - (a) Endodermis of roots facilitating rapid transport of water from cortex to pericycle
 - (b) Phloem elements that serve as entry points for substances for transport to other plant parts
 - (c) Testa of seeds to enable emergence of growing embryonic axis during seed germination
 - (d) Central region of style through which the pollen tube grows towards the ovary
- 20. Movement of H₂O through cell wall is called [DPMT 2007]
 - (a) Apoplast
- (b) Symplast
- (c) Tonoplast
- (d) None of these
- If two solutions have the same osmolarity, they are said to be [J & K CET 2005]
 - (a) Hypertonic
- (b) Hypotonic
- (c) Isotonic
- (d) None of these
- 22. Which of the following statements is/are true
 - A. The apoplastic movement of water occurs exclusively through the cell wall without crossing any membranes
 - Solutes present in a cell (or in any solution) increase the free energy of water or water potential
 - C. The symplastic movement occurs from cell to cell through the plasmodesmata
 - D. Membrane permeability depends on the membrane composition, as well as the chemical nature of the solute [Kerala PMT 2007]
 - (a) A and B only
- (b) B and D only
- (c) A, C and D only
- (d) A, B and D only
- (e) Conly
- 23. Which of the following statements is incorrect
 - (a) Water and salts are taken simultaneously by root hairs
 - (b) Plants absorb one thing at a time either water or inorganic salt
 - (c) Plants absorb excess quantity of water
 - (d) All of the above

24. Apoplastic movement of water in plants occurs through

[DUMET 2010]

- (a) Casparian strips
- (b) Plasma membrane
- (c) Intracellular spaces
- (d) Plasmodesmata
- **25.** When the concentration of the soil solutes is low, the absorption of water [KCET 2007]
 - (a) Remains normal
- (b) Is stopped
- (c) Is increased
- (d) Is decreased
- 26. Simultaneous movement of two molecules across a membrane in the same direction is know as

[NCERT; DUMET 2010]

- (a) Antiport
- (b) Symport
- (c) Uniport
- (d) Biport
- 27. Most accepted theory for ascent of sap is

[BHU 2006]

Or

Sap ascends in woody stems because of root pressure and

- (a) Capillarity theory
- (b) Root pressure theory
- (c) Pulsation theory
- (d) Transpiration pull
- 28. Root system in a plant is well developed [CBSE PMT 1990]
 - (a) Due to deficiency of auxin
 - (b) Due to deficiency of cytokinins
 - (c) Due to deficiency of minerals
 - (d) For increased absorption of water
- During absorption of water by roots, the water potential of cell sap is lower than that of [BHU 1994]
 - (a) Pure water and soil solution
 - (b) Neither pure water nor soil solution
 - (c) Pure water but higher than that of soil solution
 - (d) Soil solution but higher than that of pure water
- Storage capacity of the soil is the extent to which it can hold [RPMT 1995; Pune CET 1998; WB JEE 2016]

Oı

In soil, water available for plants is [CBSE PMT 1999; KCET 1999; BVP 2001; DUMET 2009]

- (a) Gravitational water
- (b) Capillary water
- (c) Hygroscopic water
- (d) All of the above
- 31. Active transport is characterized by

[RPMT 1997; AMU (Med.) 2010]

- (a) Requires special membrane proteins
- (b) Highly selective
- (c) Requires ATP energy
- (d) All of the above
- 32. The transport of water and salts takes place through

[CPMT 1996; MP PMT 1999, 2006]

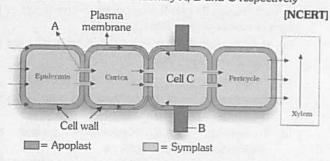

- (a) Phloem
- (b) Xylem
- (c) Sieve tubes
- (d) Sclerenchyma
- The direction of water in the leaflets of Cycas from midrib is
 [CPMT 1998]
 - ...
 - (a) Lateral
- (b) Downward
- (c) Upward
- (d) Downward and upward

UNIVERSAL BOOK DEPOT 1960

34. In plants, water supply is due to

[BHU 2006]

- (a) Osmosis
- (b) Imbibition
- (c) Guttation
- (d) Adhesion force
- The following diagram represent the pathway of water movement in the root. Identify A, B and C respectively

- (a) Plasmodesmata, Casparian strip, Endodermis
- (b) Tight junction, Casparian strip, Endodermis
- (c) Gap junction, Casparian strip, Endodermis
- (d) Desmosome, Casparian strip, Endodermis
- 36. The principle pathways by which water is translocated in angiosperms is [CBSE PMT 1990; BHU 2012]
 - (a) Xylem and phloem together
 - (b) Sieve tubes and members of phloem
 - (c) Sieve cells of phloem
 - (d) Xylem vessel system
- Passive absorption of water by the root system of the result of [KCET 2006, 10]
 - (a) Forces created in the cells of the root
 - (b) Increased respiratory activity in root cells
 - (c) Tension on the cell sap due to transpiration
 - (d) Osmotic force in the shoot system
- 38. Root hair absorb water from the soil on account of

[RPMT 2005]

- (a) Turgor pressure
- (b) Osmotic pressure
- (c) Suction pressure
- (d) Root pressure
- 39. The ability to rise in thin tubes and the Ability to resist a pulling force are respectively referred to as

[Kerala PMT 2012]

- (a) Tensile strength and capillarity
- (b) Adhesion and capillarity
- (c) Cohesion and adhesion
- (d) Cohesion and capillarity
- (e) Capillarity and tensile strength
- 40. Ascent of sap is due to which force [RPMT 1999]

Or

The most important force which pulls water up in tall trees is

- (a) Imbibition
- (b) Cellular force
- (c) Cohesive force
- (d) Atmospheric pressure
- 41. When water enters in roots due to diffusion, it is termed as

[AFMC 1999; BHU 2001]

- (a) Osmosis
- (b) Endocytosis
- (c) Active absorption
- (d) Passive absorption

42. Most water absorption in plants takes place through

[MP PMT 2001]

- (a) Root cap
- (b) Root apex
- (c) Root hair zone
- (d) Meristematic zone
- **43.** Na^+ , K^+ dependent ATPase activity helps in transport of

[DPMT 2004; Odisha JEE 2009]

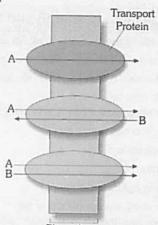

- (a) K+ inward, Na+ outward (b) K+ inward only
- (c) Na+ inward only
- (d) K+ outward, Na+ inward
- 44. The continuous excretion of watery substance from stump of a well watered pot plant after cutting off the shoot slightly above the base is due to [Pb. PMT 2004]

Or

Exudation of xylem is due to

[RPMT 1995]

- (a) Root pressure
- (b) Guttation
- (c) Transpiration
- (d) Imbibition
- 45. See the following diagram and identify the process occurring in I, II and III [NCERT]

Plasmalemma

	malik a	II	III
(a)	Uniport Symport Antiport	Antiport	Symport
(b)		port Co port	Antiport
(c)		Uniport	Symport
(d)	Co port	Symport	Antiport

Factors affecting absorption of water and Ascent of sap

- Which of the following factors affect the absorption of water by roots
 - (a) Soil temperature
- (b) Soil aeration
- (c) RH of the atmosphere
- (d) All the above
- 2. According to Sachs theory, the ascent of sap takes place
 - (a) In xylem ducts with the help of imbibition
 - (b) In the phloem with the help of imbibition
 - (c) In pith with the help of imbibition
 - (d) All of the above
- 3. The force of tension cohesion exceeds root pressure on a
 - (a) Rainy day
- (b) Foggy morning
- (c) Sunny day
- (d) Full moon night

- Many transplanted seedling may not survive because
 - (a) They do not like the new soil
 - (b) They do not get required mineral salts
 - (c) Most of the root hairs are lost during transplantation
 - (d) The leaves get damaged
- 5. At mid day hours, the xylem sap is in a state of
 - (a) Compression
- (b) Tension
- (c) Relaxation
- (d) Adhesion
- Water-logged condition will quickly occur in which type of soil [RPMT 1997]

Or

Holding capacity is highest in

[RPMT 1995]

- (a) Sand
- (b) Clay
- (c) Gravel
- (d) Loam
- When a potted plant is flooded with water, the magnitude of root pressure
 - (a) Increases
- (b) Decreases
- (c) Remains unchanged
- (d) Becomes negative

Transpiration (General) and Stomata

- 1. The chief role of transpiration in plants is to cause
 - (a) Loss of surplus water
- (b) Cooling of the plant
- (c) Rapid ascent of sap
- (d) Rapid rise of minerals
- 2. Guard cells help in

[Odisha JEE 2008; CBSE PMT 2009; AFMC 2012]

- (a) Protection against grazing
- (b) Transpiration
- (c) Guttation
- (d) Fighting against infection
- In woody trees, the exchange of gases between the outer atmosphere and the internal tissue of the stem takes place through [Kerala PMT 2010; NEET 2013]
 - (a) Aerenchyma
- (b) Stomata
- (c) Pneumatophores
- (d) Lenticels
- (e) Trichomes
- 4. The number of stomata and epidermal cells in 1 mm² leaf area of lower epidermis of the leaves of X, Y and Z plants are given below. Arrange the plants in decreasing order of their stomatal index.

Cell	Numbers of Stomata	Numbers of epidermal cells
Х	30	150
Y	60	240
Z	90	400

The correct answer is

[EAMCET 2009]

- (a) X, Y, Z
- (b) Y, Z, X
- (c) Z, Y, X
- (d) Y, X, Z
- **5.** Force generated by transpiration can create pressure sufficient to lift water even upto the height of

[AMU (Med.) 2012]

- (a) 130 feet
- (b) 130 metre
- (c) 230 feet
- (d) 230 metre

- 6. Position and frequency of stomata can be determined by
 - (a) Calculating the loss of water
 - (b) Cobalt chloride paper method
 - (c) Potometer
 - (d) Porometer
- In both transpiration and evaporation, water is lost in the form of vapour yet they differ, because
 - (a) Both transpiration and evaporation are similar but the rate of water loss differs
 - (b) Frequency of water loss is different in both of them
 - (c) Transpiration is a physical process and evaporation is a physiological process
 - (d) Transpiration is a physiological process and evaporation is a physical process
- Out of the following, which one is the most common type of transpiration
 - (a) Foliar
- (b) Stomatal
- (c) Lenticular
- (d) Cuticular
- 9. Which of the following is not the type of transpiration
 - (a) Stomatal transpiration
- (b) Cuticular transpiration
- (c) Lenticular transpiration
- (d) Endodermal transpiration

[MP PMT 1994]

- Maximum transpiration occurs in
 (a) Mesophytic plants
 (b)
 - (b) Hydrophytic plants
 - (c) Xerophytic plants
- (d) Algal cells
- Transpiration facilitates
- [KCET 2009]
- (a) Electrolyte balance
 - (b) Opening of stomata
 - (b) Opening of stornata
 - (c) Absorption of water by roots(d) Excretion of minerals
- 12. Transpiration is mainly a process of [Odisha JEE 2005]
 - (a) Osmotic pressure
- (b) Imbibition
- (c) Diffusion
- (d) Respiration
- Small (Tiny) particle is placed in the pore of stomata what will be happening [MP PMT 2005]
 - (a) It will fall on ground
 - (b) It will stick to lower epidermis
 - (c) It will be accommodate to mesophyll cell
 - (d) It will be accommodate in vascular tissues
- 14. Stomata of CAM plants

[CBSE PMT 2003; CPMT 2009; WB JEE 2016]

- (a) Never open
- (b) Are always open
- (c) Open during the day and close at night
- (d) Open during the night and close during the day
- 15. Transpiration ratio is the ratio of moles of H_2O transpired/moles of CO_2 fixed. This ratio is measure of

[AIEEE Pharmacy 2003]

- (a) The efficiency of guard cells on stomatal movement
- (b) Effectiveness of stomata is maximizing photosynthesis while minimizing water loss
- (c) Distinguishing a xerophyte from a glycophyte
- (d) Stomatal pore size of the leaves

			Transport in Plants 607
16.	are character of which plants	27.	Grafted flower is contained in saline water because
	[Pb. PMT 1999; RPMT 1999]		[CPMT 1996]
	(a) Heliophytes (b) Xerophytes (c) CAM Plants (d) All of these		(a) Suitable nutrient available to flower
17.	Which of the following is not a purpose of transpiration		(b) Flower become fresh in long duration due to less transpiration
	[Kerala PMT 2012] (a) Helps in absorption and transport in plants		(c) Flower become fresh in long duration due to regulated osmotic pressure of flower cell
	(b) Prevents loss of water		(d) Flower is protected by microbes
	(c) Maintains shape and structure of plants by keeping the	28.	Sunken stomata are found in leaves of [Odisha JEE 2005]
	cell turgid	20.	(a) Trifolium (b) Lemna
	(d) Supplies water for photosynthesis		(c) Nerium (d) Lilium
10	(e) Cools leaves surface	29.	Which process is favoured by transpiration
18.	The stomata remain closed during		(a) Photosynthesis (b) Conduction of water
	day time and open during night		(c) Stomatal opening (d) All the above
	[RPMT 1997; Odisha JEE 2012]	30.	
	(a) Photophilous (b) Succulents	00.	[CIMI 1990]
	(c) Sciphilous (d) Halophytes		마이 가지 않는 그 보고 있다고 있어요. 그런 하는 보고 있는데 보고 있는데 보고 있다면 보고 있다고 있다면 보고 있다면 보고 있다면 보고 있다. 그는데 보고 있는데 보고 있다면
19.	A small mesophytic twig with green leaves is dipped into	31.	
	water in a big beaker under sunlight. It demonstrates		The following percentage of water absorbed by herbaceous plants is lost in transpiration [JIPMER 2002]
	[MP PMT 1997]		(a) 80 (b) 60
	(a) Photosynthesis (b) Respiration (c) Transpiration (d) None of the above		(c) 90 (d) 40
20.	1-7-1-1-1-1-1-1-1-1-1-1-1-1-1-1-1-1-1-1	32.	Stomata in angiosperms does not open during
20.	Which of the following plant is able to show rolling of leaf during mid of the day	108	(a) Noon (b) Twilight
	(a) Nerium (b) Melia		(c) 11 O'clock (d) At midnight
	(c) Amophila (d) All the above	33.	Which of the following plants do not transpire
21.	Which of the following plants economises transpirational loss		(a) Algae
	of water		(b) Fungi
	(a) C_3 (b) C_4		(c) Submerged hydrophytes
	(c) Both equally (d) C_2		(d) All the above
22.	In barley type of plant, the stomata open	34.	Stomata open at night and close during day in
	(a) For few hours during day		[MP PMT 1999; RPMT 1999]
	(b) During night		Or
	(c) Throughout day and night		Sunken stomata are adaptations of which category of plants
	(d) Remain closed		[RPMT 1997]
23.	Stomatal frequency means		(a) Xerophytes (b) Gametophytes
	(a) No. of stomata per unit area of leaf surface		(c) Mesophytes (d) Hydrophytes
	(b) No. of epidermal cells per unit area of leaf surface	35.	Lenticular transpiration takes place in
	(c) No. of mesophyll cells in the per unit area of leaf		(a) Fruits (b) Woody stems
	(d) None of the above		
24.	Stomatal index I is equal to	26	
	(a) $\frac{S}{E-S}$ (b) $\frac{S}{E+S}$	36.	Which of the following wall of guard cells is thick
	E-S (b) $E+S$		(a) Outer (b) Inner
	(c) $\frac{E}{E+S}$ (d) $\frac{E+S}{F}$		(c) Side wall (d) All the three
	$E+S$ (d) \overline{E}	37.	The cells surrounding the stomatal pore are
25.	In Vallisneria, stomata are [RPMT 1995]		(a) Guard cells (b) Subsidiary cells
	(a) Present on upper epidermis of leaf		(c) Chromophil cells (d) None of the above
	(b) Present on lower epidermis of leaf	38.	Select the correct statement(s) pertaining to transpiration
	(c) Present on both the epidermis of leaf		process in plants [WB JEE 2016]
	(d) Not present		(a) It is a necessary evil for plants
26.	In most of the thin leaf mesophytes, the leaf stomata open		(b) Loss of water takes place through hydathodes in vapour
	during day and close during night. It comes under		form

form (b) Potato type

(a) Barley type

(c) Alfalfa type

(d) Bean type

(c) It may also occur through lenticels (d) The process is active during night in C_3 plants

Factors affecting transpiration

- 1. Due to low atmospheric pressure, the rate of transpiration will
 - (a) Decrease slowly
- (b) Decrease rapidly
- (c) Increase
- (d) Remain unaffected
- 2. Transpiration is minimised by the deposition of
 - (a) Cellulose
- (b) Pectin
- (c) Cutin
- (d) Mucilage
- Increase in temperature and velocity of wind cause an increase in transpiration initially but later it slows down, because
 - (a) Of closure of stomata
 - (b) Water is not made available
 - (c) The air around the plant becomes humid
 - (d) Of mechanical disturbance
- Which one of the following will reduce the rate of transpiration [Manipal MEE 1995;

MP PMT 2000; J & K CET 2002]

- (a) Increase in wind velocity
- (b) Rise in temperature
- (c) Increase in water uptake by plants
- (d) Decrease in light intensity
- Which of the following is produced during water stress and causes closure of stomata [BHU 2002; Odisha JEE 2009]
 - (a) Cytokinin
- (b) Auxin
- (c) GA3
- (d) ABA
- The conditions under which transpiration would be most rapid
 - (a) High humidity
 - (b) Excess of water in soil
 - (c) Low humidity, high temperature, guard cells are turgid (open) and moist soil
 - (d) Low velocity of wind
- The transpiration in plants will be lowest

[BHU 1994; KCET 2006]

- (a) When there is high humidity in the atmosphere
- (b) High wind velocity
- (c) There is excess of water in the cell
- (d) Environmental conditions are very dry
- 8. Which of the following is not a purpose of transpiration

[Kerala PMT 2010]

- (a) Supplies water for photosynthesis
- (b) Helps in translocation of sugars from source to sink
- (c) Maintains shape and structure of the plants
- (d) Cools leaf surfaces
- (e) Transports minerals from the soil to all parts of the plant
- 9. The rate of transpiration directly depends on
 - (a) Temperature
- (b) Negative turgor pressure
- (c) Diffusion pressure deficit (d) Vapour pressure gradient
- Which of the following may be used as an anti-transpirant in plant [MP PMT 1995;

KCET 2006; RPMT 2006; BHU 2008]

- (a) Phenyl mercuric acetate (b) Cobalt chloride
- (c) Mercury
- (d) Potassium

- 11. Transpiration increase with increase in [MP PMT 2005]
 - (a) Humidity
- (b) Temperature
- (c) Minerals
- (d) Soil moisture
- Under what conditions the rate of transpiration increases by [RPMT 1997]
 - (a) Increase of humidity
 - (b) Increase of atmospheric pressure
 - (c) Decrease of temperature
 - (d) Decrease of humidity
- 13. Which would do maximum harm to a tree [KCET 2007]
 - (a) Loss of half of its branches
 - (b) Loss of all of its leaves
 - (c) Loss of all its bark
 - (d) Loss of half of its leaves
- 14. Transpiration can be influenced by interfering with

[AFMC 1995]

- (a) Air temperature
- (b) Epidermis of leaf
- (c) Guard cell
- (d) Osmotic pressure
- 15. In the terrestrial habitat which of the following factors affect temperature and rainfall conditions
 - (a) Translocation
- (b) Transformation
- (c) Thermo-denaturation
- (d) Transpiration
- 16. Increase in CO₂ concentration around leaf results in

[CPMT 1995; CBSE PMT 2000]

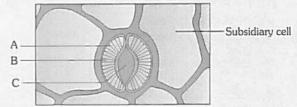

- (a) Rapid opening of stomata
- (b) Partial closing of stomata
- (c) Complete closure of stomata
- (d) There will be no effect on stomatal opening
- 17. Cobalt chloride method was first used by
 - (a) F. Darwin (1912)
- (b) Stahl (1894)
- (c) Curtis (1926)
- (d) Leibeg (1840)
- 18. Which one of the following is not an antitranspirant

[KCET 2011]

- (a) PMA
- (b) BAP
- (c) Silicon oil
- (d) Low viscosity

Mechanism of opening and Closure of stomata

 Observe the diagram of stomatal apparatus. In which of the following all the three parts labelled as A, B and C are correctly identified [NCERT]

- (a) A Guard cell, B Stomatal aperture, C Microfibril
- (b) A Stomatal aperture, B Guard cell, C Microfibril
- (c) A Microfibril, B Guard cell, C Stomatal aperture
- (d) A Microfibril, B Stomatal aperture, C Guard cell
- . Stomata on the surface of the leaf, open by [KCET 2012]
 - (a) Decreasing the solute concentration in the guard cells(b) Increasing the solute concentration in the guard cells
 - (c) Weakening of the cell walls of the guard cells to allow them to stretch
 - (d) Increasing the water potential in the guard cells

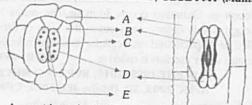

- 3 When stomata closes which of the following events does not [Odisha JEE 2008]
 - (a) Guard cell become flaccid
 - (b) Sugar is converted to starch
 - (c) O.P of the guard cell decreases
 - (d) Accumulation of O2 takes place
- Select the correct events leading to the opening of the stomata
 - Decline in guard cell solutes
 - (ii) Lowering of osmotic potential of guard cells
 - (iii) Rise in potassium levels in guard cells
 - (iv) Movement of water from neighbouring cells into guard
 - (v) Guard cells becoming flaccid

[Kerala PMT 2009]

- (a) (i) and (v) only (b) (ii), (iii) and (iv) only
- (c) (i), (iii) and (iv) only (d) (ii), (iv) and (v) only
- (e) (iii) and (v) only
- 5. Choose the correct combination of labelling of stomatal apparatus of dicot and monocot leaves

[NCERT; Kerala PMT 2006; CBSE PMT (Mains) 2010]

- (a) A = epidermal cells, B = subsidiary cells, C = chloroplast, D = guard cells, E = stomatal aperture
- (b) A = epidermal cells, B = guard cells, C = chloroplast, D = subsidiary cells, E = stomatal aperture
- (c) A = epidermal cells, B = subsidiary cells, C =chloroplast, D = stomatal aperture, E = guard cells
- (d) A = subsidiary cells, B = epidermal cells, C =chloroplast, D = stomatal aperture, E = guard cells
- (e) A = guard cells, B = epidermal cells, C = stomatalaperture, D = subsidiary cells, E = chloroplast
- The metal ion involved in the stomatal regulation is or Stomata will open, if there is accumulation of the following element in the guard cells

[JIPMER 1994; CPMT 2004; MP PMT 2005]

Opening and closing of stomata is controlled by

[BHU 2000; Haryana PMT 2005; Odisha JEE 2011]

- (a) Iron (Fe+)
- (b) Magnesium (Mg2+)
- (c) Zinc (Zn+)
- (d) Potassium (K+)
- 7. Conversion of starch to organic acid is essential for

[CBSE PMT 1992, 94]

- (a) Stomatal closure
- (b) Stomatal opening
- (c) Stomatal initiation
- (d) Stomatal growth
- Clarification of mechanism of opening and closing of guard cells is based on which of the following theory

[AIPMT (Cancelled) 2015]

- (a) Entry and exit of potassium in guard cell
- (b) Photosynthetic process taking place in guard cell
- (c) Starch-sugar conversion
- (d) Transpiration

9. Stomata open during day time because the guard cells

[CPMT 1993; MP PMT 1993]

- (a) Photosynthesize and produce osmotically active sugars or organic acids
- (b) Are thin-walled
- (c) Are bean shaped
- (d) Have to help in gaseous exchange
- 10. Stomatal opening or closing is due to

[CBSC PMT 2002; AMU (Med.) 2010; NEET 2017]

- (a) Change in the turgidity of guard cells
- (b) The inner wall of each guard cells is thick and elastic
- (c) Cellulose microfibrils of guard cells are oriented radially
- (d) All of the above
- According the Steward's starch hydrolysis theory, which one of the following is the principle reason for the opening of stomata during daytime
 - (a) Influx of K^+ ions into guard cells under the influence of ABA hormone
 - (b) Conversion of sugar into starch in guard cells
 - (c) Efflux of K^+ ions from guard cells under the influence of ABA hormone
 - (d) Photosynthetic utilization of CO₂ in guard cells
- 12. Basis of stomatal opening is

[MP PMT 2004]

A plant cell attains turgidity due to

[Kerala PMT 2004; WB JEE 2011]

Or

Turgor pressure of a plant cell increases due to

[WB JEE 2016]

- (a) Exosmosis
- (b) Endosmosis
- (c) Decrease in cell sap concentration
- (d) Plasmolysis of guard cells
- Which of the following theories is not related to the opening of stomata
 - (a) Sachs
- (b) K+ transport
- (c) Korper-Kappa theory
- (d) Levitt theory
- Na^+/K^+ pump in a cell is an example of

[AMU (Med.) 2010; AIIMS 2012]

- (a) Osmosis
- (b) Diffusion
- (c) Passive transport
- (d) Active transport
- Stomatal opening and closing is due to the permeability of the guard cell. This fact was revealed by
 - (a) Von Mohl
- (b) Linsbauer
- (c) Lloyd
- (d) Mansfield
- 16. Stomata open in the daytime due to

[Wardha 2005; KCET 2009]

- (a) Increase in water potential
- (b) Decrease in water potential
- (c) Decrease in pH
- (d) Light

BOOKD	DEPOT 1960			
17.	Which of the following statement is not true for stomatal	4.	From active hydathodes, the water comes out by	
	apparatus [NEET (Karnataka) 2013]		(a) Osmotic pressure	
	(a) Guard cells invariably posses chloroplasts and mitochondria		(b) Secreted by force developed within cells themselves	
	(b) Guard cells are always surrounded by subsidiary cells		(c) By root pressure	
	(c) Stomata are involved in gaseous exchange		(d) None of the above	
	(d) Inner walls of guard cells are thick	5.	Root pressure is due to [Odisha JEE 2011]	
18.	Stomatal mechanism operates in response to [CPMT 2005]		(a) Passive transport (b) Gravitation	
	(a) Temperature (b) Light		(c) Active transport (d) None of these	
	(c) Soil moisture (d) Atmospheric humidity	6.	Which one of the following is not related to guttation	
19.	Levitt explanation for stomatal action is due to		[KCET 2011]	
	(a) Increase in sugar content of guard cells		(a) Water is given out in the form of droplets	
	(b) Variations in pH value		(b) Water given out is impure	
	(c) Starch is converted into organic acids		(c) Water is given out early morning (d) Guttation is of universal occurrence	
	(d) Light causes opening and darkness closure	7.	The process of the escape of liquid from the tip of uninjured	
20.	The primary osmolite which causes an opening and closing		leaf is called [AIIMS 1998; MP PMT 2012]	
	of stomata is [RPMT 1999]		(a) Evaporation (b) Transpiration	
	(a) Sugars (b) Starch		(c) Guttation (d) Evapo-transpiration	
	(c) K-malate (d) Water	8.	Guttation is the process of elimination of water from plants	
21.	In guard cells when sugar is converted into starch, the	ar is converted into starch, the through or Guttation occurs from or The through which water comes out in the fo		
	stomatal pore [CBSE PMT 1992]		called or A specialized multicellular structure in leaves which	
	(a) Opens fully (b) Opens partially		excretes water droplets is called as [BHU 1995, 2004	
	(c) Closes completely (d) Remains unchanged		MP PMT 1995, 2010; BVP 2001; MHCET 2002; AFMC 2003, 10; Odisha JEE 2005; CPMT 2005	
22.	Which of the following theory gives the latest explanation for		(a) Stomata (b) Hydathodes	
	the closure of stomata [BHU 2004]		(c) Lenticels (d) Wounds	
	(a) ABA theory (b) Munch theory	9.	Guttation is found mostly in	
	(c) Starch glucose theory (d) Active K+ transport theory		(a) Herbaceous plant (b) Shrubs	
23.	Glycolate induces opening of stomata in [AIIMS 2010]		(c) Wood plants (d) None of these	
	(a) Presence of oxygen (b) Low CO ₂ concentration	10.		
	(c) High CO ₂ concentration (d) Absence of CO ₂		hydathodes. These hydathodes [KCET 2006]	
24.	In plants opening of stomata is regulated by [WB JEE 2016]		(a) Remain closed at night	
	(a) Red light (b) Blue light		(b) Remain closed during day (c) Remain always open	
	(c) Far-red light (d) Ultraviolet light		(d) Do not show any specificity in opening and closing	
	Guttation, Bleeding and Root pressure	11.		
Daily St			(a) Loosely arranged mass of parenchyma in hydathodes	
1.	Guttation is caused due to [KCET 2000, 07;		(b) Large intercellular spaces of hydathodes	
	AIIMS 2000; Uttranchal 2001; BHU 2001, 06;		(c) Xylem elements of hydathodes	
	Odisha JEE 2009; CBSE PMT (Mains) 2011]		(d) Phloem below the air chamber	
	(a) Imbibition (b) Osmosis	12.		
	(c) Positive root pressure (d) Transpiration		(a) Morning (b) Moon	
2.	Guttation usually occurs when the plant is put		(c) Evening (d) Morning 10 O'clock	
	(a) In more saturated atmosphere	13.		
	(b) In more humid soil		(a) Water stomata (b) Sunken stomata	
	(c) In dry condition		(c) Guard cells (d) Subsidiary cells	
	(d) In deserts	14.	Which one is not related to transpiration [MP PMT 1997	
3.	Which of the following is not a controlled process		(a) Regulation of plant body temperature	
	[BVP 2003]		(b) Absorption and distribution of mineral salts	
	(a) Transpiration (b) Guttation		(c) Circulation of water	
	(c) Both (a) and (b) (d) None of the above		(d) Blooding	

- 15. Which of the following is responsible for passive guttation
 - (a) Tension-cohesion of water molecules
 - (b) Activity of epithem tissue
 - (c) Osmotic activity of root hairs
 - (d) Secretion of fluid by mesophyll cells
- 16. Which of the following is more during the night
 - (a) Root pressure
- (b) Absorption
- (c) Evaporation
- (d) Transpiration

Scientists and Apparatus concerned

- 1. Ultrafiltration theory for permeability of cell membrane was put forth by
 - (a) Traube
- (b) Ruhland
- (c) Sachs
- (d) None of these
- 2. Pressure bomb technique was used by
 - (a) Scholander et al
- (b) Kramer et al
- (c) Dixon et al
- (d) None of the above
- 3. Who proposed the retension pressure theory for the permeability of the membrane
 - (a) Traube
- (b) Overton
- (c) Cocking
- (d) None of these
- Match the theories given in column I with the names of 4. scientists listed in column II. Choose the answer which gives the correct combination of the alphabets

LA NA	Column – I (Names of theories)	Column - II (Names of scientists				
A.	Relay pump theory	p.	Stocking			
B.	Transpiration cohesion theory	q.	Sir J.C. Bose			
C.	Mass flow	r.	Godlewski			
D.	Pulsation theory	s.	Dixon and Jolly			
	The state of the s	t.	Ernst Munch			

[BHU 1999; BVP 2003;

Kerala PMT 2004; KCET 2004; AIIMS 2013]

- (a) A = r; B = s; C = t; D = q
- (b) A = s; B = r; c = p; d = q
- (c) A = r; B = q; C = t; D = q
- (d) A = q; B = p; C = t; D = r
- Who explained the scotoactive opening of stomata
 - (a) Nishida
- (b) Palls
- (c) Ehrler
- (d) None of the above
- 6. Theory of starch-glucose interconversion was proposed by

Enzyme phosphorylase is first of all discovered in guard cells

- (a) Yin and Tung
- (b) Zelitch
- (c) Imamura
- (d) None of the above
- For photoactive opening of stomata, the proton transport concept was given by
 - (a) Levitt
- (b) Milborrow
- (c) Ziegler
- (d) None of the above

8. According to one vital force theory, ascent of sap is due to active pulsation of innermost layer of cortex. This theory was given by

Or

In plant 'transpiration pull' theory for ascent of sap was first proposed by [WB JEE 2016]

- (a) J. C. Bose
- (b) Dixon
- (c) Strasburger
- (d) Sacks
- The scientist, who proposed that production of glycolic acid 9. in guard cells is an important factor in stomatal opening, is
 - (a) Kumar
- (b) Steward
- (c) Zelitch
- (d) Lewitt
- 'Guttation' word is given by
 - (a) Fritz
- (b) Burgerstein
- (c) Noggle
- (d) Lewitt
- 11. Who studied the effect of light on translocation
 - (a) De Vries
- (b) Blackman
- (c) Williams
- (d) Hart
- 12 "There is no translocation at low temperature" has been invented by
 - (a) Swanson and Whitne
- (b) Fenson
- (c) Spanner
- (d) Munch
- Potometer works on the principle of 13. [CBSE PMT 2005]
 - (a) Amount of water absorbed equals the amount transpired
 - (b) Osmotic pressure
 - (c) Root pressure
 - (d) Potential difference between the tip of the tube and that of the plant
- 14. Who had said that "transpiration is a necessary evil"

- (a) Curtis
- (b) Steward
- (c) Andersen
- (d) J. C. Bose
- 15. Osmoscope is used for
 - (a) Measuring OP
- (b) Measuring TP
- (c) Measuring psi
- (d) Demonstration of osmosis
- Which of the following is used to determine the rate of transpiration in plants [CPMT 1994, 2009; AIIMS 2000; RPMT 2002; BHU 2003; MP PMT 2010, 12]
 - (a) Porometer
- (b) Potometer
- (c) Auxanometer
- (d) Tensiometer
- The term water potential was proposed by [CBSE PMT 2001] (a) Bose
- (b) Dixon
- (c) Godlewski
- (d) Slatyer and Taylor
- Potometer and clinostat are used to study [MHCET 2001]
 - (a) Photosynthesis and respiration
 - (b) Transpiration and growth
 - (c) Phototropism and geotropism
 - (d) Transpiration and geotropism
- Darwin's potometer determine
 - (a) Comparison of stomatal and cuticular transpiration
 - (b) Transpiration and absorption ratio
 - (c) Opening of stomata
 - (d) None of these

- 20. The best vital force theory was proposed by
 - (a) Godlewsky
- (b) Strasberger
- (c) Dixon
- (d) Esau
- 21. Who has used two bulbs of semipermeable membrane to explain pressure flow theory

Gradient pressure was given as a possible mechanism of translocation of food by

- (a) Munch
- (b) Jones
- (c) Spanner
- (d) Fenson
- 22. The shoot pressure is measured by
 - (a) G.M. Counter
 - (b) Luxmeter
 - (c) Pressure bomb technique
 - (d) Bomb calorimeter

Translocation of organic solutes

- 1. Who proposed that the upward and downward movement of materials take place
 - (a) Sacks
- (b) Boehm
- (c) Dixon
- (d) Curtis
- 2. The direction of the conduction of food through phloem is [MP PMT 1999]
 - (a) From below upwards
 - (b) From top to bottom
 - (c) From leaves to roots
 - (d) Phloem never conducts food
- In which form the food is translocated from endosperm to plumule of a fatty seed like castor
 - (a) Fatty acids
- (b) Fat
- (c) Glucose
- (d) Sucrose
- The figure indicates the ringing or girdling experiment. Bark having phloem is removed. This experiment proves that phloem is the path for translocation of food. In this experiment swollen part of stem has been shown. The possible cause of this swollen is [NCERT]

Bark + Phloem removed

- (a) Injured parts undergo turgidity
- (b) A repairing mechanism is taken place
- (c) Accumulation of water and mineral just above the ring
- (d) Accumulation of food material just above the ring (As downward movement of food is inhibited)
- 5. Phloem sap is mainly made of

[AMU (Med.) 2012]

- (a) Water and sucrose
- (b) Water and minerals
- (c) Oligosaccharides and hormones
- (d) None of these

- 6. The absorption of food in phloem is
 - (a) Basipetal
- (b) Acropetal
- (c) Both (a) and (b)
- (d) None of these
- 7. The food stored in the ripening fruit is derived from

[RPMT 1997]

- (a) Roots
- (b) Farthest leaves
- (c) Nearest leaves
- (d) Aerial stem
- 8. In cell transport the difference between permeable transport and bulk transport relates to
 - (a) Structure of molecules allowed to pass through
 - (b) Solvent system as well as structure of molecules are applicable
 - (c) Solvent system is applicable
 - (d) Molecular weight of atoms allowed to pass through
- 9. Sinks are related to
- [MP PMT 1997]
- (a) Transport of minerals
- (b) Stomata
- (c) Enzymes
- (d) Phytochrome
- Consider the following statements with reference to facilitated transport
 - A. Requires ATP energy
 - B. Transport Saturates
 - C. Highly selective
 - D. Requires special membrane properties
 - E. Uphill transport

Of the above statements

[Kerala PMT 2012]

- (a) A, B and C, are relevant but D and E are irrelevant
- (b) B, C and E, are relevant but A and D are irrelevant
- (c) C, D and E are relevant but A and B are irrelevant
- (d) A, D, and E are relevant but B and C are irrelevant
- (e) B, C and D are relevant but A and E are irrelevant
- Bidirectional translocation of minerals takes place in

[CBSE PMT 1997, 99]

By many evidences, it can be known that the downward movement of food takes place through [DPMT 2003]

- (a) Xylem
- (b) Phloem
- (c) Parenchyma
- (d) Cambium
- 12. Leaf photosynthates are transported to other parts of higher plants through [MP PMT 1994, 98]

Or

Food is transported to various parts of the plant through

[AIIMS 1998; BVP 2004]

- (a) Cambial cells
- (b) Pith cells
- (c) Xylem cells
- (d) Phloem cells
- Which is correct about transport or conduction of substances 13. [AFMC 1994]

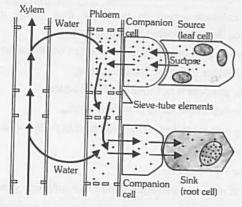

- (a) Organic food moves upwardly through xylem
- (b) Organic food moves up through phloem
- (c) Inorganic food moves upwardly and downwardly through xylem
- (d) Organic food moves upwardly and downwardly through phloem

UNIVERSAL BOOK DEPOT 1960

- During transport of sugar or amino acid through cell membrane [CBSE PMT 1994]
 - (a) Na^+ ions move against the direction of concentration gradient
 - (b) Na+ ions move in both directions irrespective of its concentration gradient
 - (c) No net Na+ ions movement
 - (d) Na+ ions move in the direction of its concentration gradient
- 15. By protoplasmic streaming theory, how sugar is translocated from one sieve tube to other
 - (a) Diffusion
- (b) Osmosis
- (c) Absorption
- (d) Active transport
- Supply ends in transport of solute are

[MP PMT 1997]

- (a) Green leaves and storage organs
- (b) Root and stem
- (c) Xylem and Phloem
- (d) Hormones and enzymes
- 17. The movement of materials through the vascular tissue of plants is called [BHU 2002]
 - (a) Transpiration
- (b) Translocation
- (c) Transcription
- (d) Transduction
- According to all Munch's pressure-flow hypothesis, which of the following given conditions would increase the rate of translocation [NCERT]

- (a) A decrease in the photosynthesis
- (b) An increase in the sucrose production at the source
- (c) A decrease in phloem unloading at the sink
- (d) An increase in the humidity in the outside air
- Active transport of solute in plants refers to flow of solutes against a concentration gradient and therefore requires input of energy. This energy is derived

[BHU 1995; AIEEE Pharmacy 2004]

- (a) Always from hydrolysis of ATP
- (b) Not only from ATP hydrolysis but also from the collapse of a proton motive force
- (c) Partly form the input from ATP hydrolysis and partly from the collapse of a proton motive force
- (d) From the different sources depending on the solutes

When a plant is girdled or In a ring girdled plant

[AIPMT (Cancelled) 2015]

- (a) The root dies first
- (b) The shoot dies first
- (c) The root and shoot die at the same time
- (d) Neither the root nor the shoot will die
- The carbohydrates synthesized in the leaves are transported through sieve tubes most commonly in the form of

[CBSE PMT 1992]

Or

Translocation of sugar in flowering plants occurs in the form of [NCERT; CPMT 1998; AMU (Med.) 2006; MP PMT 2006]

- (a) Glucose
- (b) Triose sugar
- (c) Sucrose
- (d) Soluble starch
- 22. Starch is insoluble in water yet it is accumulated in large quantities in potato because [CPMT 2004]
 - (a) It is synthesized in potato tuber itself
 - (b) It is translocated from the leaves to the potato tuber in the form of sugar
 - (c) Soil micro-organism deposit starch in tuber
 - (d) It is useful consumption
- 23. According to Munch theory, the cause of flow of soluble substances is
 - (a) Protoplasmic flow
 - (b) Mass flow due to reduction in turgor pressure
 - (c) Diffusion
 - (d) None of these
- The translocation of organic solutes in sieve tube members is supported by [CBSE PMT 2006]
 - (a) Mass flow involving a carrier and ATP
 - (b) Cytoplasmic streaming
 - (c) Root pressure and transpiration pull
 - (d) P-proteins
- 25. Who proposed blood like translocation of solutes
 - (a) Spanner
- (b) Munch
- (c) Williams
- (d) Jones
- 26. Organic substances such as sugars are translocated in phloem can be demonstrated by
 - (a) Defoliation
- (b) Ringing the stem
- (c) Grafting
- (d) Root pressure
- 27. Vein loading is the active transport of sugars from

[KCET 2012]

- (a) Mesophyll cells to vessels
- (b) Vessels to mesophyll cells
- (c) Mesophyll cells to sieve tubes
- (d) Sieve tubes to mesophyll cells
- 28. Munch hypothesis is based on

[KCET 2007]

- (a) Translocation of food due to TP gradient and imbibition force
- (b) Translocation of food due to Turgor Pressure (TP) gradient
- (c) Translocation of food due to imbibition force
- (d) None of the above

- Which one of the following elements is necessary for the translocation of sugars in plants
 - (a) Iron

(b) Manganese

- (c) Molybdenum
- (d) Boron
- **30.** Which of the following is the main point in disfavour of Munch theory
 - (a) Translocation is a pure physiological process
 - (b) Translocation is a pure physical process
 - (c) Explaination of sugar transport is not given
 - (d) None of these
- **31.** Which of the following criteria **does not** pertain to facillitated transport [NEET 2013]
 - (a) Uphill transport
 - (b) Requirement of special membrane proteins
 - (c) High selectivity
 - (d) Transport saturation

NCERT Exemplar Questions

- Which of the following statements does not apply to reverse osmosis [NCERT]
 - (a) It is used for water purification
 - (b) In this technique, pressure greater than osmotic pressure is applied to the system
 - (c) It is a passive process
 - (d) It is an active process
- 2. Which one of the following will not directly affect transpiration [NCERT]
 - (a) Temperature
 - (b) Light
 - (c) Wind speed
 - (d) Chlorophyll content of leaves
- 3. The lower surface of leaf will have more number of stomata in a [NCERT]
 - (a) Dorsiventral leaf
- (b) Isobilateral leaf
- (c) Both a and b
- (d) None of the above
- The process of guttation takes place
- ace [NCERT]
- (a) When the root pressure is high and the rate of transpiration is low
 - (b) When the root pressure is low and the rate of transpiration is high
 - (c) When the root pressure equals the rate of transpiration
 - (d) When the root pressure as well as rate of transpiration are high
- 5. Which of the following is an example of imbibition [NCERT]
 - (a) Uptake of water by root hair
 - (b) Exchange of gases in stomata
 - (c) Swelling of seed when put in soil
 - (d) Opening of stomata
- Water potential of pure water at standard temperature is equal to [NCERT; NEET 2017]
 - (a) 10

(b) 20

(c) Zero

(d) None of the above

- 7. Match the followings and choose the correct option
 - A. Leaves
- . Anti-transpirant
- B. Seed
- ii. Transpiration
- C. Roots
- iii. Negative osmotic potential
- D. Aspirin
- v. Imbibition
- E. Plasmolyzed cell
- v. Absorption
- Options
- •

D-ii

- (a) A-iii, B-iv, C-i,
- (b) A-i, B-ii, C-iii, D-iv
- (c) A-iii, B-ii, C-iv, D-i
- (d) A-iii, B-ii, C-i, D-iv
- 8. Mark the mismatched pair
- [NCERT]
 Store protein granule

[NCERT]

- (a) Amyloplast
- i. Store protein gran
- (b) Elaioplast
- ii. Store oils or fats
- (c) Chloroplasts
- iii. Contain chlorophyll pigments
- (d) Chromoplasts
- iv. Contain coloured
 Pigments other than chlorophyll
- (e) Leucoplast
- v. Contains colourless
 - pigments

Critical Thinking

Objective Questions

- Purple cabbage leaves do not loose their colour in cold water but do so in boiling water because
 - (a) Plasma membrane get inactivated in boiling water
 - (b) Hot water can enter the cells readily
 - (c) The pigment is not soluble in cold water
 - (d) The cell wall is killed in boiling water
- 2. Primary and secondary active transport both [WB JEE 2008]
 - (a) Generate ATP
 - (b) Use ATP directly
 - (c) Can move solutes against their concentration gradient
 - (d) Include the passive movement of glucose molecule
- When a plant cell is placed in a solution which is hypotonic to the cell sap, which of the following conditions will not apply
 - (a) The water potential of the cell sap will rise
 - (b) The suction pressure of the cell sap will fail
 - (c) The cell will become turgid
 - (d) The wall pressure of the cell will fail
- 0.5 M sucrose solution develops a pressure of 15 bars in an osmometer. Which of the following statement is wrong for such a solution
 - (a) That its osmotic potential is 15 bars
 - (b) That its water potential is 15 bars
 - (c) That its pressure potential is 15 bars
 - (d) That its osmotic pressure is + 15 bars

5. A cell when dipped in 0.5 M sucrose solution has no effect but when the same cell will be dipped in 0.5 M NaCl solution the cell will [AFMC 2005]

Increase in size

(b) Decrease in size

Will be turgid

- (d) Will get plasmolysed
- In which of the following plants would metabolism be 6. hindered if the leaves are coated with wax on their upper

(a) Hydrilla

(b) Lotus

(c) Pistia

- (d) Vallisneria
- 7. An osmometer is filled with 0.5 M solution of NaCl in water. In which of the following solutions it must be immersed in order to make it shrink [KCET 2012]

(a) 0.5 M solution

(b) 0.05 M solution

(c) Distilled water

(d) 0.75 M solution

- 8. In water-logged soil, plants do not grow properly because [CPMT 1995]
 - (a) The soil is physiologically dry
 - (b) The soil is physiologically wet
 - (c) Due to excessive water
 - (d) Due to shortage of water
- Turgidity in guard cells is controlled by [MP PMT 2001, 06]
 - (a) Chloride
 - (b) Malic acid
 - (c) Potassium
 - (d) Potassium, chloride and malic acid
- 10. Root pressure is maximum when

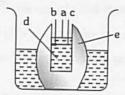

[JIPMER 2002; Odisha JEE 2008]

- (a) Transpiration is high and absorption is very low
- (b) Transpiration is very low and absorption is high
- (c) Transpiration is very high and absorption is also high
- Transpiration and absorption both are slow
- In which of the following the rate of transpiration is high 11.

[MP PMT 2001]

(a) CAM plants

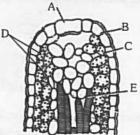

- (b) C₃ plants
- (c) C3 and C4 plants (d) C₄ plants A thin film of water, held by the soil particles under the influence of internal attractive force, is called which of the following water [Pb. PMT 2000; MHCET 2003]
 - (a) Capillary
- (b) Combined
- (c) Hygroscopic
- (d) Gravitational
- A sufficient atmospheric pressure required to push the water upto the top of tall plants must be [BVP 2003]
 - (a) 2 atm
- (b) 6 atm
- (c) 20 atm
- (d) All of the above
- Choose the correct combination of labelling of the potato osmoscope experiment [Kerala PMT 2004]

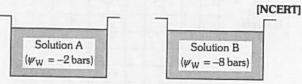

- (a) a-final level, b-dotpin, c-initial level, d-sugar solution, e-potato tuber
- (b) a-initial level, b-dotpin, c-final level, d-water, e-potato
- (c) a-final level, b-dotpin, c-initial level, d-water, e-potato
- (d) a-final level, b-dotpin, c-final level, d-water, e-container
- a-initial level, b-dotpin, c-final level, d-coconut oil, e-potato tuber

15. Choose the correct combination of labelling of hydathode

[Kerala PMT 2004]

- (a) A-guard cells, B-epithem, C-mesophyll, D-epidermis,
- (b) A-guard cells, B-epidermis, C-mesophyll, D-epithem, E-vasculature
- (c) A-ostiole, B-epidermis, C-mesophyll, D-epithem, E-vasculature
- (d) A-water pore, B-hypodermis, C-mesophyll, D-epithem,
- 16. The removal of a ring of bark from trunk of a tree eventually kills it, since [BHU 1994]
 - (a) Mineral salts cannot go up
 - (b) Water cannot go up
 - (c) Food does not travel down and roots are starved
 - (d) The exposed part becomes infected with fungi
- Where does transpiration cohesion pull theory works 17.
 - (a) Active absorption
 - (b) Inactive absorption
 - (c) Active and inactive absorption
 - (d) None of these
- The speed of water absorption will be greater if 18.
 - (a) The difference between osmotic pressure of soil water and that of xylem vessels is always less
 - (b) The difference between osmotic pressure of soil water and that of xylem vessels is always more
 - (c) The osmotic pressure of soil water is always more than that of xylem vessels
 - (d) The osmotic pressure of soil water is always less than that of xylem vessels
- During absorption of H_2O by roots, the H_2O potential of cell sap is lower than that of [DPMT 2004]
 - (a) Solution outside
- (b) That of pure H2O
- One
- (d) None of these
- See the following figure and select the correct option

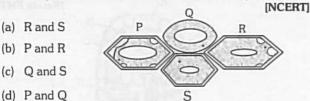

- (a) Water potential has nothing to do with K.E. of water in a solution
- (b) K.E. of water in A solution = K.E. of H₂O in B solution
- (c) K.E. of water in B solution > K.E. of water in A solution
- (d) Kinetic energy (K.E.) of H2O in A solution> K.E. of water in B solution

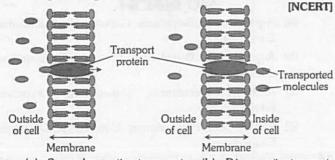

UNIVERSAL BOOK DEPOT 1960

616 Transport in Plants

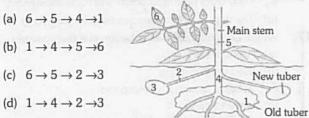

21. See the following diagram of four plant cells. Select the correct option in which cells would not exit wall pressure

22. The given diagram shows the transportation of materials by

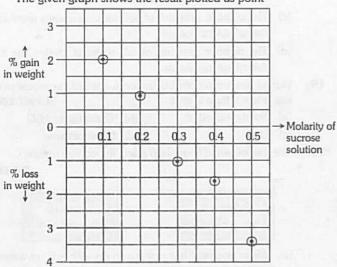

- (a) Secondary active transport
- (b) Primary active transport
- (c) Facilitated diffusion
- (d) Simple diffusion
- 23. The given diagram illustrates a Potato plant forming new tubers. Which route would be taken by most of the food at this time [NCERT]

24. The experiment given below shows groups of potato disc were weighed and then each group was immersed in one of a series of sucrose solutions. After two hours each group was reweighed and its percentage gain or loss in weight was calculated

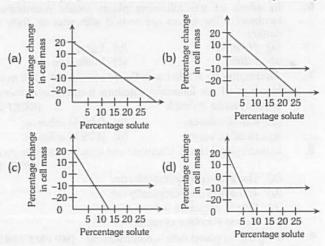

The given graph shows the result plotted as point

From these results it can be concluded that the water concentration of potato cell sap is approximately equivalent to that of a sucrose solution of molarity [NCERT]

- (a) 0.50
- (b) 0.35
- (c) 0.25
- (d) 0.10

25. The effect of solute concentration on the mass of tissue cells is studied. It is observed from the collected data that the tissue cells were isotonic to 10 % solute concentration. Which of the following graph represents that the cells are isotonic to 10 % solute concentration [NCERT]

- **26.** Which of the following is not correct in mass flow hypothesis [KCET 2015]
 - (a) As hydrostatic pressure in the phloem sieve tube increases pressure flow stops and sap is accumulated in phloem
 - (b) The sugar is moved bidirectionally
 - (c) The sugar which is transported is sucrose
 - (d) Loading of the phloem sets up a water potential radient that facilitates the mass movement in the phloem
- 27. Water vapour comes out from the plant leaf through the stomatal opening. Through the same stomatal opening carbon dioxide diffuses into the plant during photosynthesis. Reason out the above statements using one of following options [NEET (Phase-I) 2016]
 - (a) Both processes cannot happen simultaneously
 - (b) Both processes can happen together because the diffusion coefficient of water and CO₂ is different
 - (c) The above processes happen only during night time
 - (d) One process occurs during day time and the other at night
- Specialised epidermal cells surrounding the guard cells are called [NEET (Phase-I) 2016]
 - (a) Complementary cells
 - (b) Subsidiary cells
 - (c) Bulliform cells
 - (d) Lenticels

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- 1. Assertion : Xylem is principal water conducting tissue.
 - Reason : It has been recognised by girdling or ringing experiment. [AIIMS 1995]
- 2. Assertion : Water and mineral uptake by root hairs from the soil occurs through apoplast until it reaches endodermis.
 - Reason : Casparian strips in endodermis are suberized. [AIIMS 2003]
- 3. Assertion : Long distance flow of photoassimilates in plants occurs through sieve tubes.
 - Reason : Mature sieve tubes have parietal cytoplasm and perforated sieve plates. [AIIMS 2003]
- 4. Assertion : Arid areas are not suitable for crops.
 - Reason : Antitranspirants are used for planting crops in arid regions.
- 5. Assertion : Oil will form a film on the top of the water affecting the amount of light entering the
 - Reason : Oil is a polar molecule, and forms hydrogen bonds. [AIIMS 2009]
- **6.** Assertion : Film forming chemical should not be used for checking transpiration.
- Reason : Film forming chemicals interrupt photosynthesis and respiration.
- 7. Assertion : Stomata are "turgor operated valves"
- Reason : Stomata show reversible turgor changes.
- 8. Assertion : Wilting occurs due to loss in turgidity.

 Reason : Turgor pressure checks the excessive entry
 - of water into cells.
- Assertion : Temporary and permanent wilting result in plant death.
 - Reason : Plant parts become flaccid in wilting condition.
- **10.** Assertion : Seeds and spores do not lose the viability in unfavourable periods.
 - Reason : Seeds and spores have high osmotic pressure.
- 11. Assertion : To counteract the increase in turgour pressure in plant cells, the cell wall produces an equal and opposite pressure,
 - Reason : When plant cells undergo endosmosis, they swell but do not burst. [KCET 2010]

- 12. Assertion : Plasmolysis will be severe if the process is in the order, limiting → incipient → evident.
 - Reason : Plasmolysis is exosmosis.
- Assertion : Water absorption is reduced by lowering O₂ tension.
 - Reason : The accumulation of CO₂ reduces water absorption.
- 14. Assertion : Upward movement of water is called ascent of sap.
 - Reason : Upward movement of water occurs through xylem and phloem.
- 15. Assertion : Plants absorb water mostly by roots.
 - Reason : Root cap region participates actively in water absorption.
- **16.** Assertion : Field capacity is maximum in loam soil.
- Reason : In water logging condition, the soil has maximum field capacity.
- 17. Assertion : Only vertical movement of water is possible through xylem and tracheids.
- Reason : The xylem ray parenchyma is responsible for the lateral transport of water.
- **18.** Assertion : Light is very important factor in transpiration.
 - Reason : It induces stomatal opening and darkness closing. Therefore, transpiration increases
- in light decreases in dark. [AIIMS 1999]

 19. Assertion: Waxy and cutin coating on plant parts
 - reduce the transpiration.
 - Reason : These adaptation are found in xerophytes.

 [AIIMS 1999]
- 20. Assertion: Water in liquid form reaches to plant surfaces in transpiration process.
 - Reason : At plant surface, water changes from liquid to vapour phase.

Answers and Solutions

General

- (a) The guard cells of monocots (family Gramineae) are dumbel shaped or elliptical, e.g., Sugarcane.
- (c) Because loss of water takes place through leaves by transpiration.
- (b) On removing the ring of bark, phloem and cambium are removed from stem.
- (b) Loam are sufficiently aerated and have good water holding capacity. Therefore, they are very good for water absorption and growth.
- (b) Energy is usually provided by ATP or by concentration gradient of ions.
- (b) Alluvial soil allows percolating the water slowly from it, hence alluvial soil is good soil.
- 10. (a) Because the water molecules have a great mutual attraction with each other or in other words they have tremendous cohesive power which is sometimes as much as 350 atmospheres.
- (a) Walls of tracheids and vessels of xylem are made up of lignin and cellulose and have strong affinity for water (adhesion).
- (a) ATP releases small amount of energy required for building new chemical bonds or chemical reactions in cell.
- 14. (a) Active absorption takes place by the activity of root itself, particularly root hairs. A root hair cell functions as an osmotic system. Water is absorbed by the root hair due to osmotic differences between soil water and cell sap.
- 16. (d) Root cap has no function in water absorption because it has no root hair and it is mainly for protection of root tip against any injury.
- 18. (c) In monocot like sugarcane, maize, etc. due to absence of cambium secondary growth is not found. So removal of bark (phloem) is not possible so that ringing experiment is not possible.
- (c) The amount of water present in soil against gravitational force is called as field capacity.

Membranes, osmosis, diffusion, imbibition, plasmolysis and Wilting

- 3. (c) This type of membrane allow selective passage of solutes along with solvent through them. Many biological membranes such as cell membranes, tonoplast and the membranes surrounding the subcellular organelles are selectively permeable.
- 5. (d) In formalin preserved Spirogyra filament, osmosis does not take place.
- (b) Osmosis is a special type of diffusion or Osmosis through semipermeable membrane.
- 7. (b) Osmosis is a special type of diffusion of a liquid, when solvent moves through a semipermeable membrane from a place of higher diffusion pressure to a place of lower diffusion pressure.
- (d) Because in imbibition process, the volume of seed is increased.
- 13. (b) Plasmolysis is the shrinkage of protoplast of a cell from its cell wall under the influence of a hypertonic solution. The hypertonic solution causes exosmosis or withdrawl of water from the cell. A solution whose osmotic concentration is more than that of another solution or cell sap is called hypertonic solution.
- 14. (a) In osmosis, movement of water takes place from hypotonic solution to hypertonic solution through semipermeable membrane.
- 16. (d) Breaking of the seed coat in germinating seeds is due to greater imbibitional swelling of the seed kernel (starch and protein) as compared to seed coverings. Seedling is able to come out of soil due to development of imbibition pressure.
- 17. (b) Thistle funnel whose mouth is tied with parchment paper is the physiological experiment of osmosis. Parchment paper is a semipermeable membrane which allows all solvents but no solute to pass through them.
- (a) Plasmalemma allows selective passage of solutes along with solvent, through them.
- 19. (b) Plasma membrane shows selectively permeable membrane hence it controls passage of water and some solutes in and out of the cell.
- **20.** (c) Peel of *Tradescantia* leaf is generaly used for the demonstration of plasmolysis in laboratory.
- 22. (a) When a cell is placed in distilled water, water start moving into the cell by the process of endosmosis, and cell become turgid.
- 23. (a) If a cell is placed in isotonic solution, there is no net changes of water between the cell and the solution.
- 24. (d) Proteins are the strongest imbibants of water, starch less strong, cellulose being the weakest. That is why proteinaceous pea seeds swell more than the starchy wheat seeds.

- 25. (a) At noon the rate of transpiration is maximum. The rate of water absorption is less due to shrinkage of roots and depletion of water around the root hairs.
- 26. (b) Because of exosmosis.
- 27. (d) The water is first imbibed by walls of root hairs and then absorbed and helps in rupturing of seed coat (made up of cellulose). Materials capable of imbibition such as proteins and cellulose in living beings cause seeds to swell when they are placed in water.
- (d) Removal of large molecule from cell is also known as exocytosis.
- 29. (b) Due to exosmosis, the protoplasm shrinks and leaves the cell wall and thus cell becomes flaccid, which is called plasmolysed cell and this phenomenon is called plasmolysis. Thus exosmosis leads to plasmolysis.
- 30. (c) Consumption and production of solvent does not take place in osmosis. It is the just migration of solvent from the hypotonic to hypertonic solution hence volume of solvent remains same.
- 31. (d) Selectively permeable membrane such as membrane of root hairs and tonoplast membrane of vacuole allows certain substances more readily then semipermeable membranes.
- **32.** (c) In case exosmosis continues, the protoplasm shrinks from the cell wall. The phenomenon is called plasmolysis (flaccid in appearance). Plant part or in the cells due to scarcity of water are termed as wilting.
- 33. (d) If the plasmolysed cell (flaccid cell) is placed in hypotonic solution then endosmosis occurs, which makes the cell again turgid and this is known as deplasmolysis.
- 34. (a) Due to exosmosis.
- 35. (a) Because water contents of potato comes out from the potato tuber or due to exosmosis.
- (a) Due to adsorption of water molecules into wooden furniture it get swelled.
- 38. (d) Due to exosmosis (plasmolysis), the protoplasm shrinks and leaves the cell wall and thus cell becomes flaccid which is called plasmolysed cell.
- 39. (a) Xylem is responsible for transport of water. If xylem is blocked, plant will undergo wilting due to the lack of proper transport of water.
- 40. (a) It is the temporary drooping down of leaves and young shoots due to loss of turgidity during noon. At this time the rate of transpiration is maximum. Temporary wilting is corrected only after the rate of transpiration decreases in the afternoon accompanied by replenishment of water around the root hairs.
- 41. (d) Rapid transpiration causes mid-day leaf water deficit (temporary wilting). If such condition continues for sometime, permanent water deficit permanent wilting may develop, which causes injury to plants.

- 42. (a) Because of excessive fertilizers concentration are increased and water comes out of the plant cells due to exosmosis.
- 43. (a) Because cell wall of rhizoids and assimilatory filament cells work as semipermeable membrane.
- 44. (b) Imbibition pressure can be defined as the maximum pressure that an imbibant will develop when it is completely soaked in pure water. In Gram seeds (proteins) also have high imbibition capacity.
- **45.** (a) Diffusion may be defined as, "movement of particles of a matter due to their own kinetic energy".
- 46. (d) It is the migration of solvent through a semipermeable membrane to keep the concentration equal.
- 47. (b) Plasmolysis takes place in 3 stages
 - (A) Limiting plasmolysis (1st stage)
 - (B) Incipient plasmolysis (Mid stage)
 - (C) Evident plasmolysis (Last stage)

O.P., T.P., I.P., D.P.D and Water Potential

- (c) The amount by which D.P. of solution is lower than that
 of its pure solvent, is called diffusion pressure deficit
 (D.P.D.).
- (a) 1 M solution of a solute at normal temperature and pressure has water potential – 23 bars, hence 0.1 M solution will have water potential – 2.3 bars.
- (a) Water potential of cell protoplasm is equal but opposite in sign to D.P.D. Water potential of pure water is zero and addition of solute in it, decreases it.
- (d) In a fully turgid cell, O.P. is equal to T.P. and thus D.P.D. is zero.
- 11. (c) Water potentials of the given cells are $\psi = \psi_S + \psi_R$

1 007 044 04

A = -0.87 + 0.44 = -0.43

B = -0.92 + 0.34 = -0.58C = -0.68 + 0.27 = -0.41

As water moves from greater water potential to less, root hair, root cortical and leaf mesophyll cells are C, A, B respectively.

- 15. (a) The hydrostatic pressure developed inside the cell on the cell wall due to endosmosis is called turgor pressure. It is responsible for growth of young cells.
- 16. (a) The pure water, at atmospheric pressure, has zero water potential. The addition of any solute particles reduces the free energy of water. Thus the water potential will be negative.
- 18. (a) Osmotic potential or solute potential (ψ_s) are always in negative values and pressure potential (ψ_p) is usually positive. Water potential of a solution is always less than zero or has negative value.
- 20. (b) The opening and closing of stomata depends on the concentration of solutes in the guard cells (the main component of the solute concentration in guard cells is K⁺). When the concentration of solutes, K⁺ ion guard cells increases, their osmotic pressure increases. In other words, their water potential decreases. As a result of this, they absorb water from their surrounding epidermal cells, their turgidity increases.

UNIVERSAL BOOK DEPOT 1960

- 22. (d) When T.P. is negative, DPD will be more than OP. D.P.D. of a cell mainly depends upon OP.
- **25.** (c) $\psi = P + \pi$; where $\psi =$ Water potential, P = Osmotic pressure, $\pi =$ Osmotic potential.
- 29. (d) A bar is a pressure unit which equals 14.5 lb/in², 750 mm Hg or 0.987 atm.
- 31. (d) When OP = WP WP = TP

OP = TP

i.e., cell has no further capacity to absorb any water.

- 32. (a) Water moves from higher water potential (Less negative) to lower water potential (more negative).
- 33. (b) Because of establishment of equilibrium.
- 34. (a) Due to endosmosis and suction pressure of the cell. Cell will get its original shape and size.
- 35. (d) In case of fully turgid cell, the net movement of water into the cell is stopped. The cell is in equilibrium with the water outside. The water potential in such case will be zero (0).
- 36. (a) Osmotic pressure of a solution is equivalent to the pressure, which must be exerted upon it to prevent the flow of solvent into it across a semipermeable membrane.
- (a) Osmotic Pressure Turgor Pressure = Diffusion Pressure Deficit (DPD).

Absorption of water and Ascent of sap

- (b) The absorption of water still occurs when concentration of outer soil water is more than root hair cell sap.
- 7. (d) Cohesion is the attraction between the molecules of the same substances. e.g., water-water transpiration pull: A tension or negative pressure develops in the water column present in tracheary elements. It exerts an upward pull over the water column called transpiration pull.
- (a) Physical theories believe that ascent of sap is a physical phenomenon.
- 12. (d) Tracheary elements are the part of xylem.
- (a) In mycorrhiza, fungal member helps in absorption of mineral and water.
- (b) Because inorganic salts are absorbed with water.
- 25. (c) When the concentration of the soil solutes is low, the absorption of water is increased. This is due to diffusion of water inside the absorbing cell. This is because water moves from high concentration (of water) to low concentration (of water). So when the soil has less solute the water concentration must be more and thus absorption of water by the cell will be more at the relatively high content of water.
- (d) Ascent of sap takes place by root pressure which develops by transpiration pull.

- 28. (d) A plant with deep and elaborate root system can absorb more water. Moreover, the number of root hairs will be more in a highly branched and elaborate root system, thus its more surface area will be in contact with water.
- 29. (a) When concentration of outer soil water is more than root hair cell sap, under such conditions exosmosis should occur, but it has been seen that water is still absorbed against concentration gradient.
- **30.** (b) It occurs in the form of film coating smaller soil particle. It is also called growth water.
- 31. (d) Force for absorption of water is generated in the cells of root itself. Osmotic and non-osmotic forces are involved in active water absorption.
- **32.** (b) Sap moves up the stem through the lumen of xylem vessels and tracheids.
- 34. (a) Diffusion of water from its pure state or dilute solution into a solution or stronger solution when the two are separated by a semipermeable membrane is termed as osmosis. In plants water supply is due to osmosis.
- 36. (d) In angiosperms, sap moves up the stem through the lumen of xylem vessels and trachieds and not through their walls.
- **38.** (c) A cell takes up water due to its suction pressure, (DPD) SP = OP TP.
- 40. (c) Water column remains intact despite gravitational pull because water molecules have a strong cohesion force amongst them due to presence of hydrogen bonds. Cohesion face provides a tensile strength to water column. It has a value of 45–207 atm.
- 41. (d) Here roots play passive role in water absorption, i.e., forces responsible for absorption of water are not generated in roots, but in upper parts of the plant, i.e., transpiration pull.
- **42.** (c) Water absorbing part of the young roots is root hair zone. It lies between 2–10 cm. from the root tip. Root hairs are tubular extension of epiblema cells.
- **43.** (a) ATPase may itself catalyze a direct transport of K^+ , or a Na^+/K^+ exchange pump.
- (a) Root pressure is caused by absorption of water through root hairs.

Factors affecting absorption of water and Ascent of sap

- (d) Soil temperature, soil aeration, relative humidity (R.H.), amount of soil water and transpiration are factors affect the absorption.
- (a) According to imbibitional theory (Sachs 1879), water moves upward in the stem through the imbibitional activity of the walls of the xylem vessels to be responsible for the ascent of sap.
- (c) Because transpiration rate is very high in sunny day.
- (b) Clay particles are tiny and sticky in nature, hence holding capacity is highest in clay soil.
- 7. (b) Increased amount of water in the soil beyond a certain limit results in poor aeration of the soil which retards metabolic activities of root cells like respiration and hence, the rate of water absorption is also retarded and magnitude of root pressure is very low (about 2 atms).

Transpiration (General) and Stomata

- (c) It brings rapid translocation of water in the plant to compensate the loss of water during transpiration.
- **4.** (b) Stomatal index (SI) = $\frac{S}{S+E} \times 100$

Plant	Numbers of stomata (S)	No. of epidermal cells (E)	SI	
Х	30	150	16.6	
Y	60	240	20.0	
Z	90	400	18.3	

So, the arrangement of plants in decreasing order of their stomatal index is, Y, Z, X.

- 6. (b) Cobalt chloride paper method is used to compare rate of transpiration on two surfaces of leaf. Cobalt chloride is blue in anhydrous state. In contact with water vapour it turns pink.
- (d) Transpiration occurs in plants, only from living cells.
 Evaporation occurs from any free surface. Both from living and nonliving surface.
- (b) Maximum loss of water by plant takes place through stomata.
- (d) Endodermis is internal layer which is not related with transpiration.
- 10. (a) About 98 percent of the water absorbed by land plants evaporates from the aerial parts and diffuses into the atmosphere.
- 16. (c) CAM plants are succulent or fleshy plants. The stomata of succulent plants remain closed during day and open during night to avoid water loss (scotoactive stomata).
- 18. (b) Such stomata are known as scotoactive stomata.
- 20. (c) Plants growing in dry conditions (xerophytes) develop some characters in leaves so as to reduce rate of transpiration like rolling of leaf during mid of the day e.g., Amophila.
- 22. (a) Barley type stomata open only for a few hours in the day time, otherwise they remain closed throughout the day and night. e.g., Cereals.
- 23. (a) Number of stomata per square cm is 1000 60,000 in different plant species. Stomatal frequency of trees and shrubs is higher than those of herbs.
- 24. (b) S = Number of stomata per unit area.E = Number of epidermal cells per unit area.
- 25. (d) Because Vallisneria is an aquatic plant.
- 29. (b) It is assumed that the upward movement of water through the plant requires the occurrence of transpiration.
- 33. (d) Because algae and fungi are not differentiate in root, stem and leaves and transpiration takes place from these parts. Submerged hydrophytes possess vestigeal stomata hence transpiration are absent.

- 34. (a) Such stomata are known as scotoactive stomata. This is a mechanism to reduce water loss due to transpiration. When they are situated in grooves and sometimes protected by hairs, the rate of transpiration is further decreased. Such adaptations are found in xerophytes. These are found in plants like Opuntia, Aloe, Bryophyllum etc.
- 35. (b) Lenticels are the areas in the bark of woody plants which are filled with loosely arranged cells known as complementary cells. Loss of water vapour through lenticels is called lenticular transpiration.
- **36.** (b) The outer wall of these cells is thin and inner wall is thick.
- 37. (a) Each stoma is bordered by two specialized epidermal cells called 'guard cells' which are generally kidney shaped or bean shaped but in grasses, guard cells are dumb-bell shaped.
- 38. (ac) Transpiration is a necessary evil for plants (water is continuously lost during the process even during stress but is important for ascent of sap and metabolism). Transpiration also occurs by lenticels.

Factors affecting transpiration

- (c) At low atmospheric pressure at high altitudes, the rate of transpiration is increased. The rate of transpiration is inversely proportional to the atmospheric pressure.
- 3. (a) Increase in temperature leads to opening of stomata even is night but within a certain physiological range. Again very high temperature leads to closing of stomata even in day (mid-day closure). Similarly very high wind velocity decreases transpiration by lowering temperature.
- 4. (d) Light affects the rate of transpiration directly by opening of stomata. In the absence of light or decrease in light intensity the stomata are closed and the stomatal transpiration is completely checked.
- 5. (d) In the case of hydroactive control abscisic acid (ABA) plays an important role in the closure of stomata, when ever there is shortage of water ABA is synthesized resulting in the closure of stomata.
- 6. (c) Increase in the temperature of the air decreases the humidity of the air and therefore more water is vapourised and lost from the transpiring surface. When soil is moist means availability of water are sufficient, stomata will open thus rate of transpiration increases.
- (a) If the atmosphere is very humid and relatively saturated its capacity to absorb water is low and the rate of transpiration is slowed down.
- 9. (d) Transpiration depends upon difference in vapour pressure of internal atmosphere of leaf and external environment (i.e., V.P. gradient) and it is, therefore, that no transpiration occurs when stomata are fully open but relative humidity is 100%.

- 11. (b) Temperature directly effects the transpiration. As the temperature rises so does the transpiration. Temperature in its turn is effected by light.
- 12. (d) If the atmosphere is humid, it reduces the rate of transpiration. When the air is dry, the rate of transpiration increases.
- 13. (d) Loss of half of the leaves of tree provide maximum harm to tree because rate of transpiration slows down and metabolic activity is also lowered but the plants remains alive in stressed condition.
- 16. (b) Mansfield (1965) reported that removal of CO₂ maintained stomatal opening even in the dark. Conversely, the stomata close in light if the CO₂ concentration is increase.

Mechanism of opening and Closure of stomata

- 6. (d) When K⁺ ions into the guard cells, stomata open and when K⁺ ions out, stomata close. K⁺ ion is necessary to maintain the turgidity of guard cells of stomata.
- 9. (a) Stomata open during day time because the guard cells prepare osmotically active substances by photosynthesis. As a result, their osmotic pressure increases and their turgor pressure increases due to endosmosis.
- 10. (d) Stomata in angiosperms open and close due to change of turgor pressure in cells are turgid state the stomatal aperture opens and when guard cells are in flaccid state the stomatal aperture closes.
- 12. (b) Endosmosis increases the turgidity of guard cells. The osmotic inflow of water into a cell enables a plant cell to attain turgidity.
- (c) Korper kappe theory its related to tissue system (Root and shoot).
- 15. (b) Linsbauer (1916) suggested that the removal of CO₂ by photosynthesis causes opening of stomata by changing the permeability of the guard cells to different kinds of solutes and guard cells are more permeable when the stomata are closed.
- 17. (b) Sometimes, a few epidermal cells in the vicinity of the guard cells become specialised in their shape and size and are known as subsidiary cells.
- 21. (c) In the evening leaf photosynthesis stops. Carbon dioxide concentration increases in the leaf interior. It results in decrease in pH. Glucose is phosphorylated to form glucose 6-phosphate. It is changed to glucose I-phosphate from which starch is synthesised.

Starch does not exert any osmotic potential and therefore, guard cells lose water to nearby epidermal cells. Their turgidity falls and the stomatal pore closes.

- 22. (d) As per "Active K+ transport mechanism" accumulation of K+ ions occurs in the guard cell during the day in response to light. It increases the turgidity of guard cells consequently stoma opens. During night, ions move out of the guard cells into surrounding epidermal cells consequently guard cells become flaccid and stomata close.
- 23. (b) Light causes photosynthesis which lead to reduction in CO₂ concentration → synthesis of glycolate → oxidation of glycolate → ATP synthesis → activation of K⁺ pump → movement of K⁺ in guard cell → movement of water into guard cells → swelling of guard cell → opening of stomata.

Guttation, Bleeding and Root pressure

- (a) Guttation is most common in plants growing in moist warm soil with their aerial parts surrounded by humid air.
- 4. (c) Exudation of liquid from the water pore or stoma is due to the development of a positive hydrostatic (root pressure) pressure in the xylem present in the vein ending. The pressure forces the liquid out through the hydathode.
- (c) Guttation, is the process in which water drops come outside by margins of leaves by hydathodes.
- 8. (b) Hydathodes are usually found on the margins and tips of the leaves. Each hydathode consists of a group of loosely arranged achlorophyllous or colourless and parenchymatous cells called epithem.
- (a) Guttation is found in herbaceous plant e.g., Garden nasturtium (Tropaelum najas), oat (Avena Sativa), Barley (Hordeum vulgare) and colocasia (Colocasia antiquorum) etc. growing in moist, warm soil and under humid conditions.
- (a) In guttation drops of liquid come out of the edges of leaves during night and early mornings.
- 14. (d) Bleeding takes place through injured organs of plants.
- (a) In night, root pressure will be maximum because in night transpiration is zero.

Scientists and Apparatus concerned

- (b) W. Ruhland (1912) and Hoffman (1925) described that, small pores are found on membranes the molecules which are small in size than pores of membrane are only passed through these membranes.
- (a) Scholander et.al. (1965) ever the first to measure the tension directly by using pressure chamber method.
- 3. (a) Traube (1867) proposed his "Haftdruck" or retention pressure theory. According to him the permeation of solutes through a membrane depended on their relative greatness of affinity towards the membrane substance as compared to that of water.

- 5. (a) Some stomata open during night and remain closed during the day time and found in lower surface. This type of stomatal opening is called scotoactive type. This mechanism was explained by Nishida (1963).
- (a) Yin and Tung (1948). Enzyme phosphorylase in guard cells are responsible for starch glucose interconversion.
- (a) It incorporates good points of scarth's classical pH theory and active K⁺ transport theory.
- (c) Zelitch (1963) proposed that stomata open due to production of glycolic acid by photorespiration in guard cells under low concentration of CO₂.
- (d) Hartt and his coworkers (1964) proposed that the movement of assimilates of a leaf can depend upon radiant energy.
- **12.** (a) Swanson and Whitney (1953) reported that translocation out of the leaf was highly sensitive to temperature. Optimum temperature for translocation.
- **13.** (a) The rate of absorption of water is approximately equal to the rate of transpiration.
- (d) Slatyer and Taylor (1960). According to him water potential is the chemical potential of water which is equivalent to DPD with negative sign.
- (d) Potometer used for transpiration and clinostat used for geotropism.
- 20. (a) Godlewsky (1884) proposed Relay pump theory.
- 21. (a) Munch mass flow or pressure flow Hypothesis: According to Munch (1930), the translocation of organic solutes takes place through phloem along a gradient of turgor pressure from the region of higher conc. of soluble solutes i.e., supply end to the region of lower conc. i.e., consumption end.
- 22. (c) Scholander et.al. (1965) were the first to measure the tension directly by using pressure chamber method or pressure bomb technique.

Translocation of organic solutes

- (d) According to curtis upward conduction of food also takes place through phloem. This view is based upon ringing experiments.
- (c) Food (carbohydrates) is translocated from leaves to roots and storage organs along the phloem in the form of sucrose. Downward translocation from leaves to stem and roots.
- 3. (d) Translocation of solutes mostly occurs in form of sucrose.
- 9. (a) It is the long distance movement of organic substnaces from the source or supply end (region of manufacture or storage) to the region of utilization or sink.
- 15. (a) The movement of the molecules of gas, liquids and solutes from the region of higher concentration to the region of lower concentration is known as diffusion.
- 20. (a) Girdling: Removal of bark (phloem) in a ring-like manner is called as girdling. Due to this the root will not get food and die.
- **23.** (b) *Munch mass flow*: This theory is based on difference in osmotic pressure in leaf mesophyll cells and root cells.

- (d) Boron is highly essential for translocation of sugar.
 Translocation of sucrose occurs in the form of sucrose borate complex.
- 30. (c) Ziegler (1956) believes that the diffusion of sugars from the mesophyll cells to the sieve tubes may occur against a concentration gradient.

Critical Thinking Questions

- (a) The intensity of the colour increases with the increase in temperature because at higher temperature the semi-permeability of the plasma membrane is gradually lost.
- (d) If a cell is placed in hypotonic solution, water start moving into the cell by the process of endosmosis and cell become turgid.
- 4. (c) The pressure potential is usually positive.
- 5. (b) Sucrose is non-ionizing substance whereas NaCl is ionizing and osmotic pressure of a solution of ionizing substance is greater than that of equimolar concentration of a non-ionizing substance.
- 6. (b) Covering of the leaf surface with wax will stop cuticular transpiration, block stomata, stop stomatal transpiration and gaseous exchange on that surface.
- (a) In water-logged soil, plants are unable to absorb water, thus they do not grow properly.
- 9. (d) K⁺ are balanced by organic anions i.e., malate and some Cl⁻ ions are also taken in to neutralize a small percentage of K⁺, this mechanism is controlled the turgidity of guard cells.
- 10. (b) Stephentiales (1727) coined the term root pressure. Root pressure is developed when rate of water absorption is more than the rate of transpiration.
- (b) For C₃ plants the ratio is 500–800. It shows that C₄ plants transpire less and are more efficient in conserving water than most of C₃ plants.
- 12. (c) The water is held tightly around the soil particles due to cohesive forces. Hygroscopic water can not be easily removed by the plants. This type of water in soil is not available to plants.
- 13. (c) Taller plants like Eucalyptus need higher pressure to raise the water up. While the value of root pressure ranges from 2.5 atmospheres. A pressure of about 20 atm. is required to raise the water to tops of tall trees.
- **16.** (c) Ringing or girdling experiment was first performing by Hartig (1937). This experiment suggests that in absence of phloem, downward translocation of food is stopped.
- 17. (b) According to passive absorption theory, the forces responsible for absorption of water originate not in the cells of roots but in the cells of transpiring shoots.
- 18. (b) Water is absorbed by the root hair due to osmotic differences between soil water and cells sap.
- 19. (b) During absorption of water by roots the water potential of cell sap is lower than that of pure water. Due to higher osmotic pressure of water in the root hair, the water from soil passes into the root hair.

Assertion and Reason

- (a) Hartig performed ringing experiment to show path of water through xylem. Xylem is basic tissue for conduction of water in higher plants. It has vessels and tracheids which are well adapted for water translocation.
- 2. (a) In plants, usually maximum water uptake is found in the root hair zone, as this part has the maximum surface area due to the presence of root hairs. These root hairs also withdraw from interspaces, which are not in contact with epiblema of the root. Whereas, the zone of mature cells cannot absorb water because of the presence of impermeable and suberised surface layer.
- 3. (a) Sieve tubes are the conducting elements of phloem (a permanent vascular tissue which conducts organic food in plant body) which are elongated tubular channels formed by end to end union of numerous cells. The septa between individual sieve tube cells or sieve elements are bulged out. They are called sieve plates possessing a number of perforations (sieve pores or sieve pits) and helps in conduction of food.
- 4. (b) In arid and unirrigated areas crop plants cannot be grown because of excessive transpiration and reduced water availability. Substances that reduce the rate of transpiration are called antitranspirants. e.g., ABA. Antitranspirants will maintain a favourable internal water balance even in cases of very low water availability. It will allow farmers to grow crop profitably in unirrigated areas and help foresters to plant trees even in extreme arid or desert areas.
- (c) Oil is a nonpolar molecule, which means that it does not form hydrogen bonds with water and therefore, does not dissolve.
- 6. (d) Film forming chemicals check transpiration by forming a thin film on the transpiring surface. They are sufficiently permeable to carbon dioxide and oxygen to allow photosynthesis and respiration but prevent movement of water vapours through them. There such chemicals can be used as antitranspirants.
- 7. (a) Many plant movements are produced due to reversible turgor changes in the cells. The opening and closing of stomata are caused by gain and loss of turgidity by their guard cells. They are hence often called "turgor operated valves".
- 8. (b) Flowers, young stems and other softer organs are able to maintain their form due to turgidity or TP (turgor pressure). In case of loss of turgidity, the shoots droop down and the leaves show wilting. Turgor pressure (pressure potential or hydrostatic pressure) keeps a check on the excessive entry of water into cells.
- 9. (e) In case of loss of turgidity, the shoots droop down and the leaves show wilting. In wilting the individual cells of leaves and other softer parts become flaccid, due to loss of water from their interior. In temporary wilting, plants gain their turgidity when they are given water. If the soil does not obtain water periodically, the recovery may be only partial or it may not occur at all. The latter condition is known as permanent wilting.
- 10. (a) A high osmotic pressure has been found to protect the plants against drought and frost injury. Seeds and spores are similarly able to pass through the unfavourable periods due to high osmotic pressure (or low solute potential).

- 11. (a) Turgor pressure is the pressure which develops in the confined part of an osmotic system due to osmotic entry of water into it. It is also called hydrostatic pressure or pressure potential. The force exerted by the cell wall over the protoplast is called wall pressure. Normally wall pressure is equal and opposite to turgor pressure except when the cell becomes flaccid.
- 12. (b) Shrinkage of the protoplast of a cell from its cell wall under the influence of a hypertonic solution is called plasmolysis. Hypertonic solution causes exosmosis or withdrawl of water from the central vacuole of cell. The pressure on the wall is simultaneously reduced and the elastic wall contracts causing a reduction in cell size. This is first stage of plasmolysis called limiting plasmolysis. Initially the protoplast withdraws itself from the corners. This stage is known as incipient plasmolysis. Due to continued exosmosis, protoplast shrinks further and withdraws from the cell wall except at one or a few points. It is known as evident plasmolysis. Cells cannot survive in such case.
- 13. (b) The accumulation of CO_2 in the soil appears to have a greater inhibitory effect on water absorption than do lowered oxygen tensions. An increase in CO_2 causes an increase in the viscosity of protoplasm and a decrease in the roots permeability to water thereby bringing about a retardation in water absorption.
- 14. (c) Sap is water with dissolved ingredients. The upward movement of water from roots towards the tips of stem branches and their leaves is called ascent of sap. It occurs through the tracheary elements of xylem.
- 15. (c) Plants have the potentiality to absorb water through their entire surface right from root, stem, leaves, flowers, etc. However, as water is available mostly in the soil, only the underground root system is specialized to absorb water. In roots, the most efficient region of water absorption is the root hair zone.
- 16. (c) The optimum or maximum amount of water retained per unit dry weight of soil after the stoppage of gravitational flow is called field capacity. It is 25-35% in common loam soils. Soil moisture beyond field capacity produces water logging.
- 17. (e) Although vessels and tracheids are oriented in the plant in a vertical direction with respect to their long axis and water movement is predominantly in this direction, lateral water movement does take place. Numerous pits through which water may pass perforate the side walls of vessel elements and tracheids. The xylem ray parenchyma greatly facilitates the lateral transport of water and nutrients.
- 18. (a) Light induces opening of stomata and increase the temperature, both these factor help in increase of transpiration, while darkness causes closure of stomata and reduces the rate of transpiration. Transpiration depends on closure and opening of stomata.
- 19. (a) Waxy coating, thick cuticle, sunken stomata, hairy surface reduce transpiration and are characters of xerophytes which grow in places where water is not available in much quantity.
- 20. (d) The intercellular spaces of the transpiring organ is almost saturated with water vapours. When the stomata are open the water vapours are drawn from the substomatal cavities to the outside air due to high DPD of the latter. This increases the DPD of the substomatal air which draws more water vapours from the intercellular spaces. The latter in turn get water vapours from the wet walls of mesophyll cells.

ET Self Evaluation Test

- Imbibition process involves
 - (a) Both diffusion and capillary action
 - (b) Only diffusion
 - (c) Only capillary action
 - (d) None of the above
- 2. In the process of osmosis in the cell
 - (a) Both cell wall and protoplasm will act as a membrane
 - (b) Entire protoplast act as a membrane
 - (c) Only outermost layer of protoplasm act as a membrane
 - (d) Only cell wall act as a membrane
- 3. Osmotic pressure is highest in

[RPMT 1992]

- (a) Xerophytes
- (b) Lithophytes
- (c) Halophytes
- (d) Mesophytes
- In which part of the plant water is stored [CPMT 1996]
 - (a) Roots
- (b) Stem
- (c) Leaves
- (d) Bark
- 5. Which of the following is done during ringing experiment

[CPMT 2010]

- (a) Bark is removed
- (b) Pith is removed
- (c) Xylem is removed
- (d) All of these
- 6. The most abundant intracellular cation is [NEET 2013]
 - (a) K+
- (b) Na+
- (c) Ca++
- (d) H+
- 7. Which of the following statements is/are not true
 - A. In CAM plants stomata open during dark and remain closed during the day
 - B. Role of Na⁺ in stomatal opening is now universally accepted
 - The water potential of root cells is higher than the water potential of soil
 - D. Capillarity theory is the most accepted theory of water movement through plants
 - E. The walls of xylem vessels made up of ligno-cellulose have strong affinity for water molecules

[Kerala PMT 2008]

- (a) B, C and E only
- (b) B, C and D only
- (c) A, B and C only
- (d) B and C only
- (e) A and E only

- 10. Which is the most important precaution to be observed in finding out the rate of transpiration through Ganong's potometer
 - (a) A broad leaf plant need to be selected
 - (b) The experimental shoot should be obliquely cut
 - (c) The shoot should be cut under water
 - (d) Apparatus to be filled with water
- In the resting state of the neutral membrane, diffusion due to concentration gradients, if allowed, would drive

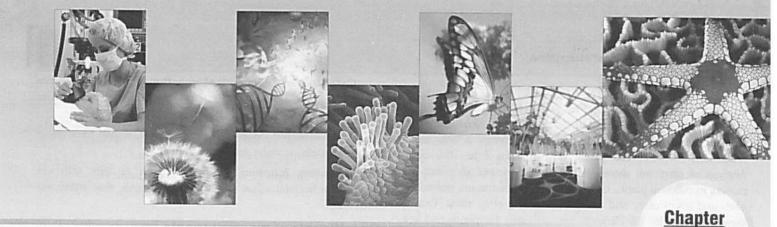

[CBSE PMT 2004]

- (a) Na+ into the cell
- Na+ out of the cell
- (c) K+ into the cell
- (d) K⁺ and Na⁺ out of the cell

Answers and Solutions

1	a	2	C	3	C	4	C	5	d
6	a	7	b	8	a	9	b	10	c
11	a	10000		- Marie	B com	100000		(850	100

- 2. Outermost layer of cell i.e., plasma membrane acts as semipermeable membrane.
- 3. Because halophytes are the plants of saline habitat.
- 9. All plants do not show guttation. It is restricted to about 345 genera of herbaceous and some woody plants. e.g., Garden Nasturtium, Oat, Balsum, Tomato etc.
- 10. The shoot should be cut under water because prevent air from entering the vessels.

4.2

Mineral Nutrition

Organisms require many organic and inorganic substances to complete their life cycle. All such substances which they take from outside constitute their nutrition. On the basis of their nutritional requirements, organisms can be classified into heterotrophs and autotrophs.

All non-green plants and animals, including human beings, are heterotrophs. Autotrophic green plants obtain their nutrition from inorganic substances which are present in soil in the form of minerals, which are known as mineral elements or mineral nutrients and this nutrition is called mineral nutrition.

Essential mineral elements

An essential element is defined as 'one without which the plant cannot complete its life cycle, or one that has a clear physiological role'. Therefore, in 1939 Arnon and Stout proposed the following characters for judging the criteria of essentiality of an element in the plant:

- (1) The element must be essential for normal growth and reproduction, which cannot proceed without it.
- (2) The requirement of the element must be specific and cannot be replaced by another element.
- (3) The requirement must be direct that is, not the result of any indirect effect e.g., for relieving toxicity caused by some other substance.

Essential elements are divided into two broad categories, based on the quantity in which they are required by plants. Macroelements and micro-elements. Their ionic forms are respectively called macronutrients and micronutrients. Mineral salts dissolved in soil solution are constantly passing downwards along with percolating (gravitational) water. The phenomenon is called leaching. Leaching is more in case of anions.

Macronutrients (Macroelements or major elements) :

Which are required by plants in larger amounts (Generally present in the plant tissues in concentrations of 1 to 10 mg per gram of dry matter). Of the non-essential functional elements, silicon and sodium often occur in the range of macroelements. Macroelements are usually involved in the synthesis of organic molecules and development of osmotic potential.

Micronutrients (Microelements or minor elements or trace elements): Which are required by plants in very small amounts, i.e., in traces (equal to or less than 0.1 mg per gram dry matter). Cobalt, vanadium, aluminium and nickel, may be essential for certain plants. Microelements are mostly involved in the functioning of enzymes, as cofactors or metal activators. The usual concentration of essential elements in higher plants according to D.W. Rains (1976) based on the data of Stout are as follows:

Table: 4.2-1

Elements	% of dry weight
Macro	nutrients
Carbon	45
Oxygen	45
Hydrogen	6
Nitrogen	1.5
Potassium	1.0
Calcium	0.5
Magnesium	0.2
Phosphorus	0.2
Sulphur	0.1
Micro	nutrients
Chlorine	0.01
Iron	0.01
Manganese	0.005
Boron	0.002
Zinc	0.002
Copper	0.0001
Molybdenum	0.0001

Plant analysis

Ash analysis: The plant tissue is subjected to a very high temperature (550-600°C) in an electric muffle furnace and is reduced to ash. The plant ash left behind forms a very small proportion of plants dry weight ranging from 2 to 10% only. Analysis of plant ash shows that about 92 mineral elements are present in different plants. Out of these, 30 elements are present in each and every plant and rest are in one or other plant. Out of these 30 elements, 16 elements are necessary for plants and are called essential elements.

Solution culture (Hydroponics): In this method plants are grown in nutrient solutions containing only desired elements. To determine the essentiality of an element for a particular plant, it is grown in a nutrient medium that lacks or is deficient in this element.

The growing of plants with their roots in dilute solutions of mineral salts instead of soil led to increased understanding of plant nutrition. This cultivation of plants by placing the roots in nutrient solution is called hydroponics. Probably the first recorded use of soilless culture was by Woodward in 1699. By 1860, the culture solution technique was modernized by Sachs and he showed the essentiality of nitrogen for plant growth.

Another significant worker for studying the essentiality of elements was Knop (1865). The method of growing plants in aqueous nutrient solutions as employed by Sachs and Knop is used experimentally and commercially today and known as hydroponic culture. Now a days a chelating agent Na²-EDTA (Disodium salt of ethylene diamine tetra acetic acid. EDTA (Ethylene diamine tetra-acetic acid) is a buffer which is used in tissue cultures is added.

Sand culture : Here plants are grown in inert sand + nutrient solution. Main advantage is that roots get natural environment and proper aeration.

Aeroponics: In this practice, plants are grown with their roots bathed in nutrients mist. This method has been successfully used in growing *Citrus* and olive.

Major role of nutrients

Various elements perform the following major roles in the plants:

Construction of the plant body: The elements particularly C, H and O construct the plant body by entering into the constitution of cell wall and protoplasm. They are, therefore, referred to as framework elements. Besides, these (C, H and O) N, P and S, Mg and Fe also enter in the constitution of protoplasm. They are described as protoplasmic elements.

Maintenance of osmotic pressure: Various minerals present in the cell sap in organic or inorganic form maintain the osmotic pressure of the cell.

Maintenance of permeability of cytomembranes : The minerals, particularly Ca^{++} , K^+ and Na^+ maintain the permeability of cytomembranes.

Influence the pH of the cell sap : Different cations and anions influence on the pH of the cell sap.

Catalysis of biochemical reaction: Several elements particularly Fe, Ca, Mg, Mn, Zn, Cu, Cl act as metallic catalyst in biochemical reactions.

Toxic effects: Minerals like *Cu*, *As*, etc. impart toxic effect on the protoplasm under specific conditions.

Balancing function : Some minerals or their salts act against the harmful effect of the other nutrients, thus balancing each other.

Specific role of macronutrients

The role of different elements is described below:

(1) Carbon, hydrogen and oxygen: These three elements, though can not be categorised as mineral elements, are indispensible for plant growth. Carbon, hydrogen and oxygen together constitute about 94% of the total dry weight of the plant. Carbon is obtained from the carbon dioxide present in the atmosphere. It is essential for carbohydrate and fat synthesis. Hydrogen and oxygen would be obtained from water which is absorbed by the plants from the soil. Some amount of oxygen is also absorbed from the atmosphere.

(2) Nitrogen

Source : The chief source of nitrogen for green plants is the soil. It is absorbed mainly in the form of nitrate ions (NO_3^-) . The major sources of nitrate for the plants are sodium nitrate, potassium nitrate, ammonium nitrate and calcium nitrate.

Functions: Nitrogen is an essential constituent of proteins, nucleic acids, vitamins and many other organic molecules as chlorophyll. Nitrogen is also present in various hormones, coenzymes and ATP etc. It plays an important role in protein synthesis, respiration, growth and in almost all metabolic reactions. It also intensifies colouration in apple.

Deficiency symptoms

- (i) Impaired growth
- (ii) Yellowing of leaves (appearing first in older leaves) due to loss of chlorophyll, i.e., chlorosis.
- (iii) Development of anthocyanin pigmentation in veins, sometimes in petioles and stems.
 - (iv) Delayed or complete suppression of flowering and fruiting.

Excessive supply of nitrogen produces following symptoms:

- (i) Increased formation of dark green leaves.
- (ii) Poor development of root system.
- (iii) Delayed flowering and seed formation.

(3) Phosphorus

Source : Phosphorus is present in the soil in two general forms, organic and inorganic. Organic compounds are decomposed and phosphorus is made available to plants in inorganic form. Soil solution contains phosphorus in inorganic forms as the phosphate ions obtained as $H_2PO_4^-$ and HPO_4^{2-} . When pH is low phosphate ions are present in the form of $H_2PO_4^-$. When pH is high, phosphate ions are represented in HPO_4^{2-} .

Functions

- (i) Phosphorous is present abundantly in the growing and storage organs such as fruits and seeds. It promotes healthy root growth and fruit ripening by helping translocation of carbohydrates.
- (ii) It is present in plasma membrane, nucleic acid, nucleotides, many coenzymes and organic molecules as ATP.
- (iii) Phosphorus plays an indispensable role in energy metabolism *i.e.*, hydrolysis of pyrophosphate. Thus it is required for all phosphorylation reactions.

Deficiency symptoms

- (i) Leaves become dark green or purplish.
- (ii) Sometimes development of anthocyanin pigmentation occurs in veins which may become necrotic (Necrosis is defined as localised death of cells).
 - (iii) Premature fall of leaves.
- (iv) Decreased cambial activity resulting in poor development of vascular bundles.
 - (v) Sickle leaf disease.

(4) Sulphur

Source: Sulphur is present as sulphate SO_4^{2-} in mineral fraction of soil. In industrialized areas, atmospheric sulphur dioxide (SO_2) and sulphur trioxide (SO_3) ; in low concentration may be important sources of sulphur nutrition.

Functions

- (i) Sulphur is a constituent of amino-acids like cystine, cysteine and methionine; vitamins like biotin and thiamine, and coenzyme A.
- (ii) It increases the nodule formation in the roots of leguminous plants. It favours soluble organic nitrogen and there is decrease in the quantity of soluble nitrogen with its increase.
- (iii) The characteristic smell of mustard, onion and garlic is due to the presence of sulphur in their volatile oils.
- (iv) Sulphur in plants is required in stem and root tips and young leaves. It is remobilised during senescence.

Deficiency symptoms

- (i) Leaves remain small and turn pale green i.e., symptoms of chlorosis. Chlorosis affects young leaves more because of immobile property of the sulphur. The young leaves develop orange, red or purple pigment.
- (ii) Leaf tips and margins roll downwards and inwards e.g., tobacco, tea and tomato.
 - (iii) Delayed flowering and fruiting.
- (iv) Apical growth is retarded whereas premature development of lateral buds starts.
 - (v) The tea yellow disease is caused in tea plants.
 - (vi) Decrease in stroma lamellae and increase in grana stacking.
- (vii) Increase in starch and sucrose accumulation, and decrease in reducing sugars.

(5) Potassium

Source : Source of K^+ to the plants is inorganic compounds like potassium sulphate, potassium nitrate, etc. Potassium is usually present in sufficient amount in clay soils. It contains approximately 0.3 to 6.0 percent of whole plant. In seeds, it is found in less amount.

Functions

- (i) It differs from all other macronutrients in not being a constituent of any metabolically important compound.
 - (ii) It is the only monovalent cation essential for the plants.
- (iii) It acts as an activator of several enzymes including DNA polymerase.
- (iv) It is essential for the translocation of photosynthates, opening and closing of stomata, phosphorylation, synthesis of nucleic acid and chlorophyll.

It takes part in the formation of cell membrane and it is also responsible for maintenance of turgidity of cells.

Deficiency symptoms

- (i) Mottled chlorosis followed by the development of necrotic areas at the tips and margins of the leaves.
- (ii) K^+ deficiency inhibits proteins synthesis and photosynthesis. At the same time, it increases the rate of respiration.
- (iii) The internodes become shorter and root system is adversely affected.
 - (iv) The colour of leaves may turn bluish green.
- (v) Widespread blackening or scorching of leaves may occur as a result of increased tyrosinase activity.
 - (vi) Rosette or bushy habit of growth may be seen in plants.

Destruction of pith cells of tomato and increased differentiation of phloem elements.

(6) Calcium

Source: It is absorbed by the plants in the form of Ca^{2+} from calcium carbonate etc. It occurs abundantly in a non-exchangeable form such as anorthite $(CaAl_2,Si_2O_8)$. Much of the exchangeable calcium of the soil is absorbed on to the surface of clay micelle.

Functions

- (i) It is necessary for formation of middle lamella of plants where it occurs as calcium pectate.
- (ii) It is necessary for the growth of apical meristem and root hair formation.
- (iii) It acts as activator of several enzymes, e.g., ATPase, succinic dehydrogenase, adenylate kinase, etc.
- (iv) Along with Na^+ and K^+ it maintains the permeability of plasma membrane.
- (v) It is involved in the organisation of spindle fibres during mitosis.
 - (vi) It antagonises the toxic effects of Na^+ and Mg^{++} .
- It is essential for fat metabolism, carbohydrate metabolism, nitrate assimilation and binding of nucleic acids with proteins.

Deficiency symptoms

- (i) Ultimate death of meristems which are found in shoot, leaf and root tips.
- (ii) Chlorosis along the margins of young leaves, later on they become necrotic.
 - (iii) Distortion in leaf shape.
 - (iv) Roots poorly developed or may become gelatinous.
- (v) Young leaves show malformation and leaf tips becomes hooked.
- (vi) Its deficiency checks flowering and causes the flowers to fall early.
 - (vii) Potato tubers become small and malformed.

(7) Magnesium

Source: Magnesium occurs in the soil in the form of magnesite $(MgCO_3)$, dolomite $(MgCO_3)$, $CaCO_3$, magnesium sulphate $(MgSO_4)$ and as silicates. It is absorbed from the soil in the form of (Exchangeable cation) ions (Mg^{++}) . It is easily leached and thus become deficient in sandy soils during rainy season.

Functions

- (i) It is an important constituent of chlorophyll.
- (ii) It is present in the middle lamella in the form of magnesium pectate.
- (iii) It plays an important role in the metabolism of carbohydrates, lipids and phosphorus.
 - (iv) It acts as activator of several enzymes.
- (v) It is required for binding the larger and smaller subunits of ribosomes during protein synthesis.

Deficiency symptoms

- (i) Interveinal chlorosis followed by anthocyanin pigmentation, eventually necrotic spots appear on the leaves. As magnesium is easily transported within the plant body, the deficiency symptoms first appear in the mature leaves followed by the younger leaves at a later stage.
 - (ii) Stems become hard and woody, and turn yellowish green.
- (iii) Depression of internal phloem and extensive development of chlorenchyma.

Specific role of micronutrients

(1) Iron

Source : It is present in the form of oxides in the soil. It is absorbed by the plants in ferric (Fe^{3+}) as well as ferrous (Fe^{2+}) state but metabolically it is active in ferrous state. Its requirement is intermediate between macro and micro-nutrients.

Functions

- (i) Iron is a structural component of ferredoxin, flavoproteins, iron prophyrin proteins (Cytochromes, peroxidases, catalases, etc.)
- (ii) It plays important roles in energy conversion reactions of photosynthesis (phosphorylation) and respiration.
 - (iii) It acts as activator of nitrate reductase and aconitase.
 - (iv) It is essential for the synthesis of chlorophyll.

Deficiency symptoms

- (i) Interveinal chlorosis particularly in younger leaves, the mature leaves remain unaffected.
- (ii) It inhibits chloroplast formation due to inhibition of protein synthesis.
 - (iii) Stalks remain short and slender.
 - (iv) Extensive interveinal white chlorosis in leaves.
- (v) It may develop necrosis aerobic respiration severely affected.
- (vi) In extreme deficiency scorching of leaf margins and tips may occur.

(2) Manganese

Source: Like iron, the oxide forms of manganese are common in soil. However, manganese dioxide (highly oxidised form) is not easily available to plants. It is absorbed from the soil in bivalent form (Mn^{++}) . Oxidising bacteria in soils render manganese unavailable to plants at pH ranging from 6.5 to 7.8.

Functions

- (i) It acts as activator of enzymes of respiration (malic dehydrogenase and oxalosuccinic decarboxylase) and nitrogen metabolism (nitrite reductase).
 - (ii) It is required in photosynthesis during photolysis of water.
- (iii) It decreases the solubility of iron by oxidation. Hence, abundance of manganese can lead to iron deficiency in plants.

Deficiency symptoms

- (i) Chlorosis (interveinal) and necrosis of leaves.
- (ii) Chloroplasts lose chlorophyll, turn yellow green, vacuolated and finally perish.
- (iii) 'Grey speck disease' in oat appears due to the deficiency of manganese, which leads to total failure of crop.
 - (iv) 'Marsh spot's in seeds of pea.
 - (v) Deficiency symptoms develop in older leaves.
 - (3) Copper

Source : Copper occurs in almost every type of soil in the form of complex organic compounds. A very small amount of copper is found dissolved in the soil solution. It is found in natural deposits of chalcopyrite $(CuFeS_2)$.

Functions

- (i) It activates many enzymes and is a component of phenolases, ascorbic acid oxidase, tyrosinase, cytochrome oxidase.
- (ii) Copper is a constituent of plastocyanin, hence plays a role in photophosphorylation.
 - (iii) It also maintains carbohydrate nitrogen balance.

Deficiency symptoms

- (i) Both vegetative and reproductive growth are reduced.
- (ii) The most common symptoms of copper deficiency include a disease of fruit trees called 'exanthema' in which trees start yielding gums on bark and 'reclamation of crop plants', found in cereals and legumes.
- (iii) It also causes necrosis of the tip of the young leaves (e.g., Citrus). The disease is called 'die back'.

- (iv) Carbon dioxide absorption is decreased in copper deficient trees.
 - (v) Wilting of entire plant occurs under acute shortage.
- (vi) Grain formation is more severely restricted than vegetative growth.

(4) Molybdenum

Source: It is available to the plants mostly as molybdate ions. It is required in extremely small quantities by plants.

Functions

- (i) Its most important function is in nitrogen fixation because it is an activator of nitrate reductase.
 - (ii) It is required for the synthesis of ascorbic acid.
- (iii) It acts as activator of some dehydrogenases and phosphatases.

Deficiency symptoms

- (i) Mottled chlorosis is caused in the older leaves as in nitrogen deficiency, but unlike nitrogen-deficient plants, the cotyledons stay healthy and green.
- (ii) It is also known to inhibit flowering, if they develop, they fall before fruit setting.
 - (iii) It leads to drop in concentration of ascorbic acid.
- (iv) Its deficiency causes 'whiptail disease' in cauliflower and cabbage. The leaves first show an interveinal mottling and the leaf margins may become gray and flaccid and finally brown.

(5) Zinc

Source: Zinc occurs in the soil in the form of ferromagnesian minerals like magnetite, biotite and hornblende. Increase in soil *pH* decreases the availability of zinc.

Bivalent form of zinc (Zn^{++}) is exchangeable and is readily available in the soil. Plants require this mineral only in traces and its higher concentrations are highly toxic.

Functions

- (i) It is required for the synthesis of tryptophan which is a precursor of indole acetic acid-an auxin.
- (ii) It is a constituent of enzymes like carbonic anhydrase, hexokinase, alcohol dehydrogenase, lactic dehydrogenase and carboxypeptidase.
- (iii) It is required for metabolism of phosphorus and carbohydrates.
- (iv) Zinc also appears to play an important role in protein synthesis because in its absence there is substantial increase in soluble nitrogenous compounds.

Deficiency symptoms

- (i) The first symptom appears in the form of interveinal chlorosis of the older leaves, starting at the tips and the margins.
- (ii) Growth becomes stunted due to formation of smaller leaves and shortened internodes. Reduced stem growth is due to less synthesis of auxin.
- (iii) The leaves become distorted and sickle shaped and get clustered to form rosettes. This effect is known as 'little leaf disease'.
- (iv) In maize, zinc deficiency produces 'white bud disease' which leads to greatly reduced flowering and fruiting as well as poorly differentiated root growth.

(v) Its deficiency causes khaira disease of rice and mottled leaf of apple, Citrus and walnut.

(6) Boron

Source : Boron is present in the soil in very small amounts. It appears in exchangeable soluble and nonexchangeable forms in the soil BO_3^{3-} or $B_4O_7^2$. It is absorbed from the soil as boric acid (H_3BO_3) and tetraborate anions.

Functions

- (i) It facilitates the translocation of sugars.
- (ii) It is involved in the formation of pectin.
- (iii) It is also required for flowering, fruiting, photosynthesis and nitrogen metabolism.
- (iv) Boron is required for uptake and utilisation of Ca^{2+} , pollen germination, seed germination and cell differentiation.
 - (v) It regulates cellular differentiation and development.

Deficiency symptoms

- (i) The first major symptom of boron deficiency is the death of shoot tip because boron is needed for DNA synthesis.
- (ii) Generally flowers are not formed and the root growth is stunted.
- (iii) The leaves develop a thick coppery texture, they curve and become brittle.
- (iv) Some of the physiological diseases caused due to boron deficiency are internal cork of apple, top rot of tobacco, cracked stem of celery, browning of cauliflower, water core of turnip, hard fruit of Citrus and heart rot of sugar beets and marigold. These diseases can be cured by application of small doses of sodium tetraborate in the soil.
- (v) Its deficiency checks the cell division of cambium but continues cell elongation.

(7) Chlorine

Source : It is absorbed from the soil as chloride ions. Hence, it is rarely supplied as fertilizer.

Functions

- (i) It is required for photolysis of water during photosynthesis in photosystem-II.
- (ii) In tobacco, it increases water volume inside the cell and also regulates carbohydrate metabolism.
- (iii) With Na^+ and K^+ , chlorine helps in determining solute concentration and anion cation balance in the cells.
 - (iv) It is essential for oxygen evolution in photosynthesis.

Deficiency symptoms

- (i) The deficiency symptoms of chlorine consist of wilted leaves which later become chlorotic and finally attain a bronze colour.
- (ii) Roots become stunted or thickened and club shaped and fruiting is reduced.
 - (iii) Photosynthesis is also inhibited.

Critical elements : Macroelements which become commonly deficient in the soils are called critical elements. They are in number–N, P and K most fertilisers contain critical elements. They are called complete fertilisers.

Mechanism of absorption of mineral elements

Plants obtain minerals from soil where these are dissolved in soil solution or are present adsorbed to colloidal clay particles.

- $\ \square$ Mineral salt absorption is **independent** of water absorption.
- ☐ Maximum mineral salt absorption occurs by **zone of elongation**. No mineral salt absorption occurs by root hair zone. Mineral salt absorption occurs directly by cells of epiblema and not by root hair.
- Mineral salts are absorbed mostly in form of ions, i.e., anions and cations.

Various theories have been proposed to explain the mechanism of mineral salt absorption and can be placed under the following two categories.

(1) Passive absorption: Absorption of ions without the use of metabolic energy is known as passive absorption. This type of absorption is carried out by purely physical forces.

Briggs and Robertson (1957) demonstrated the passive absorption of ions by root system. They showed:

- Mineral salt absorption is not affected by temperature and metabolic inhibitors.
- (ii) Rapid uptake of ions occurs when plant tissues are transferred from a medium of low concentration to high concentration.

Some of the important theories explaining the mechanism of passive absorption of minerals are given below :

Mass flow hypothesis: According to Hylmo (1953, 1955), the ion absorption increases with increase in transpiration. The ions have been considered to move in a mass flow with water from the soil solution through the root and eventually to the shoot. The theory was supported by Kramer (1956), Russel and Barber (1960), etc. Later, Lopushinsky (1960) using radioactive P^{32} and Ca^{45} , has supported this experiment.

Simple diffusion hypothesis: According to this hypothesis, if the concentration of solutes inside the plant is lower than the soil, the mineral ions are thought to migrate into the root by simple diffusion. As a result, a state of equilibrium is reached. The part of plant cell or tissue that permits free diffusion is sometimes called outer space. The apparent volume that accomodates these ions has been referred to by some workers as apparent free space. The accumulation of ions in the cell against concentration gradient can not be explained by this concept.

Facilitated diffusion hypothesis: According to this concept, the ions are transported across the membrane by a carrier protein. When the ions enter the cell through protein channels and not through the lipid layer the phenomenon is called facilitated diffusion.

Ion exchange hypothesis : According to this view the ions adsorbed to the cell surface are exchanged from the external medium. A cation is exchanged for a cation and anion for anion. If a particular ion is absorbed by the plant, in exchange it offers H^+ or OH^- ions which are made available by the dissociation of water molecule.

There are two theories to explain the mechanism of ion exchange.

- (i) Contact exchange theory: According to this theory, ions are not completely static, they are always oscillating around their absorption surface and when the oscillation volume of the ions on the roots and on the colloidal particles overlap each other, ion exchange occurs. An equilibrium is maintained between the dissolved fractions as any depletion in the soil solution is covered by movement of ions.
- (ii) Carbonic acid exchange theory: In this case, CO_2 released by roots during respiration reacts with water to produce carbonic acid which dissociates into hydrogen ions and bicarbonate ions. Hydrogen ion exchanges itself with the cations adsorbed on the colloidal particles and the bicarbonate ions release the adsorbed anions to supply both anions and cations nearby.

 $H_2O + CO_2$ H_2CO_3 $H^+ + HCO_3^ \begin{array}{c} \text{Root} & H^+ \\ \text{Clay} \\ \text{micelle} \end{array}$

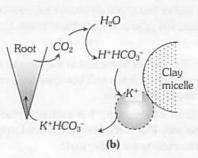

Fig: 4.2-1 Diagrammatic representation of (a) The contactexchange theory and (b) The carbonic acid exchange theory

Donnan equilibrium: This mechanism, given by F.G. Donnan (1927), takes into account the effect of non-diffusible ions, which may be present on one side of the membrane. Unlike diffusible ions, the membrane is not permeable to non-diffusible ions. Such ions are termed as fixed ions. They may be anions or cations. In a system, in which there are no fixed ions, there are equal number of anions and cations on both sides of the membrane at equilibrium. But in Donnan equilibrium, in order to balance the charge of the fixed ions (say anions), more ions of the other charge (say cations) would be required.

Mathematically, the Donnan equilibrium may be represented by following equation :

 $[C_i^+][A_i^-] = [C_0^+][A_0^-]$

Here: C_i^+ = Cations inside; C_o^+ = Cations outside

 A_i^- = Anions inside; A_0^- = Anions outside

 $\frac{Positive\ ions\ inside}{Positive\ ions\ outside} = \frac{Negative\ ions\ outside}{Negative\ ions\ inside}$

UNIVERSAL BOOK DEPOT 1960

(2) Active absorption: Generally, the lipid-protein membrane of a cell is largely permeable to free ions. The energy is considered to be involved in the transport of such free ions across the membrane. The absorption of ions, involving use of metabolic energy, is called active absorption. Energy used in these mechanisms comes from metabolic activities, especially respiration. Mineral absorption is mainly active process. Hoagland (1944) indicated active ion absorption and their (ions) accumulation against concentration gradient in green algae Nitella and Valonia.

Following evidences show the involvement of metabolic energy in the absorption of mineral salts :

- (i) Higher rate of respiration increases the salt accumulation inside the cell.
 - (ii) Respiratory inhibitors check the process of salt uptake.
- (iii) By decreasing oxygen content in the medium, the salt absorption is also decreased.

Active transport is necessary for living cells because certain substances must be concentrated and others must be excluded. Active uptake of minerals by roots mainly depends on availability of oxygen. Some of these are discussed below:

Carrier concept: This concept was proposed by Van den Honert (1937). The space in a cell or tissue where mineral ions enter by the usage of metabolic energy is called inner space. According to this concept there are separate carriers for cations and anions. A carrier forms an ion-carrier complex on the outer surface of the membrane. This complex breaks up and releases the ion into the inner space and this release is perhaps mediated by the enzyme phosphatase. The inactivated carrier is again activated by the enzyme kinase and in this process an ATP is used up. ATP molecule combine with carrier molecules and allow passage of substances against concentration gradient. The activated carrier again accepts new ions and the entire cycle is repeated.

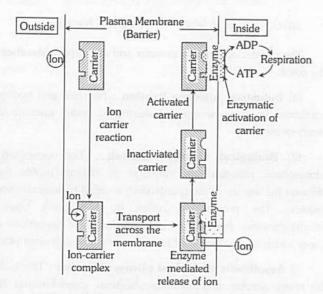

Fig: 4.2-2 The ion-carrier hypothesis

Cytochrome – pump hypothesis: This theory was proposed by Lundegardh (1950, 1954). According to this explanation only anions are absorbed actively, i.e., anion uptake requires energy and the absorption of cations does not require energy, (i.e., they are absorbed passively). At the outer surface of the membrane, the cytochrome undergoes oxidation and loses one electron and in exchange picks up an anion. This is then transported to the inner side of the membrane through to the cytochrome chain and on the inner surface of the membrane the anion is released and the cytochrome gets reduced by the action of dehydrogenase involved in respiration.

The cations move passively along the electrical gradient created by the accumulation of anions at the inner surface of the membrane.

The evidence in favour of Lundegardh's hypothesis is that the respiration increases when a plant is transferred from water to salt solution. The increased respiration is called salt respiration or anion respiration.

Criticism

- (i) It is applicable to absorption of anions only.
- (ii) It fails to explain selective absorption of ions.
- (iii) It has been observed that even cations can stimulate respiration.
 - (iv) ETS is poorly developed in anaerobically respiring forms.

Protein-lecithin carrier concept: Bennet-Clark (1956)

proposed that the carrier could be some amphoteric molecule which can carry anions as well as cations. He suggested it to be a membrane-bound protein which is conjugated with a phosphatide called as lecithin. Lecithin functions as a carrier. According to this theory, the phosphate group in the phosphatide acts as the cation binding site and choline acts as the anion binding site. During transport, ions are picked up by lecithin to form an ion-lecithin-complex. The ions are released on the inner surface of the membrane due to hydrolysis of lecithin by the enzyme lecithinase into phosphatidic acid and choline.

Lecithin is resynthesised from these components in the presence of enzyme choline acetylase and choline esterase which requires ATP.

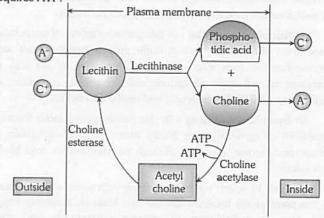

Fig: 4.2-3 The protein-lecithin carrier concept

Goldacre, 1952 proposed a mechanism of ion transport where contractile proteins act as ion carrier. They bind ions in unfolded condition on the outer face of the membrane and then contract releasing the ion into the cell and again become unfolded. The energy for this folding and unfolding is provided by ATP.

In hydrophytic plants, water and salts are absorbed by outer layer of plants.

Factors affecting mineral absorption

The process of mineral absorption is influenced by the following factors :

Temperature : The rate of absorption of salts and minerals is directly proportional to temperature.

The absorption of mineral ions is inhibited when the temperature has reached its maximum limit, perhaps due to denaturation of enzymes.

Light: When there is sufficient light, more photosynthesis occurs. As a result more food energy becomes available and salt uptake increases.

Oxygen: A deficiency of O_2 always causes a corresponding decrease in the rate of mineral absorption. It is probably due to unavailability of ATP. The increased oxygen tension helps in increased uptake of salts.

pH: It affects the rate of mineral absorption by regulating the availability of ions in the medium. At normal physiological pH monovalent ions are absorbed more rapidly whereas alkaline pH favours the absorption of bivalent and trivalent ions.

Interaction with other minerals: The absorption of one type of ions is affected by other type. The absorption of K^+ is affected by Ca^{++} , Mg^{++} and other polyvalent ions. It is probably due to competition for binding sites on the carrier. However, the uptake of K^+ and Br^- becomes possible in presence of Ca^{++} ions. There is mutual competition in the absorption of K, Rb and Cs ions.

Growth: Due to proper development surface area, no. of cells and no. of binding sites for mineral ions are increased. From that mineral absorption is also increased.

Mineral translocation

- P.R. Stout and D.R. Hoagland (1939) proved that mineral salts are translocated through xylem. After absorption of minerals by root, ions are able to reach xylem by two pathways.
- (1) Apoplast pathway: In this pathway inflow of water takes place from the cell to cell through spaces between cell wall polysaccharides. Ions thus are able to move from cell wall of epidermis to cell walls of various cells in cortex, cytoplasm of endodermis, cell wall of pericycle and finally into xylem.
- (2) Symplast pathway: In this pathway ions move through cytoplasm of epidermis and finally move through cytoplasm of cortex, endodermis, pericycle through plasmodesmata and finally into xylem.

Minerals in xylem are carried along with water to other parts of the plant along transpiration stream. Minerals reaching leaves take part in assimilation of organic compounds and then transported to other parts of the plant through phloem.

Nitrogen nutrition in plants

Higher plants generally utilize the oxidized forms such as nitrate (NO_3^-) and nitrite (NO_2^-) or the reduced form (NH_4^+) of nitrogen which is made available by a variety of nitrogen fixers. Nitrogen can be fixed by three methods :

Process of Nitrogen fixation

On the basis of agency through which the nitrogen is fixed the process is divided into two types abiological and biological.

- (1) Abiological: They are two types:
- (i) **Natural or Atmospheric nitrogen fixation:** By photochemical and electrochemical reactions, oxygen combines with nitrogen to form oxides of nitrogen. Now they get dissolved in water and combine with other salts to produce nitrates.

Physical nitrogen fixation out of total nitrogen fixed by natural agencies approximately 10% of this occurs due to physical processes such as lightening (i.e., electric discharge), thunder storms and atmospheric pollution.

Due to lightening and thundering of clouds, N_2 and O_2 of the air react to form nitric oxide (NO). The nitric oxide is further oxidised with the help of O_2 to form nitrogen dioxide (NO₂).

$$N_2 + O_2 \xrightarrow{\text{Lightening}} 2NO$$

$$2NO + O_2 \xrightarrow{Oxidation} 2NO_2$$

 NO_2 combines with H_2O to form nitrous acid (HNO_2) and nitric acid (HNO_3). The acid falls along with rain water. Now it acts with alkaline radicals to form water soluble NO_3^- (nitrates) and NO_2^- (nitrites).

$$2NO_2 + H_2O \longrightarrow HNO_2 + HNO_3$$

$$HNO_3 + Ca$$
 or K salts \longrightarrow Ca or K Nitrates

The nitrates are soluble in water and are directly absorbed by the plants.

- (ii) Industrial nitrogen fixation: Nitrogen and hydrogen combines to form ammonia industrially, under pressure and temperature.
- (2) **Biological nitrogen fixation**: The conversion of atmospheric nitrogen into inorganic or organic usable forms through the agency of living organisms is called biological nitrogen fixation. The process is carried by two main types of microorganisms, those which are "free living" or asymbiotic and those which live in close symbiotic association of with other plants.
- (i) Asymbiotic biological nitrogen fixation: This is done by many aerobic and anaerobic bacteria, cyanobacteria (blue green algae) and some fungi e.g.:

UNIVERSAL BOOK DEPOT 1960

Free living bacteria: Free living N_2 fixing bacteria add 10–25 kg of nitrogen /ha/annum.

Aerobic	-	Azotobacter
Anerobic	_	Clostridium
Photosynthetic		Chlorobium
Chemosynthetic	-	Thiobacillis

Cyanobacteria (blue-green algae) e.g., Anabaena, Nostoc, Tolypothrix cylindrospermum, Calotherix and Aulosira etc. They add 20-30~kg of N_2 per hactare of soil and water bodies.

Free living fungi e.g., Yeast cells and Pullularia.

(ii) **Symbiotic biological nitrogen fixation:** Symbiotic bacteria are found in the root nodules of the members of family Leguminosae. The best known nitrogen fixing symbiotic bacterium is *Rhizobium leguminosarum* (*Bacillus radicicola*).

Rhizobium penetrates to the cortex of root through infection thread. Simultaneously cortical cells or root are stimulated to divide more vigorously to form nodules on the root. Neither bacterium nor plant alone can fix nitrogen in such cases. Nitrogen fixation is actually the outcome of symbiotic relationship between the two. When a section of root nodules is observed the presence of a pigment, leghaemoglobin is seen to impart pinkish colour to it. This pigment is closely related to haemoglobin and helpful in creating optimal condition for nitrogen fixation. Like haemoglobin, leghaemoglobin is an oxygen scavenger. Fixation of nitrogen is done with the help of enzyme nitrogenase, which functions under anaerobic conditions. Leghaemoglobin combines with oxygen and protects nitrogenase.

Symbiotic bacteria (Frankia) have also been found to occur in root nodules of non-leguminous plants e.g., Casuarina, Cycas, Alnus, etc. Leaf nodules develop in some members of family Rubiaceae, the bacteria being Mycobacterium. Some cyanobacteria also have symbiotic association with plants e.g., Lichens; Anthoceros (a liverwort) and Azolla (a water fern).

Mechanism of biological nitrogen fixation: Several schemes incorporating such idea have been proposed and Burris (1966) accepts that the total reduction of nitrogen occurs on an enzyme complex (Nitrogenase) without release of intermediates less reduced than ammonia.

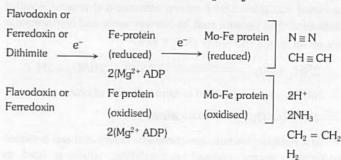

The enzyme complex nitrogenase consists of two sub-units

- (i) A non-heme iron protein commonly called Fe protein (or dinitrogen reductase, component I).
- (ii) An iron molybdenum protein called MoFe protein (or dinitrogenase, component II).

According to Burris (1966) hypothesis for nitrogen fixation suggesting the function of ATP and ferredoxin at each step in the reduction of nitrogen. The pretty function of ATP donor is furnished by pyruvate which also acts as electron donor for N_2 reduction as well.

Pyruvate on one hand acts as ATP donor while on other hand it supplies hydrogen ions and electrons for nitrogen reduction via $NADH_2$ and ferredoxin. The nitrogenase enzyme require 16 ATP molecules, 8 hydrogen ions and 8 electrons to reduce one molecule of nitrogen to $2NH_3$ molecules.

$$N_2 + 8e^- + 8H^+ + 16ATP \rightarrow 2NH_3 + H_2^+ + 16ADP + 16Pi$$

Explaining the mechanism of nitrogenase activity, its now believed that electrons are transferred from the reducing agent (Ferredoxin, Flavoprotein or Dithionite) to complex of Mg-ATP and Fe-protein (component II). From here electrons flow to Mo-Fe protein (component I) and then to substrate (nitrogen) which is finally reduced (to NH₃).

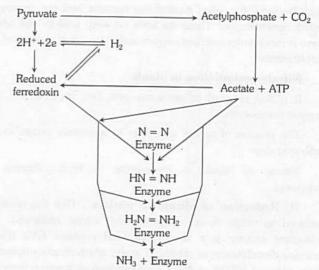

Fig: 4.2-4 Scheme suggesting the role of ATP and ferredoxin at each step in the reduction of nitrogen.
Enzymes is nitrogenase (Burris, 1966)

The ammonia formed in biological nitrogen fixation is not liberated. It is highly toxic and is immediately converted into amino acids.

Ammonia + α -ketoglutarate + NADH $\xrightarrow{\text{Dehydrogenase}}$ Glutamate + NAD+ + H_2 O.

The amino acids are transported through phloem to other parts of the plant.

Ammonification and nitrification

The free living nonsymbiotic nitrogen fixing organisms do not enrich the soil immediately. It is only after organism death that the fixed nitrogen enters the cyclic pool by the two steps namely the ammonification and nitrification.

Ammonification: The nitrogenous organic compounds in the dead bodies of plants and animals are converted into ammonia or ammonium ions in the soil. This is carried out by ammonifying bacteria. Ammonia is toxic to the plants but ammonium ions can be safely absorbed by the higher plants.

Nitrification : Once ammonia has been produced it is converted into nitrates by nitrifying activities and process is called nitrification. Soil bacteria such as *Nitrosomonas* and *Nitrosococcus* convert ammonia into nitrite (NO_2^-) ions.

$$2NH_3 + 3O_2 \xrightarrow{Nitrosomonas \text{ and } Nitrosococcus} 2HNO_2 + 2H_2O$$

Nitrites are then oxidised to nitrates by Nitrobacter.

The nitrifying bacteria are chemoautotrophs and are benefited by utilising energy released in oxidation, which is used in chemosynthesis. At soil temperatures $30^{\circ}C-35^{\circ}C$ in alkaline soils and with sufficient moisture and aeration, the activity of ammonifying and nitrifying bacteria is found to be maximum.

Some bacteria such as *Thiobacillus denitrificans* and *Micrococcus denitrificans* also occur in the soil which convert the nitrate and ammonia into atmospheric free elemental nitrogen. Such bacteria are called denitrifying bacteria and the process is called denitrification. These bacteria act very well in soil where there is more water and less oxygen and there are high level of the carbohydrate.

Nitrate assimilation in plants

It is first reduced to ammonia and then incorporated into organic compounds.

The process of nitrate reduction to ammonia occurs in the following steps :

Nitrate \rightarrow Nitrite \rightarrow Hyponitrite \rightarrow Hydroxylamine \rightarrow Ammonia

(1) Reduction of nitrate to nitrites: First the nitrate is reduced to nitrite by an enzyme called nitrate reductase. The reductase enzyme is a flavoprotein and contains FAD (Flavin adenine dinucleotide) as prosthetic group which receives hydrogen from reduced NADP or NAD. Molybdenum in enzyme serves as electron carrier.

$$NO_3 + NADPH + H^+ \xrightarrow{\text{Nitrate reductase}} NO_2^- + H_2O + NADP^+$$

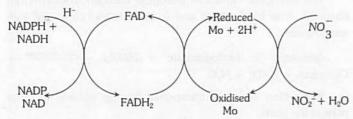

Fig: 4.2-5 Steps for nitrate reduction

(2) **Reduction of nitrites:** The nitrite ions are reduced to ammonia by an enzyme called nitrite reductase. This change occurs in leaves in the presence of light more rapidly and in dark with lesser speed. This is due to the reducing power of reaction from photochemical splitting of water.

$$2HNO_2 + 2H_2O \rightarrow 2NH_3 + 3O_2$$

Nitrite reductase does not need molybdenum but may require the presence of iron and copper. NADH and NADPH act as hydrogen donors. Application of fertilizers: Most of the soil usually contain sufficient amounts of essential mineral elements for the better crop production. Some of them are, however, deficient in certain elements. These elements are required to be supplemented externally by adding the appropriate fertilizers. Moreover, constant agricultural cultivation in field may also cause depletion of certain elements which must be replenished in order to improve the fertility of soil. The important elements need to be replenished in crop fields are nitrogen, phosphorus and potassium. These are grouped as nitrogenous fertilizers, phosphate fertilizers and potash fertilizers. These are abbreviated as NPK. Common sources of NPK are ammonium chloride, ammonium sulphate, ammonium nitrate, bone meal, calcium magnesium phosphate and nitrate of soda.

Special modes of nutrition

The method of taking in and synthesis of various types of foods by different plants and animals is called nutrition.

Generally plants are autotrophic in their mode of nutrition, but there are some examples which are heterotrophic in their mode of nutrition. These plants are unable to manufacture their own food due to lack of chlorophyll or some other reasons.

(1) Parasites: These plants obtain either their organic food prepared by other organisms or depend upon other plants only for water and minerals with the help of which they can synthesize their own food. The living organism from which the parasite obtains its organic food or water and minerals is called host. Any part of the body of parasite is modified into a special organ called haustorium which enters into the cells of host and absorbs food or water and minerals from the host.

Parasites can be classified into two categories :

- (i) Total parasites. (ii) Semiparasites or partial parasites.
- (i) Total parasites: These plants never possess chlorophyll, hence they always obtain their food from the host. They may be attached to branches, stem (stem parasites) or roots (root parasites) of the host plants.

Total stem parasite: *Cuscuta* is a rootless, yellow coloured, slender stem with small scale leaves, which twines around the host. The parasite develops haustoria (Small adventitious sucking roots) which enter the host plant forming contact with xylem and phloem of the host. It absorbs prepared food, water and minerals from the host plant.

Total root parasite: Total root parasites are common in the families like Orobanchaceae, Rafflesiaceae, Balanophoraceae, etc. *Orobanche, Rafflesia* and *Balanophora* are some of the common root parasites.

Orobanche is commonly known as broom rape. It has scale leaves and pinkish or bluish flowers. The tip of the root of parasite makes haustorial contact with the root of host and absorbs food from the host. Orobanche is usually parasitic upon brinjal, tobacco. In Rafflesia (stinking corpse lily) another root parasite, vegetative parts of the plant are highly reduced and represented by cellular filaments resembling fungal mycelium. These filaments get embedded in the soft tissue of the host while the flowers emerge out in the forms of buds.

UNIVERSAL BOOK DEPOT 1960

Balanophora occurs as a total root parasite in the roots of forest trees.

(ii) **Semiparasite or partial parasite**: Such parasitic plants have chlorophyll and, therefore, synthesize their organic food themselves. But they fulfil their mineral and water requirements from their host plants. These are of two types:

Partial stem parasites: The well known example of partial stem parasite is *Viscum album* (mistletoe) which parasitizes a number of shrubs and trees. The mature plant of *Viscum* is dichotomously branched with green leaves born in pairs attached on each node of stem. The shoots are attached to the host by means of haustoria. The primary haustoria reaches upto cortex of the host which runs longitudinally. It sends secondary haustoria which make connection with the xylem of the host and absorb water and minerals, *Loranthus* is another partial stem parasite.

Partial root parasites: The common example of partial (semi-parasite) root parasite is Santalum album (Sandal wood tree) which is an evergreen partial root parasite which grows in South India. It grows on the roots of Dalbergia sisso, Eucalyptus. Like other partial parasites, it also has green leaves and absorbs only minerals and water from the host plants.

Similarly, Striga on roots of sugarcane and Thesium on the roots of grasses are other partial root parasites.

(2) **Saprophyte**: These plants live upon dead organic matter and are responsible for conversion of complex organic substances into simple inorganic substances (minerals), e.g., some bacteria, some fungi (Yeast, Mucors, Penicillium, Agaricus), few algae (Polytoma), few bryophytes (Buxbaumia, Hypnum and Splanchnum), few pteridophytes (like Botrychium) and some angiosperms (Monotropa and Neottia) also.

Monotropa, commonly known as Indian pipe, lacks chlorophyll and is colourless or ivory white. It is found in Khasi hills and in the dense forests of Shimla. Monotropa, though usually referred to as a saprophyte, actually gets its nourishment from fungal mycelium which surround its roots. Such association between roots of higher plants and fungi is known as mycorrhiza. Neottia (Bird's nest orchid) grows in the humus rich soil of the forests. It has very few reduced leaves and thick pale yellow stem. The roots lack root hairs and the nutrients are absorbed by mycorrhiza.

(3) **Symbiotic plant :** Sometimes two different species of organisms spend much or all of their lives in close physical association, deriving mutual benefit. Such an association is known as symbiosis and each organism is known as symbiont. Symbiotic association is so close that symbionts appear to be different parts of the same plant.

Symbiotic association may be between two higher plants or between a higher plant and a lower plant. Some common examples of symbiosis are described below.

Lichens: Lichens is a special group of plants, when an alga and fungus live together and are mutually benefitted (alga provides food and fungus provides water minerals and protection of alga).

The fungus component of the lichens, called mycobiont, is generally a member of Ascomycetae or occasionally a Basidiomycetae. The algal component of the lichen is known as phycobiont and is generally a member of Chlorophyceae (e.g., Trebouxia) or Cyanophyceae (e.g., Nostoc, Gloeocapsa).

Mycorrhiza: It is a mutually beneficial association between a fungus and the root of higher plant. In such association the fungal mycelium forms a mantle over the root surface and some of the hyphae penetrate between cortical cells and metabolites are transferred in both directions (i.e., from fungus to the root cells and vice-versa).

Root nodules of leguminosae: Members of the sub-family Papilionaceae of the Leguminosae (e.g., pea, beans, trifolium) harbour species of *Rhizobium*, a nitrogen fixing bacteria. The bacteria form nodules in the roots. They fix elemental nitrogen of the atmosphere and make it available to the plant in forms that can be utilized. In turn they derive food and shelter from the leguminous plant.

Myrmecophily: It is the symbiotic relationship between ants and some higher plants. The ants obtain food and shelter from the plant. They protect the plant (e.g., Mango) from other animals. In Acacia sphaerocephala the stipules are hollowed to function as ant shelter. Leaflet tips (Belt's corpuscles) and rachis (extrafloral nectaries) possess feeding materials. A higher plant which is benefitted by association with ants is called myrmecophyte. The term myrmecophily is also used for pollination by ants.

(4) Carnivorous or Insectivorous plants: These plants are autotrophic in their mode of nutrition but they grow in marshy or muddy soils, which are generally deficient in nitrogen and in order to fulfil their nitrogen requirement, these plants catch small insects. The organs and specially leaves of these plants are modified variously to catch the insects. These plants have glands secreting proteolytic enzymes which breakdown complex proteins into simple nitrogenous substances, which inturn are absorbed by these plants. Some of these plants are as follows:

Drosera (Sundew): It is a herbaceous plant having spathulate or lunate leaves. The leaves are covered by glandular hair with a swollen tip. The glands secretes a sticky purple juice which shines like a dew drop in bright light sunshine, hence the name sundew. These long special hair are generally referred to as 'tentacles'. When an insect alights on the leaf, the tentacles curve due to thigmonasty. The insect is killed and its proteins are digested by pepsin hydrochloride. Similar tentacles are also found in *Drosophyllum*.

Utricularia (**Bladderwort**): It is submerged floating aquatic herb which lacks roots. Some of the species of *Utricularia* also occur in moist soil. The leaves are dissected into fine segments and appear like roots. Some of the leaf segments are modified into pear-shaped sacs called bladders or utricles.

The bladders are triangular or semicircular structures having a single opening guarded by a valve. There are numerous bristles near the mouth and digestive glands inside. The bladders show special trap mechanism. The valve of the bladder opens on the inner side. When small aquatic animalcules enter the bladder along with water current, they get trapped inside. Their proteins are digested enzymatically. When a bladder is full of undigested matter, it degenerasis.

Nepenthes (Pitcher plant): They are commonly found in tropical areas like Assam and Meghalaya (i.e., N. Khasiana). It is an endangered species. In this plant the leaf base is winged, petiole is tendrillar and the lamina is modified into pitcher. The pitcher has a distinct collar at the mouth and the apex is modified into the lid. The undersurface of the lid has alluring glands whereas the inner surface of pitcher is lined by numerous digestive glands and several downward directed hair. The lid attracts insects which slide down into the pitcher. The downward directed hair check their escape. The insect is killed and its proteins are digested by pepsin hydrochloride. Other insectivorous plants having leaf pitchers are Sarracenia, Cephalotus, Heliamphora, etc.

Dionaea (Venus fly trap): It is a small herbaceous plant found mainly in America. The plant has a rosette of radiating leaves. The petiole is winged and photosynthetic. The lamina is bilobed and the midrib acts like a hinge between the two lobes of the lamina. Each lobe has 15-20 trigger hairs or bristles. These hairs are very sensitive to nitrogenous substances. When an insect alights on the leaf and touches the sensitive hairs, the two lobes of lamina fold along the midrib. Thus the insect is trapped in between the lobes. Pepsin hydrochloride secreted by the digestive glands, present in the upper part of the lobes digests the insect.

Sarracenia (Pitcher plant; Devil's boot): This pitcher plant is found in the temperate regions. It has a very reduced stem which bears a rosette of leaves. The leaves are modified into pitchers. It can easily be distinguished from Nepenthes on the basis of its trumpet-shaped sessile pitchers. The pitchers of Sarracenia lack digestive enzymes and here the insects are decomposed by bacteria.

Pinguicula (Butterwort): It is a herbaceous plant having a basal rosette of ovate leaves. The leaf margins are slightly curved in upward direction. The dorsal (upper) surface of leaf has two types of glands stalked and sessile. The stalked glands secrete mucilage while the sessile glands secrete digestive enzymes.

Aldrovanda (Water flea trap): It is also a rootless, submerged aquatic plant (bog plant) recalling the habit of *Utricularia*. The leaves are bilobed with long petioles. There are five bristle like outgrowths associated with the lamina. The leaf surface is covered by visid stalked glands. The proteins of the insect are digested enzymatically.

Tips & Tricks

- Ø De Saussure (1804) first of all demonstrated that plants obtain minerals from soil through root system.
- ∠ Liebig for the first time discovered the presence of elements in plant ash.
- \mathcal{E} Tracer elements: These are radioactive isotopes of elements, which are used to detect various metabolic pathways in plants, e.g., C^{14} , N^{15} , P^{32} , S^{35} , etc.).

- Hydroponics developed by Geriche.
- Venedium (V) is required by alga Scenedesmus.
- Selenium (Se) is required by Atriplex and Astragalus.
- Iodine is required by marine alga Polysiphonia.
- Critical elements are the elements in which soil is generally deficient e.g., N, P and K. These are given in form of fertilizers.
- Silica: Found in grasses and diatoms.
- Sodium : Found in halophytes.
- S Cobalt: Found in ferns (e.g., Lycopodium) taking part in growth.
- Nickel: Enzyme urease uses it to hydrolyse urea by living organisms.
- Dischidia is the pitcher plant, which is without lid and it is used only for storing rain water.

- Cytozyme is a water soluble commercial preparation which contains essential mineral element for use as foliar spray.
- Cytochromes act as anion carriers.
- Phytotron is the place or laboratory where plants can be maintained and studied under wide range of controlled conditions.
- Rafflessia (largest flower in the world) was discovered by Sir Stamford Raffles from Java. Flower measures about a meter in diameter, about 11 kg in weight, smell is like rotten fish, pollination by elephants and found on roots of Vitis and Cissus.
- \varnothing Sapria himalayensis (largest flower in India), measures 15 cm 30 cm in diameter.
- Cephalotus (Fly Catcher). A deep rooted carnivorous herb with a rosette of pitchers for trapping small animals.
- Bird of paradise flower is Sterilitzia reginae.
- Arceuthobium is the smallest dic of angiospermic parasite. It is total parasite that grows on a number of forest trees including Pinus and Juniper.

Ordinary Thinking

Objective Questions

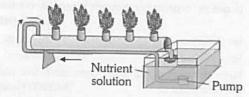

General

 Which one of the following is not an essential mineral element for plants while the remaining three are

[NCERT; MP PMT 1992; CBSE PMT (Mains) 2011]

- (a) Cadmium
- (b) Phosphorus
- (c) Iron
- (d) Manganese
- In plant nutrition elements are classified as major or minor depending on
 - (a) Their availability in the soil
 - (b) Their relative production in the ash obtained after burning the plants
 - (c) The relative amounts required by the plants
 - (d) Their relative importance in plant growth
- The given figure shows hydrophonic / soil less plant production. Plants are grown in a tube or through placed on a slight incline. The arrows indicate the direction of flow of nutrient solution.

Nutrient solution is sent to the elevated end of the tube from the reservoir by _____ and it flows back into reservoir due to _____ [NCERT]

- (a) Pump, Gravity
- (b) Gravity, Pump
- (c) Gravity, Gravity
- (d) Pump, Pump
- 4. Inorganic nutrients are present in the soil in the form of

[MP PMT 1999; BHU 2008]

- (a) Molecules
- (b) Atoms
- (c) Electrically charged ions (d) Parasite
- Sulphur is an important nutrient for optimum growth and productivity in [CBSE PMT 2006]
 - (a) Fibre crops
- (b) Oilseed crops
- (c) Pulse crops
- (d) Cereals
- An essential element is one

[NCERT]

- (a) Improve plant growth
 - (b) Present in plant ash
- (c) Is indispensable for growth and is irreplaceable
- (d) Available in soil
- Hydroponics are [NCERT; MP PMT 1992; KCET 1994;
 EAMCET 1995; CPMT 1998; Pb. PMT 1999;
 KCET 1999; AMU (Med.) 2005]
 - (a) Growing of aquatic plants
 - (b) Growing of floating aquatic plants
 - (c) Growing of plants in sand
 - (d) Growing of plants aqueous balanced nutrient

8. Which of the following ions of heavy metals participate in process of photosynthesis in higher plants

[AMU (Med.) 2005]

[MP PMT 2002]

- (a) Pb, Fe, Ni, Co
- (b) Mg, Zn, Cu, Hg
- (c) Mg, Mn, Co, Fe
- (d) Mg, Cu, Mn, Fe
- 9. Necrosis means
 - (a) Yellow spots on the leaves
 - (b) Death of tissue and decomposition
 - (c) Darkening of green colour in leaves
 - (d) None of the above
- 10. Tracer elements are

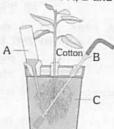

ridcer elements are

(b) Macro-elements

- (a) Micro elements
- (1) 110
- (c) Radio isotopes
- (d) Vitamins
- 11. Essential elements for plants are[MP PMT 2005; KCET 2007]
 - (a) Life cycle incomplete without it
 - (b) Non replaceable
 - (c) Metabolism (necessary for it)
 - (d) All above
- 12. In hydrophytic plants, water and salts are absorbed by

[MP PMT 1992]

- (a) Roots
- (b) Leaves
- (c) Stem
- (d) Outer layer of plants
- 13. The given figure shows a typical setup for hydrophonic technique. Choose the option which gives correct set of words for all the three blanks A, B and C [NCERT]

- (a) A Funnel for adding water and nutrients, B Aerating tube, C Water
- (b) A Funnel for adding nutrients only, B Aerating tube, C Nutrient solution
- (c) A Funnel for adding water only, B Aerating tube, C Nutrient solution
- (d) A Funnel for adding water and nutrients, B Aerating tube, C Nutrient solution
- The number of essential elements required for normal growth of plant is [BHU 2003]
 - (a) 10
- (b) 16
- (c) 20

- (d) 25
- 15. Aeroponic is also called as
 - (a) Soilless cultivation of plants
 - (b) Parthenocarpy
 - (c) Vivipary
 - (d) Phytotron
- 16. Who gave the criteria of essentiality
 - (a) R. Hill
- (b) F.F. Blackman
- (c) M.P. Kaushik
- (d) D.L. Arnon

UNIVER BOOK D	640 Mineral Nutrition		
17.	Which one of the following scientists used the nutrient culture solution in hydroponic cultures [MP PMT 1995]	7.	Interveinal chlorosis of leaves is caused by the deficiency of [Kashmir MEE 1995]
	(a) Sachs (b) Webster		(a) Nitrogen (b) Calcium
	(c) Wallace (d) Knop		(c) Potassium (d) Magnesium
18.	Which group of element is not essential for a normal plant [CBSE PMT 1996; AFMC 2009]	8.	Chlorosis occurs when plants are grown in
	(a) Potassium, calcium, magnesium		(a) Dark

Micro-Nutrients

A trace element is an element which

[NCERT]

- (a) Is a radioactive and can be traced by Geiger counter
- (b) Is required in very minute amounts
- (c) Draws other element out of protoplasm
- (d) Was one of the first to be discovered in protoplasm
- 2 Micro-nutrients are

[CPMT 2002]

- (a) Less important in nutrition than macro-nutrients
- (b) As important in nutrition as macro-nutrients
- (c) May be omitted from culture media without any detrimental effect on the plant
- (d) Called micro because they play only minor role in nutrition
- 3. Deficiency of molybdenum cause
 - (a) Poor development of vasculature
 - (b) Bending of leaf tip
 - (c) Yellowing of leaves
 - (d) Mottling and necrosis of leaves
- Find out the correctly matched pair [Kerala PMT 2012]

Nutrients

Functions

- (a) Zinc Helps to maintain the ribosome structure
- (b) Magnesium Needed during the formation of mitotic spindle
- Calcium Plays a role in the opening

and closing of stomata

(d) Manganese Needed in the splitting of

> water to liberate oxygen during photosynthesis

- (e) Potassium Needed in the synthesis of auxin
- In a Citrus plantation, all the plants were found to be suffering from the die-back disease, spraying of fungicides was of no help. This problem was due to the deficiency of
- (a) Copper
- (b) Gibberellic acid
- (c) Zinc
- (d) Auxins
- Appearance of brown spots surrounded by chlorotic veins is a prominent toxicity symptom of [AMU (Med.) 2009]
 - (a) Mn
- (b) Mo
- (c) Mg
- (d) Zn
- 7. Which of the following is widely used metal cofactor

[CBSE PMT 2003]

- (a) Ca2+
- (b) Al3+
- (c) Ni2+
- (d) Mg3+
- 8. For its activity, carboxypeptidase requires

[NCERT; CBSE PMT (Mains) 2012]

Which one is the co-factor of carbonic anhydrase

[WB JEE 2010]

- (a) Zinc
- (b) Iron
- (c) Niacin
- (d) Copper

9. Apple fruit develop internal cork due to deficiency of

'Petiole crack' is caused by the deficiency of

- (a) Magnesium
- (b) Iron
- (c) Manganese
- (d) Boron
- 10. Micronutrients are needed in amounts equivalent to

[AMU (Med.) 2010]

- (a) 8m mole/kg of dry matter (b) 18m mole/kg of dry matter
- (c) 25m mole/kg of dry matter (d) 30m mole/kg of dry matter
- Mottle leaf in citrus plants is due to deficiency of

[MP PMT 1997]

Or

One of the causes of littles leaf disease is due to deficiency of [J & K CET 2008]

- (a) Boron
- (b) Magnesium
- (c) Zinc
- (d) None of these
- 12. The deficiency of molybdenum induces
 - (a) Citrus die back disease
 - (b) Pea rossete disease
 - (c) Cauliflower whip tail disease
 - (d) White bud of maize
- Boron in green plants assists in 13.

[CBSE PMT 2003]

- (a) Sugar transport
- (b) Activation of enzymes
- (c) Acting as enzyme cofactor (d) Photosynthesis
- Study the following lists

List-I	Desc.	List-II
(A) Photolysis of water	(I)	Zinc
(B) Diazotrophy	(II)	Copper
(C) Cytochrome 'c' oxidase	(III)	Manganese
(D) Biosynthesis of IAA	(IV)	Molybdenum
	(V)	Boron

			1 (+ /	DOLON	ALPCO TO A TO

 - (a) Independent of water absorption
 - (b) Dependent on water absorption
 - (c) Dependent on strength of solutions
 - (d) Dependent on osmosis
- 13. By which method ions are absorbed by plants [RPMT 1992]
 - (a) By difference in DPD
 - (b) By difference in water potential
 - (c) By carriers and pumps
 - (d) By molecular diffusion
- 14. Nobel prize of 1991 for discovering the single ion channels in cell was awarded to
 - (a) Waston and Hargobind Khorana
 - (b) Erwin Neher and Bert Stakmann
 - (c) Nirenberg and Kornberg
 - (d) Holley and Matthaei
- In the light of carrier concept, the transport of ion across the membrane is
 - (a) Passive process
- (b) Non-osmotic process
- (c) Osmotic process
- (d) Active process
- 16. If the amount of an ion absorbed by a root hair cell at 0° C is 5 gm and at 20° C is 20 gm. The amount of this ion absorbed actively should be
 - (a) 25 gm
- (b) 20 gm
- (c) 15 gm
- (d) 5 gm
- 17. Solutes are absorbed by a plant cell through
 - (a) Osmosis
- (b) Diffusion
- (c) Active absorption
- (d) Passive absorption

Nitrogen nutrition

 Most of the plants obtain or absorb nitrogen from soil in the form of [NCERT;

Odisha PMT 2002; MP PMT 2005; AFMC 2010]

- (a) Free nitrogen gas
- (b) Nitric acid
- (c) Nitrite
- (d) Nitrates and ammonium salt
- In root nodules of legumes, leg-haemoglobin is important because [NCERT; AMU (Med.) 2006; DUMET 2009]
 - (a) It transports oxygen to the root nodule
 - (b) It acts as an oxygen scavenger
 - (c) It provides energy to the nitrogen fixing bacterium
 - (d) It acts as a catalyst in trans-amination
- 3. The possibility of increase of infectious disease become more due to more supply of
 - (a) Potassium
- (b) Magnesium
- (c) Copper
- (d) Nitrogen
- 4. Cell elongation is adversely affected by

Oi

Element required by plant in large quantity is [DPMT 1992]

- (a) Sodium
- (b) Cobalt
- (c) Manganese
- (d) Nitrogen

The enzyme responsible for the reduction of molecular nitrogen to the level of ammonia in leguminous root nodule is [Kerala PMT 2009; AIIMS 2013]

Or

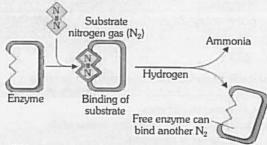

The enzyme responsible for atmospheric nitrogen fixation is [AIIMS 2000; CBSE PMT 2001]

- (a) Nitrogenase
- (b) Nitrate reductase
- (c) Nitrite reductase
- (d) Hydrogenase
- (e) Carboxylase
- An important essential element is necessary in plants for protein synthesis

Or

The most important element associated with protoplasm and proteinaceous materials of plant is [MP PMT 2010]

- (a) Calcium
- (b) Phosphorus
- (c) Magnesium
- (d) Nitrogen
- The given figure represents the Nitrogen fixation. See the diagram and select the correct option

- I. Nitrogenase catalyses the reaction
- II. The formation of ammonia is a reductive process
- III. One molecule of nitrogen produces two molecules of ammonia
- IV. Nitrate reductase catalyse the reaction
- V. Formation of ammonia is an oxidative process
- VI. One molecule of nitrogen produces one molecule of ammonia [NCERT]
- (a) III, IV and V are correct (b) I, V and VI are correct
- (c) IV, V and VI are correct (d) I, II and III are correct
- 8. Nitrogen is an important constituent of

[MP PMT 1994, 2002]

- (a) Proteins
- (b) Lipids
- (c) Carbohydrates
- (d) Polyphosphates
- Which one of the following is an amide involved in nitrogen assimilation by plants [NCERT; Kerala PMT 2009]
 - (a) Glutamate
- (b) Alanine
- (c) Asparagine
- (d) Serine
- (e) Glycine
- 10. $N_2 + 8_{e^-} + 8H^+ + 16ATP \rightarrow 2NH + H_2 + 16ADP + 16Pi$

The above equation refers to [NCERT; Kerala PMT 2007]

- (a) Ammonification
- (b) Nitrification
- (c) Nitrogen fixation
- (d) Denitrification
- (e) Reductive amination
- For its action, nitrogenase requires

[NCERT; CBSE PMT (Mains) 2012]

- (a) High input of energy
- (b) Light
- (c) Mn2+
- (d) Super oxygen radicals

			Mineral Nutrition 645	UNIVERSAL BOOK DEPOT 1960
12.	Which one of the following can fix atmospheric nitrogen directly	25.	. Higher plants obtain nitrogen from soil that has	
	(a) Pea (b) Brassica			PMT 2013
	(c) Castor (d) Petunia		(a) Six forms (NO ₃ , NO ₂ , N ₂ O ₂ , N ₂ , NH ₂ O	$H, NH_3)$ of
13.	N ₂ fixation is		nitrogen with oxidation number ranging from	
	[CPMT 1996; MHCET 2003; Odisha JEE 2005]		(b) Six forms (NO ₃ , NO ₂ , N ₂ O ₂ , N ₂ , NH ₂ O ₃ nitrogen with oxidation number ranging from the control of the contr	H, NH_3) of
	(a) $N_2 \rightarrow NH_3$ (b) $N_2 \rightarrow NO_3$		(c) Five forms (NO ₃ , NO ₂ , N ₂ , NH ₂ OH, NH ₃)	
	(c) $N_2 \rightarrow \text{Amino acid}$ (d) Both (a) and (b)		with oxidation number ranging from +5 to	-3
14.	Nodules with nitrogen fixing bacteria are present in [AFMC 2001; CPMT 2003]		(d) Five forms (NO ₃ , NO ₂ , N ₂ , NH ₂ OH, NH ₃) with oxidation number ranging from +6 to-	of nitrogen
	(a) Cotton (b) Gram	26.		
	(c) Wheat (d) Mustard			NEET 2013]

INCERTI

30. Pitcher plant is

[KCET 1998]

Or

Drosera and Sarracenia are

- (a) Herbivorous
- (b) Carnivorous
- (c) Saprotroph
- (d) All of these
- Which of the following is not an insectivorous plant

[AFMC 2004; J & K CET 2010]

- (a) Drosera
- (b) Nepenthes
- (c) Monotropa
- (d) Utricularia

Exemplar Questions

When a plant undergoes senescence, the nutrients may be

[NCERT]

- (a) Exported
- (b) Withdrawn
- (c) Translocated
- (d) None of the above
- 2. Choose the correct option mycorrhiza is a symbiotic association of fungus with root system which helps in
 - (A) Absorption of water
- (B) Mineral nutrition
- (C) Translocation Options:
- (D) Gaseous exchange [NCERT]
- (a) Only (A)
- (b) Only (B)
- (c) Both (A) and (B)
- (d) Both (B) and (C)
- 3. Which one of the following roles is not characteristic of an essential element [NCERT]
 - (a) Being a component of biomolecules
 - (b) Changing the chemistry of soil
 - (c) Being a structural component of energy related chemical compounds
 - (d) Activation or inhibition of enzymes
- Which one of the following statements can best explain the term critical concentration of an essential element [NCERT]
 - (a) Essential element concentration below which plant growth is retarded
 - (b) Essential element concentration below which plant growth becomes stunted
 - (c) Essential element concentration below which plant remains in the vegetative phase
 - (d) None of the above
- 5. Deficiency symptoms of an element tend to appear first in young leaves. It indicates that the element is relatively immobile. Which one of the following elemental deficiency would show such symptoms INCERTI
 - (a) Sulphur
- (b) Magnesium
- Nitrogen (c)
- (d) Potassium
- 6. Which one of the following symptoms is not due to manganese toxicity in plants [NCERT]
 - (a) Calcium translocation in shoot apex is inhibited
 - (b) Deficiency in both Iron and Nitrogen is induced
 - (c) Appearance of brown spot surrounded by chlorotic veins
 - (d) None of the above
- Reaction carried out by N₂ fixing microbes include
 - $2NH_3 + 3O_2 \rightarrow 2NO_2^- + 2H^+ + 2H_2O$ (i)
 - (b) $2NO_2^- + O_2 \rightarrow 2NO_3^-$

Which of the following statements about these equations is not true

- (a) Step (i) is carried out by Nitrosomonas or Nitrococcus
- (b) Step (ii) is carried out by Nitrobacter
- (c) Both steps (i) and (ii) can be called nitrification
- Bacteria carrying out these steps are usually photoautotrophs

- With regard to the Biological Nitrogen Fixation by Rhizobium in association with soyabean, which one of the following statement/statements does not hold true [NCERT]
 - (a) Nitrogenase may require oxygen for its functioning
 - (b) Nitrogenase is MO-Fe protein
 - (c) Leg-haemoglobin is a pink coloured pigment
 - (d) Nitrogenase helps to convert N2 gas into two molecules of ammonia
- 9 Match the element with its associated functions/roles and choose the correct option among given below
- i. Splitting of H2O to liberate O2 during photosynthesis
- Manganese
- ii. Needed for synthesis of auxins
- C. Molybdenum
- iii. Component of nitrogenase
- D. Zinc
- iv. Pollen germination
- Iron
- Options
- v. Component of ferredoxin
- (a) A-i. B-ii, C-iii, D-iv. F-v
- (b) A-iv, B-i, C-iii, D-ii. E-v
- (c) A-iii, B-ii, C-iv, D-v, E-i
- (d) A-ii, B-iii, C-v, D-i, E-iv
- Plants can be grown in (Tick the incorrect option) [NCERT] 10.
 - (a) Soil with essential nutrients
 - (b) Water with essential nutrients
 - (c) Either water or soil with essential nutrients
 - (d) Water or soil without essential nutrients

Critical Thinking Objective Questions

- Which of the following deficiency may cause leaf tip bending [BVP 2003]
 - (a) Sulphur
- (b) Nitrogen
- (c) Phosphorus
- (d) Calcium
- EDTA is much used in tissue cultures, it is a
 - (a) Hormone
- (b) Vitamin
- (c) Buffer
- (d) Nutrient
- Match the following and choose the correct combination from the options given

	Column I		Column II
A.	Potassium	1.	Constituent of ferredoxin
B.	Sulphur	2.	Involved in stomatal movement
C.	Molybdenum	3.	Needed in the synthesis of auxin
D.	Zinc	4.	Component of nitrogenase

[CBSE PMT 2003; Kerala PMT 2006, 10]

- (a) A-2, B-1, C-4, D-3 (b) A-1, B-2, C-3, D-4
- (c) A-4, B-3, C-2, D-1 (d) A-1, B-3, C-4, D-2
- (e) A-3, B-4, C-1, D-2

- Minerals known to be required in large amounts for plant growth include [AIPMT (Cancelled) 2015]
 - (a) Calcium, magnesium, manganese, copper
 - (b) Potassium, phosphorus, selenium, boron
 - (c) Magnesium, sulphur, iron, zinc
 - (d) Phosphorus, potassium, sulphur, calcium
- Match the following mineral element with their deficiency symptom and choose the correct option

	Column I		Column II
A.	Calcium	1.	Chlorotic veins
B.	Potassium	2.	Delayed germination of seeds
C.	Zinc	3.	Necrosis of young leaves
D.	Iron	4.	Scorched leaf tips
E.	Phosphorous	5.	Malformed leaves

[Kerala PMT 2008]

- (a) A-3, B-1, C-5, D-2, E-4
- (b) A-1, B-4, C-5, D-3, E-2
- (c) A-3, B-4, C-5, D-1, E-2
- (d) A-2, B-3, C-4, D-1, E-5
- (e) A-4, B-2, C-1, D-3, E-5
- 6. Which of the following is considered to be the best chemical method of fixing atmospheric nitrogen [BHU 2004]
 - (a) Fisher method
 - (b) Decan method
 - (c) Haber-Bosch method
 - (d) Paranas-Meyerhoff method
- 7. Fly-ash is a/an

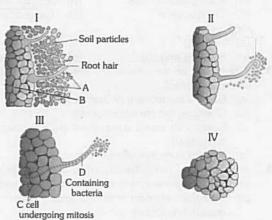

[BHU 2004]

- (a) Insectivorous plant
 - (b) Light airborne particulate matter
 - (c) New name of orchid plant
 - (d) Causal organism of various diseases
- 8. Which one of the following is correctly matched

[CBSE PMT (Pre.) 2012]

- (a) Passive transport of nutrients ATP
- (b) Apoplast Plasmodesmata
- (c) Potassium Readily immobilisation
- (d) Bakane of rice seedlings F. Skoog
- On the basis of symptoms of chlorosis in leaves, a student inferred that this was due to the deficiency of nitrogen. This inference could be correct only if yellowing of leaves appeared first in [AIIMS 2007]
 - (a) Young leaves
 - (b) Old leaves
 - (c) Young leaves followed by old leaves
 - (d) Old leaves followed by young leaves
- 10. Aldrovanda is
 - (a) Fly catcher plant
- (b) Water flea trap
- (c) Devil's foot
- (d) None of these

- Which of the following shows that metabolic energy is required in the absorption of ions
 - (a) More ions absorption in presence of oxygen
 - (b) Less absorption of ions in presence of oxygen
 - (c) More ions absorption in presence of ATP
 - (d) More ions absorption in presence of NAD
- 12. According to the well known theory of transport of solutes across a cell membrane, what happens when sugar is passed through it [CBSE PMT 1992]
 - (a) Na⁺ flows in the direction of the sugar
 - (b) Na+ flows independent of sugar molecules
 - (c) Na+ flows against the sugar molecules
 - (d) Na+ ions do not flow at all
- 13. The given figure indicates the development of root nodule in soyabean

Identify A, B, C and D respectively

[NCERT]

- (a) A Nitrosomonas bacteria; B Cortex cell; C Inner cortex; D - Infection thread
- (b) A Rhizobial bacteria; B Endodermal cell; C Inner Endodermis; D - Infection thread
- (c) A Rhizobial bacteria; B Cortex cell; C Inner cortex;
 D Infection thread
- (d) A Rhizobial bacteria; B Cortex cell; C Outer cortex;
 D Infection thread
- 14. The smallest angiospermic/dicot parasite is [JIPMER 1997]
 - (a) Arceuthobium
- (b) Wolffia
- (c) Cassytha
- (d) Rafflesia
- 15. Fertility of the soil in rice fields can be improved by

[MP PMT 1992]

- (a) Gypsum
- (b) Sodium chloride
- (c) Blue-green algae
- (d) Rhizobium

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- If both the assertion and the reason are true and the reason (a) is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- If the assertion is true but the reason is false (c)
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- Assertion 1. Plants lack excretory organs.
 - Reason
 - Plant usually absorb essential nutrients and lead a passive life. [AIIMS 1997]
- 2. Assertion Leguminous plants are nitrogen fixers.
 - Reason Leguminous plants have Rhizobium in their
- root nodules. [AIIMS 1997]
- 3. Insectivorous habitat of plants is to cope up Assertion O2 deficiency.
 - Reason Insectivorous plants are partly autotrophic and partly heterotrophic. [AIIMS 1998]
- 4. Assertion Use of fertilizers greatly enhances crop productivity.
 - Irrigation is very important in increasing Reason
- crop productivity. [AIIMS 2003] Assertion 5. Hydroponics is used for solution culture.
 - Reason A balanced nutrient solution contains both essential and nonessential elements.
- 6 Assertion The leaves of cauliflower become flaccid and brown in molybdenum deficiency.
 - Reason Cauliflower plant is affected by whiptail
- disease in molybdenum deficiency. 7. Assertion In Dionaea, each lamina has marginal teeth.
- Reason Marginal teeth of Dionaea help in prey capturing.
- 8. Assertion Plants absorb nitrogen in the form of nitrate only.
 - Reason Nitrogen is the most critical element.
- 9 Assertion Magnesium is important in photosynthesis and carbohydrate metabolism.
 - Reason Mg++ is involved in the synthesis of nucleic
- 10. Assertion Manganese is an activator of enzyme nitrite reductase.
 - Reason Manganese deficient cells prefer ammonia over nitrate.
- Nitrogen-fixing bacteria in legume root 11. Assertion nodules survive in oxygen-depleted cells of
 - nodules. Reason Leghaemoglobin completely removes
- oxygen from the nodule cells. [AIIMS 2004] 12 Assertion Deficiency of sulphur causes chlorosis in

plants.

Reason Sulphur is a constituent of chlorophyll, proteins and nucleic acids. [AIIMS 2004]

- 13 Assertion Exanthema disease occurs due deficiency of manganese.
 - Reason Reclamation is a disease of cereals.
- 14 Assertion Iron is a microelement.
 - Reason Microelements are required in traces only,
 - less than 1mg/gm of dry matter. Assertion
 - In solution culture of plants, iron is added in the form of Fe-EDTA.
 - Reason Hydroponics set-up is costly.

Answers and Solutions

General

- 2. (c) Major elements are required by plants in quantity of more than 1 milligram/gram dry matter and minor elements are required in quantity of less than 1 milligram/gram of dry matter.
- 6. (c) An essential element is the one which has a specific structural or physiological role and without which plants cannot complete their life cycle.

- (d) Soilless production of plants is called hydroponics. A solution having all the essential elements in proper proportion is called normal or balanced nutrient solution.
- (b) Necrosis is death of cells of an area which therefore, becomes discoloured.
- (c) Tracer elements are radioactive isotopes of elements, which are used to detect various metabolic pathways in plants e.g., C¹⁴, N¹⁵, P³², S³⁵ etc.
- 15. (a) Aeroponic plants are grown with their roots bathed in nutrient mist. This method has been successfully used in growing Citrus and olive plants.
- **16.** (d) Criteria for essentiality of elements were first of all given by Arnon.
- (d) The nutrient solution composition proposed by Knop (1865) and Arnon and Hoagland's (1940) are commonly used.
- 20. (c) Etiolation is a type of growth exhibited by plants grown in darkness, usually in seed. They lack chlorophyll and therefore appears white or yellow.
- 21. (a) Sand culture plants are grown in inert sand + nutrient solution. Main advantage is that roots get natural environment and proper aeration.

Macro-Nutrients

- 2. (b) Mg is present in centre of chlorophyll molecule head.
- 3. (c) N and K are mobile elements.
- 5. (b) Mg is an important constituent of chlorophyll molecule where it occupies a central position and essential for photosynthesis and Fe plays an important role in ETS, photosynthesis and respiration because iron is the part of cytochromes. It is also essential for chlorophyll synthesis.
- 6. (d) According to Webster (1953) potassium is activator of more than 40 enzymes connected with phosphorylation, photosynthesis, starch synthesis, respiration, synthesis of chlorophyll, DNA and proteins.
- 7. (d) Mg is chief element of chlorophyll molecule.
- (a) Magnesium is a component of porphyrin part of chlorophyll molecule.
- 10. (b) Phosphorus is absorbed by the plants from the soil in the form of phosphate ions H₂PO₄⁻ and HPO₄²⁻ and nitrogen is absorbed by the plants in the form of nitrate ions (NO₃⁻).
- (d) Nitrogen, phosphorus and potassium are three critical elements which are essential for proper growth of plants e.g., crop plants.
- (a) Natural organic compounds are generally made up of carbon, hydrogen and oxygen.

- 14. (a) Boron has some role in the osmoregulation during the in vitro pollen fermination. Boron is responsible for maintaining the solubility of calcium in cells.
- 15. (c) The foliage leaves are the first to suffer from its deficiency. Their tips become scorched and margins become dull yellow in colour.
- 16. (c) Carbon is absorbed in the form of carbon dioxide.
- 17. (a) Carbon, hydrogen and oxygen together constitute about 94% of the total dry weight of the plant. Frame work elements: C, H, N, O, P, S; these six elements are called as frame work elements which constitute the body of plants.
- 18. (c) Fertilizers providing N, P, K and minerals is called complete fertilizer. Nitrogen is necessary for dividing tissues, phosphorus is required for development of young tissue, growth of them, potassium is required in meristematic tissue, growing tips, leaves etc. The deficiency of N, P, K cause yellowing of leaves and premature death.
- 21. (b) Potassium is the commonest free in the cell and help to keep the cell electrically neutral and perphaps stabilises emulsions.
- 22. (a) Phosphorus plays an indispensable role in energy metabolism i.e., hydrolysis of pyrophosphate and various organic phosphate bonds being used to drive chemical reactions. Thus it is required for all phosphorylation reactions.
- (c) Sulphur is relatively immobile and therefore, deficiency symptoms appear first in young leaves.
- 24. (c) In plant ash, nitrogen is not present because it releases out as its oxide when heated upto 600° C to obtain plant ash, however it is an essential element.
- 25. (b) Phosphorus is absorbed by the plants from the soil in the form of phosphate ions H₂PO₄⁻ and HPO₄²⁻.
- 26. (a) Mo, Mn and Zn are microelements.
- 27. (d) Calcium is essential for fat metabolism, carbohydrate metabolism, nitrate assimilation and binding of nucleic acid with proteins.
- 28. (c) Magnesium occurs in the soil in the form of magnesite (MgCO₃), dolomite (MgCO₃, CaCO₃), magnesium sulphate (MgSO₄) and as silicates. It is absorbed from the soil in form of ions (Mg⁺⁺).
- 30. (d) Phosphorus deficiency causes premature leaf fall and leaves become dark to blue-green in colour.
- 31. (a) Iron occurs in the concentration of less than 1 mg/gm. However, its essentiality was discovered along with other macroelements long before microelements were found to be required. Therefore, it is often regarded to be macroelement.

- 32. (a) Onion and its relatives also possess antimicrobial sulphur containing compounds allicin and diallylsulphide. Tear promoting substance is also a sulphur compound propanethial sulphenic oxide. Reduced meristematic activity and chlorotic leaves produce tea yellow disease of tea plants.
- 33. (b) Calcium stimulates development of root hairs.
- 34. (a) Meristematic regions found is stem, leaf and root tips are greatly affected by the absence of calcium because it is not rapidly translocated to these regions. Ultimately they die and thus stop the growth of these organs. Calcium involved in selective permeability of cell membranes. It activates certain enzymes required for development of stem and root apex and as calcium pectate in the middle lamella of the cell wall
- **36.** (c) Nucleotide is made up by nitrogen base + sugar (ribose or deoxyribose) + phosphate.
- 38. (a) Phosphorus promotes healthy root growth and fruit ripening by helping translocation of carbohydrates.

Micro-Nutrients

- (b) They are those essential elements which are required by plants in traces only, equal or less than 0.1 mg/gm of dry matter. They are eight in number – Fe, Zn, Mn, B, Cu, Mo, Cl and Ni.
- 2. (b) Micro-nutrients are present in less amount in plants but they are as important as macro-nutrients.
- (d) Mottled chlorosis with marginal necrosis and infolding, lamina or upper half of lamina falls down (whiptail disease) due to the deficiency of molybdenum.
- **5.** (a) Cu deficiency causes necrosis of the tip of the young leaves (e.g., Citrus). The disease is called 'die back'.
- (c) Some minerals are either components of enzymes, their cofactors or activators. e.g., Ni₂₊.
- 8. (a) Zinc is a cofactor for carboxypeptidases.
- 9. (d) Some of the physiological diseases caused due to boron deficiency are internal cork of apple, top rot of tobacco. These diseases can be cured by application of small doses of sodium tetraborate in the soil.
- 11. (c) The leaves become distorted and sickle shaped and get clustered to form rosettes. This effect is known as 'little leaf disease'.
- 12. (c) Its deficiency causes 'whiptail disease' in cauliflower and cabbage. The leaves first show an interveinal mottling and the leaf margins may become gray and flaccid and finally brown.
- **13.** (a) Boron is absorbed by the plants as borate it is involved in the transport of carbohydrates (Sugar).
- (a) Cu-Copper takes part in electron transport as plastocyanin (between PS II and PSI) and cytochrome to oxygen.
 - Mg-Manganese is activator of a number of enzymes like reductases, oxidases, etc. taking part in respiration and photosynthesis.
 - Fe- Iron is component of e^- transferring biomolecules like cytochromes and ferredoxin. They are essential components of photosynthesis.

- 16. (c) Many elements become toxic in higher concentration than the normal e.g., Cu. Others are toxic even in smaller concentration e.g., Hg.
- 17. (b) Iron deficient plants develop pronounced interveinal chlorosis similar to that caused by Mg deficiency. Whereas in iron chlorosis the young leaves may become yellow or white with prominent green veins.
- (d) "Grey speck disease" in oat appears due to the deficiency of manganese, which leads to total failure of crop.
- (d) Calcium is required by plants in larger amounts hence it is called macro or tracer element.
- 22. (b) Recent research has shown that some elements, such as cobalt, vanadium and nickel, may be essential for certain plants in very small amounts.
- 23. (b) Zinc is absorbed by the plants in ionic form.
- 24. (a) Micro-elements are mostly involved in the functioning of enzymes, as cofactors or metal activators.
- 25. (a) Molybdenum is required for nitrogen fixation. Nitrate metabolism depends upon enzyme nitrate reductase. It is an activator of nitrate reductase. Therefore, the element is important for nitrogen fixation.
- 26. (d) Cu (6 μm/gm), Zn (20 μm/gm) and Mo (.1 μm/gm) are required for plant growth.
- 28. (b) Molybdenum is component of nitrogenase and it also acts as enzyme activator for nitrate reductase.
- 29. (d) Ferredoxin is Fe having electron carrier which participates in photosynthesis. It plays an important role in ETS, photosynthesis and respiration because iron is the part of cytochromes.

Mineral absorption

- 1. (a) Because inorganic materials move with water.
- (c) The use of energy of ATP in transferring solutes across membrane may be through an ATPase which creates a pH gradient across the membrane.
- (b) It is mode of mineral absorption which involves expenditure of metabolic energy. Energy is generally obtained from ATP.
- (a) The semipermeable membrane is responsible for absorption of mineral salts.
- 6. (a) Mineral salts are absorbed mostly in form of ions, i.e., anions and cations. Ions are accumulated by the plants against their concentration in the soil.
- (a) The carrier proteins usually transport solutes against their electrochemical gradient. Energy for transport is provided by ATP, electron transport chain and light.
- (a) This type of absorption is carried out by purely physical forces.

- 11. (c) The ash that is left after burning any dry part of the plant in a crucible, contains only mineral elements and is called plant ash.
- 12. (a) Maximum mineral salt absorption occurs by zone of elongation. No mineral salt absorption occurs by root hair zone. Mineral salt absorption occurs directly by cells of epiblema and not by root hair.
- 15. (d) In this process an ATP is used up. ATP molecule combine with carrier molecules and allow passage of substances against concentration gradient.
- (c) At 0° C, 5 gm ions are absorbed and at 20°C, 20gm ions are absorbed.

Energy is increased from $0^{\circ}C$ to 20° C, then the increase in ion absorption amount = 20 - 5 = 15 gm.

Nitrogen nutrition

- (d) Chief source of nitrogen for plants are the nitrates of calcium and potassium.
- (d) Nitrogen excess in soil cause susceptibility towards pathogen like fungi, bacteria.
- 4. (d) The deficiency of nitrogen causes chlorosis in leaves of the plants and the cell division as well as cell elongation is stopped, due to which plants remain dwarf and production of flowers, fruits and seeds is decreased.
- 6. (d) Nitrogen is absolutely essential for the synthesis of protein. In addition nitrogen is found in such important molecules as aminoacids, purines, pyrimidines etc. Purines, pyrimidines, RNA and DNA which are essential for protein synthesis.
- (a) Nitrogenase require high input of energy and anaerobic condition.
- 12. (a) The bacterium Rhizobium leguminosarum lives symbiotically in the root of pea. This bacteria are responsible for the nitrogen fixation.
- 14. (b) Nitrogen fixing bacteria as Rhizobium have symbiotic relationship with the roots of gram (leguminous) plants. This association produce nodules on roots.
- 15. (c) The bacteria (Rhizobium sps.) associated with the root nodules of legumes fix atmospheric nitrogen. It helps in increase of soil fertility because they are rich in nitrogen and adds nitrates in the soil.
- 16. (d) The bacterium Rhizobium infects the roots through the root hairs of groundnut plant and reproduce in the cells of cortex of roots. Simultaneously the division of cortex cells take place due to which the nodules are formed in the root.
- 19. (c) The important elements need to be replenished in crop fields are nitrogen, phosphorus and potassium. These are grouped as nitrogenous fertilizers, phosphate fertilizers and potash fertilizers. These are abbreviated as NPK.

- 21. (a) Nif gene is present in Rhizobium. It is responsible for the synthesis of enzyme nitrogenase which can fix atmospheric nitrogen. Rhizobium leguminosarum bacteria is found symbiotically associated in the root nodules of leguminous plant.
- 22. (c) Some bacteria such as Thiobacillus denitrificans, Pseudomonas aeruginosa and Micrococcus denitrificans also occur in the soil which convert the nitrate and ammonia into atmospheric free elemental nitrogen.
- (d) Frankia is symbiont in root nodules of several nonlegume plants like Casuarina and Alnus (Alder).
- **24.** (d) Nitrogenase is sensitive against O_2 .

Special modes of nutrition

- (a) Autotrophs are green plants capable of synthesizing their own food from raw material (CO₂, water and sunlight). Thus they are independent and self nourishing.
- (b) The heterotrophs, require both organic and inorganic substances from outside. All nongreen plants and animals, including human beings are heterotrophs.
- (d) Epiphytes are plants which live on other plants for space (shelter/support) only. They are therefore, called space parasites.
- (d) Partial parasite plants have chlorophyll and therefore, synthesize their organic food themselves. But they fulfil their mineral and water requirements from their host plants e.g., Viscum.
- (a) Cuscuta is found on outer side of the host and are total stem parasite.
- (b) Viscum album is a partial stem parasite that grows on silverfish, poplar, apple, walnut, oak etc. The parasite sends a primary haustorium into the host for sucking food.
- 9. (a) Insectivorous plants usually grow in water logged and swampy soil deficient in nitrogen compounds. These plants leaves trap and digest the insects and other small animals to get their nitrogen requirements.
- (b) Loranthus is another partial stem parasite. Loranthus is similar to viscum growing on Acacia, Mango, Dalbergia, Albizzia etc.
- 11. (c) Drosera is a herbaceous plant. These long special hair are generally referred to as tentacles. The glandular heads of the tentacles secrete sticky juice. Insect is attracted by the sticky fluid and tries to sit on the leaf, it becomes entangled in the sticky fluid.
- 12. (a) Orobanche is usually parasitic upon brinjal, tobacco. Balanophora occurs as a total root parasite in the roots of forest trees. Rafflesia is a total root parasite plant on Fig, Cissus and several other forest trees. They are largest with a diameter of 1m and weight of 11kg.

- 13. (a) The common example of partial root parasite is Santalum album. Which is an evergreen partial root parasite. It grows on the roots of Dalbergia sisso, Eucalyptus.
- 14. (c) The leaves are modified into pitchers. The pitchers of Sarracenia lack digestive enzymes and here the insects are decomposed by bacteria.
- 16. (b) Epiphytic roots develop in some orchids which grow as epiphytes upon the trunk or branches of trees. They absorb moisture with the help of special sponge like tissue called velamen.
- (b) Dionaea (Venus Flay Trap) is an American herb that possesses a rosette of long-petioled leaves.
- 19. (a) It is a total root parasite. The plant body consists of fine threads resembling hyphae of fungal mycelia. It lies completely inside the root of the host. It grows directly on the roots of Cissus and Figs.
- 21. (c) These insects die in the bladder and are decomposed in due course of time. After decomposition the nitrogenous substances are absorbed through the hair of bladder.
- 22. (b) A heterotrophic plant which obtains its food from other living organism without killing it, is called a parasite. The parasite sucks its food from the host with the help of specialized absorbing organs called haustoria.
- 23. (d) Because they grow in marshy or muddy soils, which are generally deficient in nitrogen. Plants usually grow in nitrogen deficient soils and fulfil their nitrogen requirement by digesting insects.
- 24. (a) Nepenthes khasiana is a green plant (photosynthetic plant) but shows heterotrophic nature for nitrogen supply, therefore, is called as carnivorous.
- 25. (d) Halophytes are those plants which grow in saline habitats, i.e., in salty marshes, alkaline soil etc. In halophytes the water is present in sufficient amount but due to high osmotic concentrations it is physiologically not available to normal plants. Such conditions are said to be physiologically dry e.g. Spartina, Atriplex, Portulaca.
- 27. (b) Dischidia: The pitcher is without lid and is used only for storing rain water with some mud.
- 30. (b) Carnivorous plants (Pitcher plant) are green plants. They manufacture their food themselves. Hence are autotrophic in nature. They behave like heterotrophic organisms for supplementing their nitrogen supply only through catching and digesting small animals like insects. Insect captured by carnivorous plants (*Drosera* and Sarracenia) partially meet their requirement of nitrogen.
- 31. (c) Monotropa, though usually referred to as a saprophyte, actually gets its nourishment from fungal mycelium, which surround its roots. Such association between roots of higher plants and fungi is known as mycorrhiza.

Critical Thinking Questions

- (a) Sulphur deficiency causes chlorosis in young leaves. Leaf tips and margins roll downwards and inwards. e.g., Tomato, Tea etc.
- (c) EDTA is buffer solution and it maintains the pH of culture medium.
- (c) Haber-bosch method is the best chemical method for fixing of nitrogen.
- (b) Fly-ash is a light airborne particulate matter. Coal also produces mineral ash. Some of which is discharged as fly ash.
- 9. (c) Chlorosis is the main symptom of nitrogen deficiency. As a result, the leaves gradually become pale or yellow. These symptoms first appear in old leaves and later in young leaves.
- (b) Aldrovanda (Water flea trap) is an aquatic free floating rootless insectivorous plant which possesses leaves similar to those of Dionaea.
- 11. (c) The absorption of ions, involving use of metabolic energy is called active absorption. Energy is generally obtained from ATP. Therefore, active absorption is linked to hydrolysis of ATP.
- 14. (a) Arceuthobium is the smallest angiospermic parasite. It is total parasite that grows on a number of forest trees including Pinus and Juniper.
- (c) Aulosira fertilissima (Blue-green algae) is an important nitrogen fixer of rice fields.

Assertion and Reason

- (a) Plants absorb essential nutrients from soil hence they lack excretory organs. Particulate matter is not taken as these lack mouth.
- (a) Leguminous plants have nodulated roots in which Rhizobium is present. So, these are able to fix nitrogen.
- (e) Insectivorous plants are autotrophic and heterotrophic as they capture insects to overcome their N₂ deficiency.
- 4. (b) Among the sixteen essential plant nutrients nitrogen, phosphorus and potash are the most common nutrients found deficient in Indian soil. Supply of these nutrients to soil artificially through fertilizers is necessary to keep the soil rich in plant nutrients for achieving maximum yield. Irrigation practices also helpful in enhancing the crop yield. In this way both fertilizers and irrigation are equally important for high crop yield.
- 5. (c) Solution culture is being used for raising flowers and vegetables at home. This soilless production of plants is called hydroponics. A solution having all the essential elements in proper proportion is called normal or balanced nutrient solution.

- 6. (a) Cauliflower plants very commonly show whiptail disease. The leaves first shown an interveinal mottling and the leaf margins may become gray and flaccid and finally brown.
- 7. (a) The upper surface of each lamina lobe of *Dionaea* contains 3 sensitive spines. The leaf margin bears 12-20 curved spiny teeth. The marginal teeth get interlocked. So the prey cannot escape. It is digested by the secretion of reddish glands.
- 8. (e) Plants absorb nitrogen in the form of NO₃⁻ (nitrate) or NH₄⁺ (ammonium ion). They can absorb NO₂⁻ (nitrite) as well but the same does not accumulate in the soil. Only a small quantity of nitrate or ammonium is available in the lithosphere. Therefore, nitrogen is the most critical element. Other critical elements are phosphorus and potassium.
- 9. (b) Magnesium is a constituent of the chlorophyll molecule, without which photosynthesis would not occur. Many of the enzymes involved in carbohydrate metabolism require magnesium as an activator. Magnesium is also an activator for those enzymes involved in the synthesis of nucleic acids (DNA, RNA) from nucleotide polyphosphate.
- 10. (a) Manganese plays an important role in nitrate reduction. Manganese acts as an activator for the enzymes nitrite reductase and hydroxylamine reductase. The preference of ammonia over nitrate as a nitrogen source by the manganese – deficient cells supports the above mentioned analysis of the role of manganese.
- 11. (c) Rhizobium species (e.g., Leguminosarum, R.lupini etc) live in symbiotic association in the root nodules of leguminous plants like, pea, gram etc. In the soil the bacteria cannot fix nitrogen. After entering the legume root, the bacterium induces cell membrane. A pink-red pigment called leghaemoglobin lines the membrane and protects the bacteriods from the oxygen.
- 12. (c) Due to deficiency of sulphur plant shows chlorosis (i.e., yellowing due to degradation of chlorophyll) followed by anthocyanin development. The younger leaves show chlorosis before older ones. Sulphur is not the constituent of chlorophyll. The main constituent of chlorophyll is magnesium.
- 13. (e) The most important diseases due to copper deficiency are exanthema and reclamation. Exanthema is a disease of fruit tree. Reclamation is disease of cereals that occurs chiefly on newly reclaimed peat land.
- 14. (a) Micro elements are those essential elements which are required by plants in traces only, less than 1 mg/gm of dry matter. Iron occurs in the concentration of less than 1 mg/gm.
- 15. (b) In solution culture, iron is added as Fe-EDTA. The agent which keeps metals in the soluble state is called chelating agent or ligand. Fe-EDTA complex is called chelate. The soilless production of plants is called solution culture or hydroponics. The cost of setting up a hydroponic system is very high.

ET Self Evaluation Test

- 1. The element which is required by the sea plants is
 - (a) Cobalt
- (b) Zinc
- (c) Copper
- (d) Sodium
- 2. The ability of the venus fly trap of capture insects is due to

[CBSE PMT 2005]

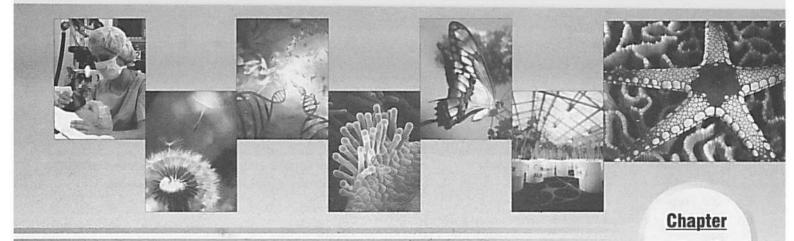

- (a) Chemical stimulation by the prev
- (b) A passive process requiring no special ability on the part of the plant
- (c) Specialized "muscle-like" cells
- (d) Rapid turgor pressure changes
- It is possible to determine whether an element is essential by observing growth of plants [AIEEE Pharmacy 2004]
 - (a) On soil form which the particular element is removed
 - (b) On soil in which only the particular element is present
 - (c) On an inert medium to which solution of only the particular element is added
 - (d) On an inert medium to which a nutrient solution excluding that particular element, is added
- 4. Which statement is wrong
 - (a) Plants take very little amount of mineral elements from soil
 - (b) Plants absorb one thing at a time either water or mineral salt
 - (c) Root hair absorb water and minerals together
 - (d) Mineral absorption primarily takes place by active method
- Chlorosis, etiolation and albinism are caused by the deficiency of [JIPMER 1994]
 - (a) Iron, light and certain genes
 - (b) Zinc, iron and magnesium
 - (c) Magnesium, iron, zinc, light and certain genes
 - (d) Magnesium, zinc and light
- The association between ants and members of family rubiaceae is [AMU (Med.) 1997; MP PMT 2013]
 - (a) Ornithophily
- (b) Entomophily
- (c) Myrmecophily
- (d) Anemophily

- A trace element essential for plant growth and radioactive isotope which is used in cancer therapy is known as
 - (a) Cobalt
- (b) Iron
- (c) Calcium
- (d) Sodium
- The enzyme commonly presents in insectivorous plants to fulfil the need of their specific habit
 - (a) Trypsin
- (b) Pepsin
- (c) Pectinase
- (d) Cellulase
- An example of a parasitic plant that is also strictly epiphytic is
 - (a) Cuscuta (dodder)
- (b) Viscum (mistletoe)
- (c) Rafflesia
- (d) Orobanche

S Answers and Solutions

1	d	2	d	3	d	4	b	5	C
6	C	7	a	8	ь	9	b	1	

- 2. (d) In Dionaea (Venus Fly Trap) an insect that happens to alight over the lamina and touch a sensitive spine twice in quick succession, causes the folding of the lamina. The curved marginal spines get interlocked and the insect gets trapped.
- (c) The ants obtain food and shelter from the plant and they protect the plant from other animals.
- (b) The insect is killed and its proteins are digested by pepsin.
- (b) Viscum is a partial stem parasite with edible berries having sticky pulp.

In photosynthesis process, 'energy rich compounds like carbohydrates are synthesized from simple inorganic compounds like carbon dioxide and water in the presence of chlorophyll and sunlight with liberation of oxygen'. The process of photosynthesis can also be defined as "transformation of photonic energy (i.e., light or radiant energy) into chemical energy".

About 90% of total photosynthesis in world is done by algae in oceans and in freshwater. More than 170 billion tonnes of dry matter are produced annually by this process. Further CO_2 fixed annually through photosynthesis is about $7.0\times10^{13}kg$. Photosynthesis is a reductive, anabolic and endothermic reaction. Photosynthesis helps to maintain the equilibrium position of O_2 and CO_2 in the atmosphere.

Historical background

Before seventeenth century it was considered that plants take their food from the soil.

- ☐ Van Helmont (1648) concluded that all food of the plant is derived from water and not from soil.
- ☐ **Stephen Hales** (Father of Plant Physiology) (1727) reported that plants obtain a part of their nutrition from air and light may also play a role in this process.
- ☐ **Joseph Priestley** (1772) demonstrated that green plants (mint plant) purify the foul air (i.e., Phlogiston), produced by burning of candle, and convert it into pure air (i.e., Dephlogiston).
- **Jan Ingen-Housz** (1779) concluded by his experiment that purification of air was done by green parts of plant only and that too in the presence of sunlight. Green leaves and stalks liberate dephlogisticated air (Having O_2) during sunlight and phlogisticated air (Having CO_2) during dark.

- \square **Jean Senebier** (1782) proved that plants absorb CO_2 and release O_2 in the presence of light. He also showed that the rate of O_2 evolution depends upon the rate of CO_2 consumption.
- \square **Nicolus de Saussure** (1804) showed the importance of water in the process of photosynthesis. He further showed that the amount of CO_2 absorbed is equal to the amount of O_2 released.
- ☐ Julius Robert Mayer (1845) proposed that light has radiant energy and this radiant energy is converted to chemical energy by plants, which serves to maintain life of the plants and also animals.
- \square Liebig (1845) indicated that main source of carbon in plants is CO_2 .
- \square Bousingault (1860) reported that the volume of CO_2 absorbed is equal to volume of O_2 evolved and that CO_2 absorption and O_2 evolution get start immediately after the plant was exposed to sunlight.
- ☐ Julius Von Sachs (1862) demonstrated that first visible product of photosynthesis is starch. He also showed that chlorophyll is confined to the chloroplasts.
- \square **Melvin Calvin** (1954) traced the path of carbon in photosynthesis (Associated with dark reactions) and gave the C_3 cycle (Now named Calvin cycle). He was awarded Nobel prize in 1961 for the technique to trace metabolic pathway by using radioactive isotope.
- ☐ Huber, Michel and Deisenhofer (1985) crystallised the photosynthetic reaction center from the purple photosynthetic bacterium, Rhodopseudomonas viridis. They analysed its structure by X-ray diffraction technique. In 1988 they were awarded Nobel prize in chemistry for this work.

Photosynthesis in higher plants

Chloroplast (The site of photosynthesis): Chloroplast are green plastids which function as the site of photosynthesis in eukaryotic photoautotrops. It fixes CO_2 into carbohydrate.

Photosynthetic unit can be defined as number of pigment molecules required to affect a photochemical act, that is the release of a molecule of oxygen. Park and Biggins (1964) gave the term quantasome for photosynthetic units which is equivalent to 230 chlorophyll molecules.

Chloroplast pigments: Pigments are the organic molecules that absorb light of specific wavelengths in the visible region due to presence of conjugated double bonds in their structures. The chloroplast pigments are fat soluble and are located in the lipid part of the thylakoid membranes (fret membrane). There is a wide range of chloroplastic pigments which constitute more than 5% of the total dry weight of the chloroplast. They are grouped under two main categories:

(1) **Chlorophylls**: Chlorophyll 'a' is found in all the oxygen evolving photosynthetic plants except photosynthetic bacteria. Reaction centre of photosynthesis is formed of chlorophyll a. It occurs in several spectrally distinct forms which perform distinct roles in photosynthesis (e.g., Chl a_{680} or P_{680} , Chl a_{700} or P_{700} , etc.). It directly takes part in photochemical reaction. Hence, it is termed as primary photosynthetic pigment. Other photosynthetic pigments including chlorophyll b, c, d and e; carotenoids and phycobilins are called accessory pigments because they do not directly take part in photochemical act. They absorb specific wavelengths of light and transfer energy finally to chlorophyll a through electron spin resonance.

Chlorophyll a is bluish-green while chlorophyll b is olive-green. Both are soluble in organic solvents like alcohol, acetone etc. Chlorophyll is a green pigment because it does not absorb green light (but reflect green light) Chlorophyll a ($C_{55}H_{72}O_5N_4Mg$) possesses — CH_3 (methyl group), which is replaced by — CHO (an aldehyde) group in chlorophyll b ($C_{55}H_{70}O_6N_4Mg$). Chlorophyll molecule is made up of a squarish tetrapyrrolic ring known as head and a phytol alcohol called tail. The magnesium atom is present in the central position of tetrapyrrolic ring. The four pyrrole rings of porphyrin head are linked together by methine (CH =) groups forming a ring system.

When central Mg is replaced by Fe, the chlorophyll becomes a green pigment called 'cytochrome' which is used in photosynthesis (Photophosphorylation) and respiration both.

(2) Carotenoids: They are sometimes called lipochromes due to their fat soluble nature. They are lipids and found in nongreen parts of plants. Light is not necessary for their biosynthesis. Carotenoids mainly absorb violet, indigo and blue wavelength of spectrum in higher plants and transfer it to Chl. a and thus act as accessory pigments. They protect the chlorophyll molecules from photo-oxidation by picking up nascent oxygen and converting it into harmless molecular stage. Carotenoids can be classified into two groups namely carotenes and xanthophyll.

 (i) Carotenes: They are orange red in colour and have general formula C₄₀H₅₆. They are isolated from carrot.

They are found in all groups of plants i.e., from algae to angiosperms. Some of the common carotenes are α , β , γ and δ carotene; phytotene, lycopene, neurosporene etc. The lycopene is a red pigment found in ripe tomato and red pepper fruits. The β -carotene on hydrolysis gives vitamin A, hence the carotenes are also called provitamin A. β -carotene is black yellow pigment of carrot roots.

(ii) **Xanthophylls**: They are yellow coloured carotenoid also called xanthols or carotenols. They contain oxygen also along with carbon and hydrogen and have general formula $C_{40}H_{56}O_2$.

Lutein $(C_{40}H_{56}O_2)$ a widely distributed xanthophyll which is responsible for yellow colour in autumn foliage. Fucoxanthin $(C_{40}H_{56}O_6)$ is another important xanthophyll present in Phaeophyceae (Brown algae).

(3) Phycobilins: These pigments are mainly found in bluegreen algae (Cyanobacteria) and red algae. These pigments have open tetrapyrrolic in structure and do not bear magnesium and phytol chain.

Blue-green algae have more quantity of phycocyanin and red algae have more phycoerythrin. Phycocyanin and phycoerythrin together form phycobilins. These water soluble pigments are thought to be associated with small granules attached with lamellae. Like carotenoids, phycobilins are accessory pigments i.e., they absorb light and transfer it to chlorophyll a.

Nature of light: Sunlight is a type of energy called radiant energy or electromagnetic energy. This energy, according to electromagnetic wave theory (Proposed by James Clark Maxwell, 1960), travels in space as waves. The distance between the crest of two adjacent waves is called a wavelength (λ). Shorter the wavelength greater the energy.

The unit quantity of light energy in the quantum theory is called quantum (hv), whereas the same of the electromagnetic field is called photon. Solar radiation can be divided on the basis of wavelengths. Radiation of shortest wavelength belongs to cosmic rays whereas that of longest wavelength belong to radio waves. Visible light lies between wavelengths of ultra-violet and infra-red. The visible spectrum of solar radiations are primarily absorbed by carotenoids of the higher plants are violet and blue. However, out of blue and red wavelengths, blue light carry more energy.

Shortest wavelength — Longest wavelength

Maximum energy Minimum energy

Visible light: 390nm (3900Å) to 760nm (7600Å). Violet (390–430nm), blue (430–470nm), blue-green (470–500nm), green (500–580nm), yellow (580–600nm), orange (600–650nm), orange-red (650–660nm) and red (660–760nm) Far-red (700–760nm). Infra-red 760nm – 100μ m. Ultraviolet 100–390nm. Solar radiations 300nm (ultraviolet) to 2600nm (infra-red).

Photosynthetically active radiation (PAR) is 400–700nm. Leaves appear green because chlorophylls do not absorb green light. The same is reflected and transmitted through leaves.

Absorption and action spectra: The curve representing the light absorbed at each wavelength by pigment is called absorption spectrum. Curve showing rate of photosynthesis at different wavelengths of light is called action spectrum.

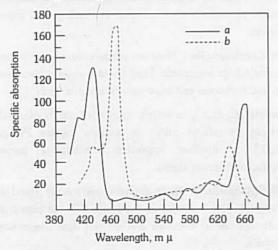

Fig: 4.3-1 Absorption spectra of chlorophylls a and b

Absorption spectrum is studied with the help of spectrophotometer. The absorption spectrum of chlorophyll a and chlorophyll b indicate that these pigments mainly absorb blue and red lights. (430 nm and 662 nm for chlorophyll a, 455 nm and 644 nm for chlorophyll b). Action spectrum shows that maximum photosynthesis takes place in blue and red regions of spectrum. The first action spectrum of photosynthesis was studied by T.W. Engelmann (1882) using green alga Spirogyra and oxygen seeking bacteria.

In this case actual rate of photosynthesis in terms of oxygen evolution or carbon dioxide utilisation is measured as a function of wavelength.

Mechanism of photosynthesis

On the basis of discovery of Nicolas de Saussure that "The amount of O_2 released from plants is equal to the amount of CO_2 absorbed by plants", it was considered that O_2 released in photosynthesis comes from CO_2 , but Ruben proved that this concept is wrong.

In 1930, C.B. Van Niel proved that, sulphur bacteria use H_2S (in place of water) and CO_2 to synthesize carbohydrates as follows:

$$6CO_2 + 12H_2S \longrightarrow C_6H_{12}O_6 + 6H_2O + 12S$$

This led Van Niel to the postulation that in green plants, water (H_2O) is utilized in place of H_2S and O_2 is evolved in place of sulphur (S). He indicated that water is an electron donor in photosynthesis.

$$6CO_2 + 12H_2O \longrightarrow C_6H_{12}O_6 + 6H_2O + 6O_2$$

This was confirmed by Ruben and Kamen in 1941 using Chlorella a green alga.

They used isotopes of oxygen in water, i.e., H_2^{18} O instead of H_2 O (normal) and noticed that liberated oxygen contains 18 O of water and not of CO_2 . The overall reaction can be given as under:

$$6CO_2 + 12H_2^{-18}O \xrightarrow{\text{Light}} C_6H_{12}O_6 + 6^{18}O_2 + 6H_2O_6$$

During photosynthesis the O_2 in glucose comes from carbondiowater.

Modern concept of photosynthesis

Photosynthesis is an oxidation reduction process in which water is oxidised to release O_2 and CO_2 is reduced to form starch and sugars.

Scientists have shown that photosynthesis is completed in two phases.

- (1) Light phase or Photochemical reactions or Light dependent reactions or Hill's reactions: During this stage energy from sunlight is absorbed and converted to chemical energy which is stored in ATP and $NADPH + H^+$.
- (2) Dark phase or Chemical dark reactions or Light independent reactions or Blackman reaction or Biosynthetic phase: During this stage carbohydrates are synthesized from carbon dioxide using the energy stored in the ATP and NADPH formed in the light dependent reactions.

Evidence for light and dark reactions in photosynthesis:

- (1) Physical separation of chloroplast into grana and stroma fractions: It is now possible to separate grana and stroma fractions of chloroplast. If light is given to grana fraction in presence of suitable H-acceptor and in complete absence of CO₂, then ATP and NADPH₂ are produced (i.e., assimilatory powers). If these assimilatory powers (ATP and NADPH₂) are given to stroma fraction in presence of CO₂ and absence of light, then carbohydrates are formed.
- (2) Experiments with intermittent light or Discontinuous light: Rate of photosynthesis is faster in intermittent light (Alternate light and dark periods) than in continuous light. It is because light reaction is much faster than dark reaction, so in continuous light, there is accumulation of ATP and NADPH2 and hence reduction in rate of photosynthesis but in discontinuous light, ATP and NADPH2 formed in light are fully consumed during dark in reduction of CO2 to carbohydrates. Accumulation of NADPH2 and ATP is prevented because they are not produced during dark periods.
- (3) **Temperature coefficient studies**: Blackman found that Q_{10} was greater than 2 in experiment when photosynthesis was rapid and that Q_{10} dropped from 2 often reaching unity, i.e., 1 when the rate of photosynthesis was low. These results show that in photosynthesis there is a dark reaction (Q_{10} more than 2) and a photochemical or light reaction (with Q_{10} being unity).

$$Q_{10} = \frac{\text{Reaction rate of } (t+10)^{\circ}C}{\text{Reaction at } t^{\circ}C}$$

UNIVERSAL BOOK DEPOT 1960

Light reaction (Photochemical reactions): Light reaction occurs in grana fraction of chloroplast and in this reaction are included those activities, which are dependent on light. Assimilatory powers (ATP and NADPH₂) are mainly produced in this light reaction.

Robin Hill (1939) first of all showed that if chloroplasts extracted from leaves of *Stellaria media* and *Lamium album* are suspended in a test tube containing suitable electron acceptors, e.g., Potassium ferroxalate (Some plants require only this chemical) and potassium ferricyanide, oxygen is released due to photochemical splitting of water. Under these conditions, no CO_2 was consumed and no carbohydrate was produced, but light-driven reduction of the electron acceptors was accompained, by O_2 evolution.

$$4Fe^{3+} + 2H_2O \longleftrightarrow 4Fe^{2+} + 4H^+ + O_2 \uparrow$$
Electron acceptor Electron donor Reduced Product

The splitting of water during photosynthesis is called photolysis. This reaction on the name of its discoverer is known as Hill reaction.

Hill reaction proves that

- (1) In photosynthesis oxygen is released from water.
- (2) Electrons for the reduction of CO₂ are obtained from water [i.e., a reduced substance (hydrogen donor) is produced which later reduces CO₂].

Dichlorophenol indophenol is the dye used by Hill for his famous Hill reaction.

According to Arnon (1961), in this process light energy is converted to chemical energy. This energy is stored in ATP (this process of ATP formation in chloroplasts is known as photophosphorylation) and from electron acceptor NADP+, a substance found in all living beings NADP*H is formed as hydrogen donor. Formation of hydrogen donor NADPH from electron acceptor NADP+ is known as photoreduction or production of reducing power NADPH.

Light phase can be explained under the following headings:

(1) Transfer of energy: When photon of light energy falls on chlorophyll molecule, one of the electrons pair from ground or singlet state passes into higher energy level called excited singlet state. It comes back to hole of chlorophyll molecule within 10⁻⁹ seconds.

This light energy absorbed by chlorophyll molecule before coming back to ground state appears as radiation energy, while that coming back from excited singlet state is called fluorescence and is temperature independent. Sometimes the electron at excited singlet state gets its spin reversed because two electrons at the same energy level cannot stay; for sometime it fails to return to its partner electron. As a result it gets trapped at a high energy level.

Due to little loss of energy, it stays at comparatively lower energy level (Triplet state) from excited singlet state. Now at this moment, it can change its spin and from this triplet state, it comes back to ground state again losing excess of energy in the form of radiation. This type of loss of energy is called as phosphorescence.

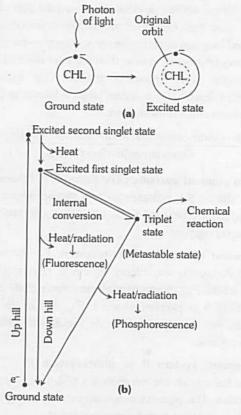

Fig: 4.3-2 (a) Photoexcitation of chlorophyll molecule *i.e.*, of its atoms (b) Movement of electron due to photoexcitation of pigment molecule

When electron is raised to higher energy level, it is called at second singlet state. It can lose its energy in the form of heat also. Migration of electron from excited singlet state to ground state along with the release of excess energy into radiation energy is of no importance to this process. Somehow when this excess energy is converted to chemical energy, it plays a definite constructive role in the process.

(2) Quantum yield

- (i) Rate or yield of photosynthesis is measured in terms of quantum yield or O_2 evolution, which may be defined as, "Number of O_2 molecules evolved per quantum of light absorbed in photosynthesis."
- (ii) Quantum requirement in photosynthesis = 8, i.e., 8 quanta of light are required to evolve one mol. of O_2 .
- (iii) Hence quantum yield = 1/8 = 0.125 (i.e., a fraction of 1) as 12%.
- (3) Emerson effect and Red drop: R. Emerson and C.M. Lewis (1943) observed that the quantum yield of photosynthesis decreases towards the far red end of the

spectrum (680nm or longer). Quantum yield is the number of oxygen molecules evolved per light quantum absorbed. Since this decrease in quantum yield is observed at the far region or beyond red region of spectrum is called red drop.

Emerson et al. (1957) further observed that photosynthetic efficiency of light of 680nm or longer is increased if light of shorter wavelengths (Less than 680nm) is supplied simultaneously. When both short and long wavelengths were given together the quantum-yield of photosynthesis was greater than the total effect when both the wavelengths were given separately. This increase in photosynthetic efficiency (or quantum yield) is known as Emerson effect or Emerson enhancement effect.

 $E = \frac{\text{Quantum yieldin combined beam-Quantum yieldin red beam}}{\text{Quantum yieldin far red beam}}$

- (4) Two pigment systems: The discovery of Emerson effect has clearly shown the existence of two distinct photochemical processes, which are believed to be associated with two different specific group of pigments.
- (i) **Pigment system I or Photosystem I**: The important pigments of this system are chlorophyll a 670, chlorophyll a 683, chlorophyll a 695, P_{700} . Some physiologists also include carotenes and chlorophyll b in pigment system I. P_{700} acts as the reaction centre. Thus, this system absorbs both wavelengths shorter and longer than 680nm.
- (ii) **Pigment system II or photosystem II**: The main pigments of this system are chlorophyll a 673, P_{680} , chlorophyll b and phycobilins. This pigment system absorbs wavelengths shorter than 680nm only. P_{680} acts as the reaction centre.

Pigment system I and II are involved in non-cyclic electron transport, while pigment system I is involved only in cyclic electron transport. Photosystem I generates strong reductant NADPH. Photosystem II produces a strong oxidant that forms oxygen from water.

Table: 4.3-1 Comparison of photosystem I and photosystem II

S. No.	Photosystem I	Photosystem II
(1)	PS I lies on the outer surface of the thylakoids.	PS II lies on the inner surface of the thylakoid.
(2)	In this system molecular oxygen is not evolved.	As the result of photolysis of water molecular oxygen is evolved.
(3)	Its reaction center is P700.	Its reaction center is P680.
(4)	It participates both in cyclic and noncyclic photophosphorylation.	It participates only in noncyclic photophosphorylation.
(5)	It receives electrons from photosystem II.	It receives electrons from photolytic dissociation of water.
(6)	It is not related with photolysis of water.	It is related with photolysis of water.

(5) **Photophosphorylation**: Light phase includes the interaction of two pigment systems. PS I and PS II constitute various type of pigments. Arnon showed that during light reaction not only reduced NADP is formed and oxygen is evolved but ATP is also formed. This formation of high energy phosphates (ATP) is dependent on light hence called photophosphorylation.

Photophosphorylation is of two types:

(i) Cyclic photophosphorylation: The system is found dominantly in bacteria. It involves only PS I. Flow of electron is cyclic. If NADP is not available then this process will occur. When the photons activate PS I, a pair of electrons are raised to a higher energy level. They are captured by primary acceptor which passes them on to ferredoxin, plastoquinone, cytochrome complex, plastocyanin and finally back to reaction centre of PS I i.e., P_{700} . At each step of electron transfer, the electrons lose potential energy. Their trip down hill is caused by the transport chain to pump H^+ across the thylakoid membrane. The proton gradient, thus established is responsible for forming (2 molecules) ATP. No reduction of NADP to NADPH+ H^+ . ATP is synthesized at two steps.

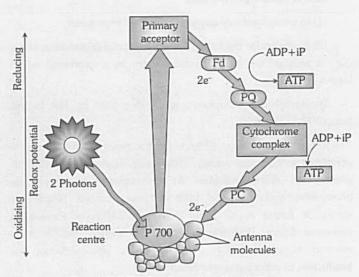

Fig: 4.3-3 Cyclic photophosphorylation

(ii) Non cyclic photophosphorylation: The system is dominant in green plants. It involves both PS-I and PS-II. Flow of electrons is unidirectional. Here electrons are not cycled back and are used in the reduction of NADP to NADPH2. Here H2O is utilized and O2 evolution occurs. In this chain high energy electrons released from 'P-680' do not return to 'P-680' but pass through pheophytin, plastoquinone, cytochrome b_6 f complex, plastocyanin (Cu containing pigment) and then enter P-700. In this transfer of electrons from plastoquinone (PQ) to cytochrome b₆-f complex, ATP is synthesized. Because in this process high energy electrons released from 'P-680' do not return to 'P-680' and ATP (1 molecules) this is called Noncyclic formed, photophosphorylation. ATP is synthesized at only one step.

UNIVERSAL BOOK DEPOT 1960

This non-cyclic photophosphorylation is also known as Zscheme (because of shape of path of electron-flow) and this was given by Hill and Bendall (1960). Non-cyclic photophosphorylation or Z-scheme is inhibited by CMU and DCMU.

(DCMU is a herbicide which kills the weed by inhibiting CO_2 fixation as it is a strong inhibitor of PS-II).

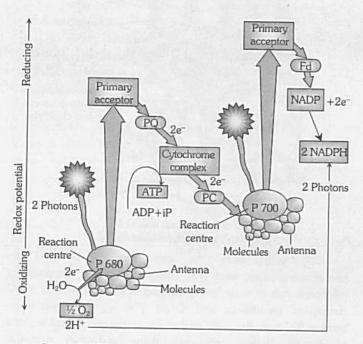

Fig: 4.3-4 Non cyclic photophosphorylation (Z-scheme)

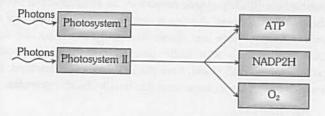

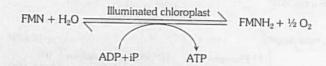

Fig: 4.3-5 Final products of light reactions

Pseudocyclic photophosphorylation: Arnon and his demonstrated yet another kind of coworker (1954) photophosphorylation. They observed that even in absence of CO2 and NADP, if chlorophyll molecules are illuminated, it can produce ATP from ADP and iP (Inorganic phosphate) in presence of FMN or vit. K and oxygen. The process is thus very simple and requires no net chemical change for the formation of ATP and water. Arnon called this oxygen dependent FMN catalysed photophosphorylation or pseudocyclic photophosphorylation which involves the reduction of FMN with the production of oxygen. FMN is an auto-oxidisable hydrogen acceptor with the effect that the reduced FMN is reoxidised by oxygen. Thus the process can continue repeatedly to produce ATP.

Since this process can be continuously self repeated, it appears that a single molecule of water should be sufficient to operate pseudocyclic photophosphorylation to meet the requirement of ATP.

Dark phase: The pathway by which all photosynthetic eukaryotic organisms ultimately incorporate CO_2 into carbohydrate is known as carbon fixation or photosynthetic carbon reduction (PCR) cycle or dark reactions.

The dark reactions are sensitive to temperature changes, but are independent of light hence it is called dark reaction, however it depends upon the products of light reaction of photosynthesis, i.e., NADP .2H and ATP.

The carbon dioxide fixation takes place in the stroma of chloroplasts because it has enzymes essential for fixation of ${\it CO}_2$ and synthesis of sugar.

The techniques used for studying different steps were Radioactive tracer technique using ¹⁴C (Half life – 5720 years), Chromatography and Autoradiography and the material used was Chlorella (Cloacal alga) and Scenedesmus (these are microscopic, unicellular algae and can be easily maintained in laboratory).

The assimilation and reduction of ${\it CO}_2$ takes place in this reaction by which carbohydrate is synthesized through following three pathways:

(1) **Calvin cycle**: Calvin and Benson discovered the path of carbon in this process. This is known as C_3 cycle because CO_2 reduction is cyclic process and first stable product in this cycle is a 3-C compound (i.e., 3-Phosphoglyceric acid or 3-PGA).

Calvin cycle is divided into three distinct phases : Carboxylation, Glycolytic reversal, regeneration of RuBP.

In this cycle, CO_2 acceptor molecule is RuBP or RuDP (i.e., Ribulose 1, 5-biphosphate or Ribulose 1, 5-diphosphate). There occurs covalent bonding of CO_2 to RuBP and the enzyme catalyzing this reaction is RuBP-carboxylase/oxygenase (Rubisco).

As calvin cycle takes in only one carbon (as CO_2) at a time, so it takes six turns of the cycle to produce a net gain of six carbons (i.e., hexose or glucose).

In this cycle, for formation of one mole of hexose sugar (Glucose), 18 ATP and 12 NADPH₂ are used.

The plants in which this pathway of ${\it CO}_2$ reduction occurs, are called C-3 plants.

UNIVERSAL BOOK DEPOT 1960

662 Photosynthesis in Higher Plants

About 85% of plant species are C-3 plants, including cereals (e.g., barley, rice, oat, wheat), groundnut, sugarbeet, cotton, tobacco, spinach, soybean most trees and lawn grasses etc.

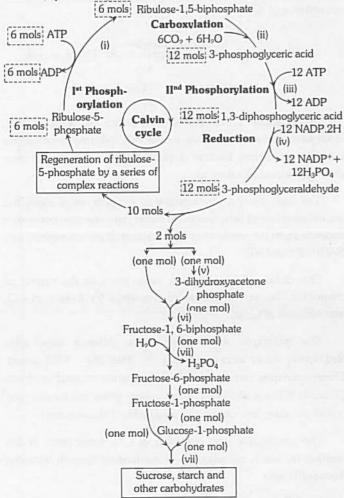

Fig: 4.3-6 Simplified diagram of Calvin cycle

Enzyme: (i) Phosphopentokinase, (ii) Carboxydismutase, (iii) Phosphoglyceric kinase, (iv) Triose phosphate dehydrogenase, (v) Phosphotriose isomerase, (vi) Aldolase, (vii) Phosphatase

(2) Hatch and Slack cycle (C_4 cycle): Kortschak and Hart supplied CO_2 to the leaves of sugarcane, they found that the first stable product is a four carbon (C_4) compound oxalo acetic acid instead of 3-carbon atom compound. The detailed study of this cycle has introduced by M.D. Hatch and C.R. Slack (1966). So it is called as "Hatch and Slack cycle". The stable product in C_4 plant is a dicarboxylic substance. Hence it is called dicarboxylic acid cycle or DCA-cycle. C_4 plants are true xerophytic plants. They are adapted for hot and dry climate.

The important C_4 plants are sugarcane, maize, Sorghum, Cyperus rotundus, Digitaria brownii, Amaranthus, etc. These plants have "Kranz" (German term meaning halo or wreath) type of leaf anatomy. The vascular bundles, in C_4 leaves are surrounded by a layer of bundle sheath cells that contain large number of chloroplasts. The chloroplasts in C_4 leaves are dimorphic (Two morphologically distinct types). The chloroplasts of bundle sheath cells are larger in size and arranged centripetally. They contain starch grains but lack grana. The mesophyll cells, on the other

hand, contain normal types of chloroplasts. Mesophyll and bundle sheath cells are connected by plasmodesmata. The mesophyll cells perform C_4 cycle and the cells of bundle sheath perform C_3 cycle.

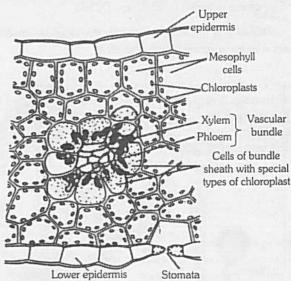

Fig: 4.3-7 Cross section of leaf showing "kranz" type of anatomy

 CO_2 taken from the atmosphere is accepted by phosphoenolpyruvic acid (PEP) present in the chloroplasts of mesophyll cells of these leaves, leading to the formation of a 4-C compound, oxaloacetic acid (OAA). This acid is converted to another 4-C acid, the malic acid which enters into the chloroplasts of bundle sheath cells and there undergoes oxidative decarboxylation yielding pyruvic acid (a 3-C compound) and CO_2 . CO_2 released in bundle sheath cells reacts with Ribulose-1,5-biphosphate (RuBP) already present in the chloroplasts of bundle sheath cells and thus Calvin cycle starts from here. Pyruvic acid reenters mesophyll cells and regenerates phosphoenol pyruvic acid. CO_2 after reacting with RuBP gives rise to sugars and other carbohydrates. In C_4 plants, there are 2 carboxylation reactions, first in mesophyll chloroplast and second in bundle sheath chloroplast.

UNIVERSAL BOOK DEPOT 1960

 C_4 plants are better photosynthesizers. There is no photorespiration in these plants. In C_4 plants, for formation of one molecule of hexose (glucose) 30 ATP and 12 NADPH $_2$ are required.

Characteristics of C4 cycle

- (1) C_4 species have greater rate of CO_2 assimilation than C_3 species. This is on account of the fact that
 - (i) PEP carboxylase has great affinity for CO2.
- (ii) C_4 plants show little photorespiration as compared to C_3 plants, resulting in higher production of dry matter.
- (2) C₄ plants are more adapted to environmental stresses than C₃ plants.
- (3) CO_2 fixation by C_4 plants requires more ATP than that by C_3 plants. This additional ATP is needed for conversion of pyruvic acid to phosphoenol pyruvic acid and its transport.
- (4) CO_2 acceptor molecule in C_4 plants is PEP. Further, PEP-carboxylase (PEPCO) is the key enzyme (RuBP-carboxylase enzyme is negligible or absent in mesophyll chloroplast, but is present in bundle sheath chloroplast).
- (3) Crassulacean acid metabolism (CAM): This dark CO_2 fixation pathway proposed by Ting (1971). It operates in succulent or fleshy plants e.g., Cactus, Sedum, Kalanchoe, Opuntia, Agave, Orchid, Pineapple and Bryophyllum helping them to continue photosynthesis under extremely dry condition.

The stomata of succulent plants remain closed during day and open during night to avoid water loss (Scotoactive stomata). They store CO_2 during night in the form of malic acid in presence of enzyme PEP carboxylase. The CO_2 stored during night is used in Calvin cycle during day time. Succulents refix CO_2 released during respiration and use it during photosynthesis.

This diurnal change in acidity was first discovered in crassulacean plants e.g., Bryophyllum. So it is called as crassulacean acid metabolism.

Formation of malic acid during dark is called acidification or phase-I. Release of CO_2 for actual photosynthesis during day is called deacidification or phase-II.

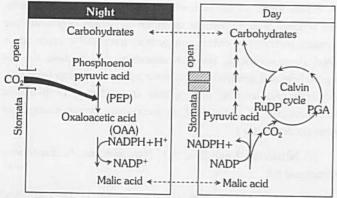

Fig: 4.3-9 Mechanism of CAM

Characteristics of CAM pathway

- (1) There is decrease in pH during the night and increase in pH during the day.
- (2) CAM plants have enzymes of both C_3 and C_4 cycle in mesophyll cells. This metabolism enable CAM plants to survive under xeric habitats. These plants have also the capability of fixing the CO_2 lost in respiration.

(3) Malic acid is stored in the vacuoles during the night which is decarboxylated to release CO₂ during the day.

CO₂ compensation point

In photosynthesis, CO_2 is utilized in presence of light to release O_2 whereas in respiration, O_2 is taken and CO_2 is released. If light factor is saturating, there will be certain CO_2 concentration at which rate of photosynthesis is just equal to rate of respiration or photosynthesis just compensates respiration or apparent photosynthesis is nil. It is called CO_2 compensation point.

 \square CO_2 compensation point is very low in C_4 plants, i.e, 0 to 5 ppm whereas high CO_2 compensation point is found in C_3 plants, i.e., 25 to 100 ppm.

Photorespiration or CO2 Cycle

Decker and Tio (1959) reported that light induces oxidation of photosynthetic intermediates with the help of oxygen in tobacco. It is called as photorespiration. The photorespiration is defined by Krotkov (1963) as an extra input of O_2 and extra release of CO_2 by green plants is light.

Photorespiration is the uptake of O_2 and release of CO_2 in light and results from the biosynthesis of glycolate in chloroplasts and subsequent metabolism of glycolate acid in the same leaf cell. Biochemical mechanism for photorespiration is also called glycolate metabolism.

Loss of energy occurs during this process. The process of photorespiration involves the involvement of chloroplasts, peroxysomes and mitochondria. RuBP carboxylase also catalyses another reaction which interferes with the successful functioning of Calvin cycle.

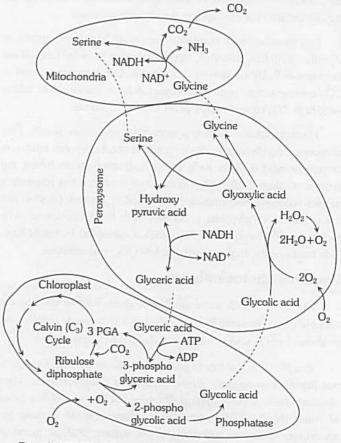

Fig: 4.3-10 The biochemical pathway of photorespiration

Biochemical mechanism

(1) Ribulose-1, 5-biphosphate $\xrightarrow{O_2}$

2 Phosphoglycolic acid +3 Phosphoglyceric acid

(2) 2 Phosphoglycolic acid + H_2O Phosphatase

Glycolic acid + Phosphoric acid.

(3) Glycolic acid + O_2 $\xrightarrow{\text{Glycolic acid}}$ Glyoxylic acid + H_2O_2

 $2H_2O_2 \xrightarrow{\text{Catalase}} 2H_2O + O_2$

(4) Glyoxylic acid + Glutamic acid Glutamate-glyoxylate transaminase

Glycine + a-keto glutaric acid

(5) 2 Glycine + H_2O + NAD^+ ------

Serine + CO₂ + NH₃ + NADH

(7) Glyceric acid + ATP → 3 phosphoglyceric acid

+ ADP + phosphate

Importance of photorespiration: Photorespiration is quite different from respiration as no ATP or NADH are produced. Moreover, the process is harmful to plants because as much as half the photosynthetically fixed carbon dioxide (in the form of RuBP) may be lost into the atmosphere through this process.

Any increase in O_2 concentration would favour the uptake of O_2 rather than CO_2 and thus, inhibit photosynthesis for this rubisco functions as RuBP oxygenase. Photorespiration is closely related to CO_2 compensation point and occurs only in those plants which have high CO_2 compensation point such as C_3 plants.

Photorespiration generally occurs in temperate plants. Few photorespiring plants are: Rice, bean, wheat, barley etc. Inhibitors of glycolic acid oxidase such as hydroxy sulphonates inhibit the process of photorespiration. Unlike usual mitochondria respiration neither reduced coenzymes are generated in photorespiration nor the oxidation of glycolate is coupled with the formation of ATP molecules. Photorespiration (C_2 cycle) is enhanced by bright light, high temperature, high oxygen and low CO_2 concentration.

Bacterial photosynthesis

Like green plants, some purple and green sulphur bacteria are capable of synthesizing their organic food in presence of light and in absence of O_2 , which is known as bacterial photosynthesis.

Van Niel was the first to point out these similarities. Oxygen is not liberated in bacteria during process of photosynthesis. Their photosynthesis is non-oxygenic. Because bacteria use H_2S in place of water (H_2O) as hydrogen donor. Photosynthetic bacteria are anaerobic. Only one type of pigment system (PSI) is found in bacteria except cyanobacteria which possess both PSI and PSII.

Bacteria has two type of photosynthetic pigments. Bacteriochlorophyll and Bacterioviridin. Bacteriochlorophyll differs from Chl. *a* in having one pyrrol ring with two hydrogen.

The photosynthetic bacteria fall under three categories

- (1) Green sulphur bacteria: It contains chlorobium chlorophyll, which absorb 720-750nm (far red light) of wavelength of light. e.g., Chlorobium.
 - (2) Purple sulphur bacteria: e.g., Chromatium.
- (3) Purple non-sulphur bacteria : e.g., Rhodospirillum, Rhodopseudomonas.

Characteristics of bacterial photosynthesis are :

- (1) No definite chloroplasts but contain simple structures having pigments called chromatophores (term coined by Schmitz).
 - (2) Contain chlorobium chlorophyll or bacterio-chlorophyll.
 - (3) Use longer wavelengths of light (720-950nm).
- (4) No utilization of H_2O (but use H_2S or other reduced organic and inorganic substances).
 - (5) No evolution of O2.
 - (6) Photoreductant is NADH2 (Not NADPH2).
- (7) Only one photoact and hence one pigment system and thus one reaction centre, i.e., P_{890} .
 - (8) Cyclic photophosphorylation is dominant.
 - (9) It occurs in presence of light and in absence of O2.

Chemosynthesis

Some forms of bacteria obtain energy by chemosynthesis. This process of carbohydrate formation in which organisms use chemical reactions to obtain energy from inorganic compounds is called chemosynthesis. Such chemoautotrophic bacteria do not require light and synthesize all organic cell requirements from CO_2 and H_2O and salts at the expense of oxidation of inorganic substances like $(H_2, NO_3^-, SO_4$ or carbonate). Some examples of chemosynthesis are :

- (1) **Nitrifying bacteria** : e.g., Nitrosomonas, Nitrosococcus, Nitrobacter etc.
- (2) **Sulphur bacteria** : e.g., Beggiatoa, Thiothrix and Thiobacillus.
- (3) Iron bacteria : e.g., Ferrobacillus, Leptothrix and Cladothrix.
 - (4) Hydrogen bacteria: e.g., Bacillus pentotrophus
- (5) Carbon bacteria : e.g., Carboxydomonas, Bacillus oligocarbophilus.

Factors affecting photosynthesis

Blackman's law of limiting factors

F.F. Blackman (1905) proposed the law of limiting factors according to which 'when process is conditioned to its rapidity by a number of factors, the rate of process is limited by the pace of the slowest factor'. CO_2 is usually a limiting factor in photosynthesis under field conditions particularly on clear summer days under adequate water supply.

Blackman's law of limiting factor is modification of Liebig's law of minimum, which states that rate of process controlled by several factors is only as rapid as the slowest factor permits. Theory of three cardinal points was given by Sachs in 1860. According to this concept, there is minimum, optimum and maximum for each factor. For every factor, there is a minimum value when photosynthesis starts, an optimum value showing highest rate and a maximum value, above which photosynthesis fails to take place.

Factors: The rate of photosynthetic process is affected by several external (Environmental) and internal factors.

External factors

- (1) **Light**: The ultimate source of light for photosynthesis in green plants is solar radiation, which moves in the form of electromagnetic waves. Out of the total solar energy reaching to the earth about 2% is used in photosynthesis and about 10% is used in other metabolic activities. Light varies in intensity, quality (Wavelength) and duration. The effect of light on photosynthesis can be studied under these three headings.
- (i) **Light intensity**: The total light perceived by a plant depends on its general form (*viz.*, height, size of leaves, etc.) and arrangement of leaves. Of the total light falling on a leaf, about 80% is absorbed, 10% is reflected and 10% is transmitted.

In general, rate of photosynthesis is more in intense light than diffused light. (Upto 10% light is utilized in sugarcane, i.e., Most efficient converter).

Another photosynthetic superstar of field growing plants is Oenothera claviformis (Winter evening-primrose), which utilizes about 8% light.

However, this light intensity varies from plant to plant, e.g., more in heliophytes (sun loving plants) and less in sciophytes (shade loving plants). For a complete plant, rate of photosynthesis increases with increase in light intensity, except very high light intensity where 'Solarization' phenomenon occurs, i.e., photo-oxidation of different cellular components including chlorophyll occurs.

It also affects the opening and closing of stomata thereby affecting the gaseous exchange. The value of light saturation at which further increase is not accompanied by an increase in CO_2 uptake is called light saturation point.

- (ii) **Light quality**: Photosynthetic pigments absorb visible part of the radiation *i.e.*, $380m\mu$ to $760m\mu$. For example, chlorophyll absorbs blue and red light. Usually plants show high rate of photosynthesis in the blue and red light. Maximum photosynthesis has been observed in red light than in blue light. The green light has minimum effect. On the other hand, red algae shows maximum photosynthesis in green light and brown algae in blue light.
- (iii) **Duration of light:** Longer duration of light period favours photosynthesis. Generally, if the plants get 10 to 12hrs light per day it favours good photosynthesis. Plants can actively exhibit photosynthesis under continuous light without being damaged. Rate of photosynthesis is independent of duration of light.

- (2) **Temperature**: The optimum temperature for photosynthesis is 20 to 35°C. If the temperature is increased too high, the rate of photosynthesis is also reduced by time factor which is due to denaturation of enzymes involved in the process. Photosynthesis occurs in some conifers at high altitudes at 35°C. Some algae in hot springs can undergo photosynthesis even at 75°C.
- (3) **Carbon dioxide**: Carbon dioxide present in the atmosphere is about 0.032% by volume and it is really a low concentration which acts as limiting factor in nature. If we increase the amount of CO_2 under laboratory conditions and if the light and temperature are not the limiting factors, the rate of photosynthesis increases. This increase is observed upto 1% of CO_2 concentration. At the same time very high concentration of CO_2 becomes toxic to plants and inhibits photosynthesis.
- (4) Water: Water is an essential raw material in photosynthesis. This rarely, acts as a limiting factor because less than 1% of the water absorbed by a plant is used in photosynthesis. However, lowering of photosynthesis has been observed if the plants are inadequately supplied with water.
- (5) Oxygen: Excess of O_2 may become inhibitory for the process. Enhanced supply of O_2 increases the rate of respiration simultaneously decreasing the rate of photosynthesis by the common intermediate substances. The concentration for oxygen in the atmosphere is about 21% by volume and it seldom fluctuates. O_2 is not a limiting factor of photosynthesis. An increase in oxygen concentration decreases photosynthesis and the phenomenon is called Warburg effect. (Reported by German scientist Warburg (1920) in Chlorella algae).

This is due to competitive inhibition of RuBP-carboxylase by increased O_2 levels, i.e., O_2 competes for active sites of RuBP-carboxylase enzyme with CO_2 . The explanation of this problem lies in the phenomenon of photorespiration. If the amount of oxygen in the atmosphere decreases then photosynthesis will increase in C_3 cycle and no change in C_4 cycle.

(6) Pollutants and Inhibitors: The oxides of nitrogen and hydrocarbons present in smoke react to form peroxyacetyl nitrate (PAN) and ozone. PAN is known to inhibit Hill reaction. Diquat and Paraquat (Commonly called as Viologens) block the transfer of electrons between Q and PQ in PS. II. Other inhibitors of photosynthesis are monouron or CMU (Chlorophenyl dimethyl urea) diuron or DCMU (Dichlorophenyl dimethyl urea), bromocil and atrazine etc. Which have the same mechanism of action as that of viologens.

At low light intensities potassium cyanide appears to have no inhibiting effect on photosynthesis.

(7) **Minerals**: Presence of Mn^{++} and Cl^- is essential for smooth operation of light reactions (Photolysis of water/evolution of oxygen) Mg^{++} , Cu^{++} and Fe^{++} ions are important for synthesis of chlorophyll.

Internal factors

 Protoplasmic factors: There is some unknown factor which affects the rate of photosynthesis.

These factors affect the dark reactions. The decline in the rate of photosynthesis at temperature above 30°C or at strong light intensities in many plants suggests the enzymatic nature of this unknown factor.

- (2) **Chlorophyll content :** Chlorophyll is an essential internal factor for photosynthesis. The amount of CO_2 fixed by a gram of chlorophyll in an hour is called photosynthetic number or assimilation number. It is usually constant for a plant species but rarely it varies. The assimilation number of variegated variety of a species was found to be higher than the green leaves variety.
- (3) Accumulation of end products: Accumulation of food in the chloroplasts reduces the rate of photosynthesis.
- (4) Structure of leaves: The amount of CO_2 that reaches the chloroplast depends on structural features of the leaves like the size, position and behaviour of the stomata and the amount of intercellular spaces. Some other characters like thickness of cuticle, epidermis, presence of epidermal hairs, amount of mesophyll tissue, etc., influence the intensity and quality of light reaching in the chloroplast.

- Photosynthetic materials: 264 gm of CO_2 and 216 gm of water give rise to 108 gm of water, 192 gm of O_2 and 180 gm of glucose.
- Rubisco: Rubisco constitutes 16% of chloroplast protein. It is the most abundant protein on this planet.
- Z T.W. Engelmann (1882) experimentally verified that in monochromatic lights, photosynthesis is maximum in red light.
- NADP (Nicotinamide adenine dinucleotide phosphate) was earlier called as TPN (Triphosphopyridine nucleotide),
- In green plants the hydrogen acceptor is NADP, but in bacteria it is NAD.
- No Emerson effect is seen in bacteria.
- Cytochromes: The terms was coined by Keilin (1925) though the biochemicals were discovered by Mac Munn (1866).
- Cytochrome proteins serving as electron carriers in respiration, photosynthesis and other oxidative reduction reactions.
- Intensity of light can be measured by Luxmeter.
- Isolated chlorophyll 'a' in pure form emits red colour. It is called fluoresence.
- In angiosperms, synthesis of chlorophyll occurs in presence of light.
- The precursor of chlorophyll is chlorophyllide.
- Chlorophyll term was coined by Pelletier and Coventou (1818) who also discovered the pigment.
- \not Hydrilla plant is used in an experiment commonly performed in laboratory in demonstrate evolution of O_2 in photosynthesis.

Ordinary Thinking

Objective Questions

History of photosynthesis

- The law of limiting factor for photosynthesis was enunciated by [NCERT; CMC Vellore 1994;

KCET 1994; Kerala PMT 2004, 06]

- (a) $6CO_2 + 6H_2O \xrightarrow{\text{Light}} C_2H_{12}O_6 + 6O_2$
- (b) $6CO_2 + 12H_2O \xrightarrow{\text{Light}} C_6H_{12}O_6 + 6H_2O + 6O_2$
- (c) $12CO_2 + 6H_2O \xrightarrow{\text{Light}} 2C_6H_{12}O_6 + 6O_2$
- (d) None of the above
- 10. Quantasomes are found in

[RPMT 1995]

- (a) Surface of cristae
- (b) Surface of plasma membrane
- (c) Surface of nuclear membrane
- (d) Surface of thylakoids
- 11. The full expansion of NADP is

[RPMT 1997]

- (a) Nicotinamide adenine diphosphate
 - (b) Nicotinamide adenosine diphosphate
 - (c) Nicotinamide adenine dinucleotide phosphate
 - (d) Nicotinamide adenosine dinucleotide phosphate
- Make suitable pair
 - (A) Emerson effect
- (a) C₄ cycle
- (B) Hill reaction
- (b) Photolysis
- (C) Calvin's cycle
- (c) C₃ cycle
- (D) Hatch and Slack cycle
- (d) Photosystem-I and II
 - [RPMT 1997]
- (a) Aa, Bb, Cc, Dd
- (b) Aa, Bc, Cd, Db
- (c) Ac, Bd, Ca, Db
- (d) Ad, Bb, Cc, Da
- Suspension of isolated thylakoids in culture medium containing CO₂ and H₂O does not produce hexose due to absence of which of the following [DPMT 2004]
 - (a) ATP
- (b) Enzyme
- (c) Proteins
- (d) Hill reagent

14. Match the sites in column I with the processes in column II and choose the correct combination from the options

	Column I		Column II
A.	Grana of chloroplast	1.	Kreb's cycle
B.	Stroma of chloroplast	2.	Light reaction
C.	Cytoplasm	3.	Dark reaction
D.	Mitochondrial matrix	4.	Glycolysis

[RPMT 1995; MP PMT 2000: Kerala PMT 2004]

(a) A-4, B-3, C-2, D-1

(b) A-1, B-2, C-4, D-3

(c) A-2, B-1, C-3, D-4

(d) A-3, B-4, C-1, D-2

(e) A-2, B-3, C-4, D-1

15. 85-90% of all photosynthesis of the world is carried out by [AMU (Med.) 2009]

Or

The maximum evolution of oxygen is by greatest producers of organic matter

- (a) Shrubs
- (b) Herbs
- (c) Oceanic algae/Phytoplanktons
- (d) Trees with large branches
- See the following diagram and identify X and Y with their 16.

	X		area is a mount	Y
	Structure	Function	Structure	Function
(a)	Grana	CO ₂ fixation	Lamellae	Photolysis of water
(b)	Stroma	Photolysis	Grana	CO ₂ fixation
(c)	Grana	CO ₂ fixation	Stroma	Photolysis of water
(d)	Grana	Photolysis of water	Stroma	CO ₂ fixation

- 17. In photosynthesis, energy from light reaction to dark reaction is transferred in the form of [CBSE PMT 2002]
 - (a) ADP
- (b) ATP
- (c) RUDP
- (d) Chlorophyll
- The synthesis of ATP in photosynthesis and respiration is essentially an oxidation-reduction process involving removal of energy from [CBSE PMT 1992; BHU 1994]

Or

Which one is always transferred in redox reaction

[Odisha JEE 2009]

- (a) Oxygen
- (b) Phytochrome
- (c) Cytochrome
- (d) Electrons
- In photosynthesis, plants
- [AFMC 2003; MP PMT 2004]
- (a) Absorb O2 and release CO2
 - (b) Absorb CO2 and release O2
 - (c) Absorb NH3 and release N2
 - (d) Absorb N2 and release NH3

- 20. Wavelength of green light is
 - (a) $400 450 \, m\mu$
- (b) 500 550 mu
- (c) 660 720 mu
- (d) 720 800 mu
- Chemosynthesis and photosynthesis are alike in that both
 - (a) Are associated with heterotroph
 - (b) Require sunlight as an energy source
 - (c) Methods of autotrophic nutrition
 - (d) Occur in tracheophytes
- 22. Ribulose diphosphate carboxylase oxygenase is located in
 - (a) Mitochondria
- (b) Chloroplasts
- (c) Peroxisomes
- (d) Golgi bodies
- 23. The percentage of light energy utilized for photosynthesis by higher plants is [Odisha JEE 2008]
 - (a) 100%
- (b) 50 %
- (c) 10%
- (d) 1 to 2%
- 24. During photosynthesis

[BHU 1995;

- CPMT 1998, 2003; Pb. PMT 2000, 03; RPMT 2005] (a) Both CO2 and water get oxidized
- (b) Both CO2 and water get reduced
- (c) Water is reduced and CO2 is oxidized
- (d) Carbon dioxide get reduced, water get oxidised and ATP is formed
- Intensity of light can be measured by
 - (a) Luxmeter
- (b) Wilmott's bubbler
- (c) Ganong's potometer
- (d) Farmer's potometer
- 26. Assimilatory power refers to

[AFMC 1994]

- (a) Generation of ATP and NADPH2
 - (b) Reduction of CO2
 - (c) Splitting of water
 - (d) Disintegration of plastids
- 27. Grana refers to
 - (a) Stacks of thylakoids in plastids of higher plants
 - (b) A constant in quantum equation
 - (c) Glycolysis of glucose
 - (d) Bye product of photosynthesis
- Intact chloroplast from green leaves can be isolated by 28.
 - (a) Acetone
- (b) Ethanol
- (c) Alcohol
- (d) Sugar solution
- Dimorphic chloroplasts are present in 29.

[MHCET 2002; WB JEE 2008, 10]

- (a) Sugarcane(C₄)
- (b) Cotton
- (c) Pea
- (d) Mango
- Phenomenon which converts light energy into chemical 30. [AFMC 2005]
 - (a) Respiration
- (b) Photosynthesis
- (c) Transpiration
- (d) None of these
- For the process of photosynthesis all except one of the following items are essential. Point out the exception
 - (a) Water, minerals
 - (b) Light, chlorophyll
 - (c) CO2, optimum temperature
 - (d) Oxygen, sucrose

32.	Plants are known as puris	iers of air due to process of	5.	Consider the following st

(e) B and D alone are correct

(b) Chlorophyll 'b'

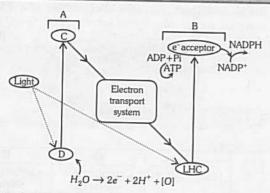

(d) Xanthophyll

(a) Chlorophyll 'a'

(c) Carotene

UNIVERSAL BOOK DEPOT 1960

11.

Which of the following is correctly labelled for the given figure [AIIMS 2012]

(a) A: PS II; B: PS I; C: e-acceptor; D: LHC

(b) A: LHC; B: e-acceptor; C: PS I; D: PS II

(c) A: PS I; B: PS II; C: e-acceptor; D: LHC

(d) A: e-acceptor; B: LHC; C: PS II; D: PS I

 Which of the following wavelength occur in red part of the spectrum

(a) 470 nm

(b) 390 nm

(c) 680 nm

(d) 830 nm

 Which of the following statement is true with regard to the light reaction of photosynthetic mechanism in plants

[Kerala PMT 2006]

- (a) Chlorophyll A occurs with peak absoption at 680 nm in photosystem I and at 700 nm in photosystem II.
- (b) Magnesium and sodium ions are associated with photolysis of water molecules.
- (c) O2 is evolved during cyclic photophosphorylation.
- (d) Photosystems I and II are both involved in non-cyclic photophosphorylation
- (e) Both ATP and NADPH₂ are formed during cyclic photophosphorylation
- 14. Excitation of chlorophyll due to light is a

[BHU 2012]

- (a) Photooxidation reaction (b) Endergonic reaction
- (c) Thermochemical reaction(d) Photochemical reaction
- The given diagram indicates the movement of substances into in and out of a chloroplast

What do labels 1 to 4 represent

INCER

King Cold Cold	100000 1 10 1	represent		INCER
MILE	1	2	3	4
(a)	Sugar	H ₂ O	ATP	O ₂
(b)	H ₂ O	O ₂	CO ₂	Sugar
(c)	CO ₂	H ₂ O	Sugars	O ₂
(d)	CO ₂	ATP	H ₂ O	Starch

16. Solarization is

[BHU 2005]

- (a) Formation of chlorophyll
- (b) Destruction of chlorophyll
- (c) Utilisation of sunlight
- (d) Effects of solar light
- 17. Which statement about photosynthesis is false [KCET 2009]
 - (a) The electron carriers involved in photophosphorylation are located on the thylakoid membranes
 - (b) Photosynthesis is a redox process in which water is oxidised and carbon dioxide is reduced
 - (c) The enzymes required for carbon fixation are located only in the grana of chloroplasts
 - (d) In green plants, both PS-I and PS-II are required for the formation of NADPH + H⁺
- 18. Which one of the following is not true about the light reactions of photosynthesis [Kerala PMT 2009]
 - (a) Light energy provides energy for the photolysis of water through excitation of the reaction centre of PS II
 - (b) The flow of electrons from water to NADP in non-cyclic electron transport produces one ATP
 - (c) Reactions of the two photosystems are needed for the reduction of NADP
 - (d) P_{680} and P_{700} are the reaction centres of PS I and PS II respectively
 - (e) NADPH is not produced in cyclic electron transport in light reactions
- 19. Which of the following is photophosphorylation

[WB JEE 2008]

- (a) Production of ATP from ADP
- (b) Production of NADP
- (c) Synthesis of ADP from ATP
- (d) Production of PGA
- In chlorophyll structure four pyrrole rings are united with Mg by their atoms of [AMU (Med.) 2009]

(a) N

(b) C

(c) H

(d) O

- The first acceptor of electrons from an excited chlorophyll molecule of photosystem II is [CBSE PMT 2007, 08]
 - (a) Cytochrome
 - (b) Iron-sulphur protein
 - (c) Ferredoxin
 - (d) Quinone

22. DCMU

[MP PMT 2007]

- (a) Inhibits PS-I
- (b) Inhibits PS-II
- (c) Destroy chloroplast
- (d) Inhibits oxidative phosphorylation

23. NADPH2 is generated through

[CBSE PMT 1997]

Ferredoxin is a component of

[CBSE PMT 1991]

- (a) Glycolysis
- (b) Photosystem-I
- (c) Photosystem-II
- (d) Anaerobic respiration
- Photolysis of each water molecule in light reaction will yield

[Kerala PMT 2007]

- (a) 2 electrons and 4 protons
- (b) 4 electrons and 4 protons
- (c) 4 electrons and 3 protons
- (d) 2 electrons and 2 protons
- (e) 1 electron and 2 protons
- Which of the following statements is true with regard to the 25. [Kerala PMT 2011] light reaction of photosynthesis
 - (a) In PS II the reaction centre chlorophyll a has an absorption peak at 700 nm, hence is called P 700
 - (b) In PS I the reaction centre chlorophyll a has an absorption maxima at 680 nm and is called P 680
 - (c) The splitting of water molecule is associated with PS I
 - (d) Photosystems I and II are involved in Z scheme
 - (e) Lamellae of the grana have PS I and PS II and stroma lamellae membranes have PS II only
- Which one of the following statements about the events of 26. noncyclic photophosphorylation is not correct

[KCET 2010; J & K CET 2012]

- (a) Only one photosystem participates
- (b) ATP and NADPH are produced
- (c) Photolysis of water takes place
- (d) O2 is released
- In which stage of photosynthesis, light is directly necessary 27.

[CPMT 1996]

- (a) For electron exitation
- (b) For reduction of CO2
- (c) For regulating photosystem
- (d) For cyclic photophosphorylation
- The source of O_2 liberated in photosynthesis in green plants is 28.

[CPMT 1994, 95; Bihar MDAT 1992; MP PMT 1999, 2002, 10, 12; RPMT 1999]

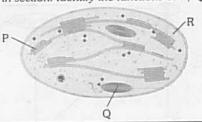

- (a) Photosynthetic enzyme
- (b) Carbohydrate present in leaf
- (c) Water
- (d) Carbon dioxide
- Photolysis of water takes place in

[CPMT 1995]

- (a) Calvin cycle
- (b) Glycolysis
- (c) Light phase
- (d) Dark phase
- The site of oxygen evolution and photosynthetic 30. phosphorylation in chloroplast are
 - (a) Matrix
- (b) Grana stacks
- (c) Inner wall of chloroplast (d) Surface of chloroplast
- The specific function of light energy in the process of photosynthesis is to
 - (a) Activate chlorophyll
- (b) Split water
- (c) Reduce carbon dioxide (d) Synthesize glucose

The given diagram shows the ultra structure of a chloroplast 32. as seen in section. Identify the functions of P, Q and R

[NCERT]

	P	Q	R
(a)	Light reaction	Carbohydrate synthesis	Carbohydrate storage
(b)	Light reaction	Carbohydrate storage	Carbohydrate synthesis
		Carbohydrate synthesis	Carbohydrate storage
(d)	Carbohydrate storage	Carbohydrate synthesis	Light reaction

- 33. NADP is converted into NADPH2 in
 - (a) Photosystem-I
 - (b) Non-cyclic photophosphorylation
 - (c) Calvin cycle
 - (d) Photosystem-II
- The creation of proton gradient across the thylakoid [AMU (Med.) 2010] membrane is a result of
 - (a) Decrease in proton number in stroma
 - (b) Accumulation of protons in the lumen
 - (c) Decrease in the pH in the lumen
 - (d) All of the above
- Read the following four statements. A, B, C and D and 35. select the right option having both correct statements.

Statements

- (A) Z scheme of light reaction takes place in presence of PS I only.
- (B) Only PS I is functional in cyclic photophosphorylation
- (C) Cyclic photophosphorylation results into synthesis of ATP and NADPH,
- (D) Stroma lamellae lack PS II as well as NADP

Options

[CBSE PMT (Mains) 2010]

- (a) (B) and (D)
- (b) (A) and (B)
- (c) (B) and (C)
- (d) (C) and (D)
- 36. Phtosynthetic unit is
- [MP PMT 2003]
- (a) Glyoxysome
- (b) Spherosome
- (c) Microsome
- (d) Quantasome
- P₇₀₀ is a special form of which pigment
- [RPMT 1997]
 - (a) Chlorophyll b
- (b) Carotenes
- (c) Chlorophyll a
- (d) Phycobilins
- Water soluble pigments found in plant cell vacuoles are

[CPMT 1994; BVP 2000; WB JEE 2011; BHU 2012; NEET (Phase-I) 2016]

- (a) Chlorophyll
- (b) Carotene
- (c) Anthocyanin/phycobilin (d) Xanthophyll

UNIVERSAL BOOK DEPOT 1960

39. Where does the primary photochemical reaction occur in chloroplast or Where does the light reactions of photosynthesis take place or Light reaction takes place in

[CPMT 1995, 98; RPMT 1995, 99; MP PMT 1999; Pb. PMT 1999, 2000]

- (a) Stroma
- (b) Endoplasmic reticulum
- (c) Quantasome or thylakoids (Grana)
- (d) Inner membrane of chloroplast
- 40. The trapping centre of light energy in photosystem-I is

[BHU 2000; BVP 2003]

Or

Pigment system—I receives radiant energy and releases electron [MP PMT 1992]

- (a) P-660
- (b) P-680
- (c) P-700
- (d) P-720
- 41. Blue-green algae shows
 - (a) Chlorophyll 'a'
- (b) Chlorophyll 'b'
- (c) Both (a) and (b)
- (d) None of the above
- Pigment system–I conducts

[Odisha JEE 2011]

- (a) Cyclic photophosphorylation
 - (b) Non-cyclic photophosphorylation
 - (c) Both (a) and (b)
 - (d) None of the above
- 43. Pigment system-II is concerned with

[MHCET 2000; BHU 2003]

- (a) Photolysis of water
- (b) Reduction of CO2
- (c) Flowering
- (d) None of the above
- 44. The role of chlorophyll in photosynthesis is

[CBSE PMT 2002]

- (a) Absorption of CO2
- (b) Absorption of light
- (c) Absorption of light and photochemical decomposition of water
- (d) Absorption of water
- 45. Photophosphorylation is a process in which [MP PMT 1996]
 - (a) Light energy is converted into chemical energy in the form of ATP
 - (b) NADP is formed
 - (c) Chemical energy is used to produce ATP
 - (d) CO2 is reduced to carbohydrate
- 46. Which one of the following statements about cytochrome P₄₅₀ is wrong [CBSE PMT 1998]
 - (a) It has an important role in metabolism
 - (b) It contains iron
 - (c) It is a coloured cell
 - (d) It is an enzyme involved in oxidation reactions
- 47. Chlorophyll is present
 - (a) On the surface of chloroplast
 - (b) In the stroma of chloroplast
 - (c) In the grana of chloroplast
 - (d) Dispersed throughout the chloroplast

- 48. Through which of the following substances the photosystem-I passes an electron to NADP during light reactions
 - (a) Plastocyanin
- (b) Plastoquinone
- (c) Cytochrome
- (d) Ferredoxin
- During photochemical reactions of photosynthesis [NCERT;
 RPMT 1999; KCET 1994; MDAT 1995]
 - (a) Liberation of oxygen takes place
 - (b) Formation of ATP and NADPH2 take place
 - (c) Liberation of O₂ and formation of ATP and NADPH₂ take place
 - (d) Assimilation of CO2 takes place
- 50. The core metal of chlorophyll is

[CBSE PMT 1997, 99; AFMC 1999; CPMT 2005]

Which element is left when chlorophyll is burnt [CPMT 1993]

(a) Fe

(b) Mg

- (c) Ni
- (d) Cu
- 51. Hill's reaction takes place in
 - (a) Dark
- (b) Light
- (c) Dark and light both
- (d) At any time
- 52. In photosynthesis light energy is utilized in

[Bihar MDAT 1995; CPMT 1998; MHCET 2003; Odisha JEE 2005]

- (a) Converting ATP into ADP
- (b) Changing CO2 into carbohydrate
- (c) Converting ADP into ATP
- (d) All of the above
- Main pigment involved in transfer of electrons in photosynthesis is [CPMT 1998]
 - (a) Cytochrome
- (b) Phytochrome
- (c) Both (a) and (b)
- (d) None of these
- 54. ATP is produced during
- [MH CET 2004; MP PMT 2005; CBSE PMT 2009]
- (a) Cyclic photosphosphorylation
- (b) Non cyclic photosphosphorylation
- (c) Both
- (d) None
- 55. Splitting of water in photosynthesis is called

[Pb. PMT 2000, 04; MHCET 2001]

- (a) Dark reaction
- (b) Electron transfer
- (c) Photolysis
- (d) Phototropism
- **56.** Chlorophyll is
- [MP PMT 1996; BVP 2002]
- (a) Soluble in organic solvents
- (b) Soluble in water
- (c) Soluble in both organic solvents and water
- (d) None of the above
- In noncyclic photophosphorylation, the pigment molecule first excited is [MHCET 2004]
 - (a) P_{680}
- (b) P₇₀₀
- (c) Chlorophyll-b
- (d) Xanthophyll
- 58. The 'Z' scheme of photosynthesis was proposed by
 - (a) Hill and Bendall
 - (b) Emerson
 - (c) Arnon
 - (d) Rabinowitch and Govindjee

64.	Which one of the following elements is required for		(c) 600 nm (d) 660 nm
	photosynthetic oxygen evolution [MP PMT 1998; AMU (Med.) 2012]	76.	light harvesting complex are [Odisha JEE 2005]
	(a) Copper (b) Iron		(a) 100 (b) 200
	(c) Manganese (d) Zinc		(c) 400 (d) 500
65.	Photolysis of water by isolated chloroplasts was demonstrated by [AIEEE Pharmacy 2004]	77.	Photosystem I and Photosystem II are found in [CBSE PMT 1992; RPMT 1999; BHU 2001; MP PMT 2001]
	(a) Robin Hill (b) Van Niel		(a) Stroma of chloroplast
	(c) Liebig (d) Calvin		(b) Grana of chloroplast
66.	Photosynthetically active radiation (PAR) represents the		(c) Matrix of mitochondria
	following range of wavelength		(d) Inner membrane of mitochondria
	[CBSE PMT 1996, 2005; AIIMS 2007; BHU 2012] (a) 340–450 mm (b) 400–700 mm	78.	are primarily absorbed by carotenoids of the higher plants
	(c) 500–600 mm (d) 450–950 mm		[CBSE PMT 1999]
67.	Plants adapted to low light intensity have [CBSE PMT 2004]		(a) Violet and blue (b) Blue and green (c) Green and red (d) Red and violet
	(a) More extended root system	70	
	(b) Leaves modified to spines	79.	(a) Blue region [NCERT]
	(c) Larger photosynthetic unit size than the sun plants		(b) Red region
	(d) Higher rate of CO ₂ fixation than the sun plants		(c) Blue and red regions
68.	Hill reaction occurs in [AIIMS 2003]		(d) Yellow and violet regions
	(a) High altitude plants (b) Total darkness	80.	
	(c) Absence of water (d) Presence of ferredoxin		1
69.	ATP formation in photosynthesis is known as [MP PMT 1993, 2006; CPMT 1998]		TO THE REPORT OF THE PERSON OF
	(a) Phosphorylation		Q 2H ₂ O< 4e ⁻
	(b) Photophosphorylation		4H++00
	(c) Oxidative phosphorylation		cyto f
	(d) None of the above		PS II (P680) PS I
70.	In photosystem-I, the first electron acceptor is [CBSE PMT 2006]		In the above schematic diagram, which is plastocyanin [KCET 2007]

(b) An iron-sulphur protein

(d) Cytochrome

(b) D

(d) B

(a) C

(c) A

(a) Plastocyanin

(c) Ferredoxin

UNIVERSAL

- How chlorophyll would appear when seen in red light
 - (a) Red
- (b) Green
- (c) Black (d) Colourless
- Which one of the following concerns photophosphorylation 82. [CBSE PMT 1999]
 - (a) AMP + Inorganic PO₄ Light energy → ATP
 - (b) ADP + AMP Light energy ATP
 - (c) ADP + Inorganic PO₄ Light energy ATP
 - (d) ADP + Inorganic PO₄ → ATP
- 83. Who revealed the chemical composition of chlorophyll carotene and xanthophyll
 - (a) Govindiee
- (b) Willstatter and Stoll
- (c) Park and Biggins
- (d) Meyers and French
- Which one is Cu++ containing pigment

[CPMT 1999, 2003; MP PMT 2003]

- (a) Ferredoxin
- (b) Plastocyanin
- (c) Plastoquinone
- (d) Cytochrome
- The chlorophylls absorb visible light in the region of 85. following wavelengths [BHU 1994]
 - (a) 400 nm to 500 nm only
 - (b) 600 nm to 800 nm only
 - (c) 400 nm to 500 nm and 600 nm to 700 nm
 - (d) 300 nm to 400 nm only

Dark reaction

- Dark reaction of photosynthesis is called 1.
 - (a) Aphotic action
- (b) Black action
- (c) Blackman's reaction
 - (d) None of the above
- 2. The Calvin cycle proceeds in three stages
 - 1. Reduction, during which carbohydrate is formed at the expense of the photochemically made ATP and NADPH
 - 2. Regeneration, during which the carbon dioxide acceptor ribulose-1, 5-biphosphate is formed
 - 3. Carboxylation, during which carbon dioxide combines with ribulose-1, 5-biphosphate

Identify the correct sequence

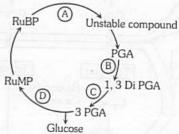

[Kerala PMT 2006]

- (a) 3-1-2
- (b) 3-2
- (c) 1-2-3
- (d) 2-1-3
- (e) 1-3-2
- PGA as the first CO2 fixation product was discovered in 3. photosynthesis of [CBSE PMT (Pre.) 2010]
 - (a) Alga
- (b) Bryophyte
- (c) Gymnosperm
- (d) Angiosperm
- Identify the incorrect statement with respect to Calvin cycle

[KCET 2009]

- (a) The carboxylation of RuBP is catalysed by rubisco
- (b) The first stable intermediate compound formed is phosphoglycerate
- 18 molecules of ATP are synthesized during carbon (c) fixation
- (d) $NADPH + H^+$ produced in light reaction is used to reduce diphosphoglycerate

- The enzyme responsible for primary carboxylation in C₃ 5 plants is [Kerala PMT 2009]
 - (a) Hexokinase
 - Succinic dehydrogenase (b)
 - (c) Pyruvate carboxylase
 - (d) RuBP carboxylase oxygenase
 - (e) PEP carboxylase
- In a condensed schematic representation of dark reaction of photosynthesis given below, steps are indicated by alphabets. Select the option where the alphabets are correctly identified

[KCET 2012]

- (a) A = CO₂ fixation, B = Reduction, C = Phosphorylation, D = Regeneration
- (b) A = Regeneration, B = CO₂ fixation, C = Reduction, D = Phosphorylation
- (c) $A = CO_2$ fixation, B = Phosphorylation, C = Reduction, D = Regeneration
- (d) A = CO₂ fixation, B = Phosphorylation, C = Regeneration, D = Reduction
- If bundlesheath cells of the C4 plants are infected by an 7. organism, which utilize CO2 efficiently then which process will be affected very first [GUJCET 2014]
 - (a) PGAL → RUBP
 - (b) PGAL + PGA → Glucose
 - (c) PGA → PGAL
 - (d) RUBP → PGA
- For the same amount of CO_2 fixed, a C_4 plant, in comparison with a C_3 plant, loses only [AMU (Med.) 2009,10]
 - (a) Half amount of water
- (b) Equal amount of water
- (c) Double amount of water (d) None of these
- Which of the following is the main product in the 9. photorespiration of C3 plants

[CPMT 1999; MP PMT 2010, 12]

- (a) Phosphoglycerate (b) Phosphoglycolate
- (c) Glycerate
 - (d) Glycolate
- During Calvin cycle the total number of CO2, ATP and 10. NADPH molecules utilized and glucose, ADP and NADP molecules generated is [AMU (Med.) 2012]
 - (a) 31

(b) 36

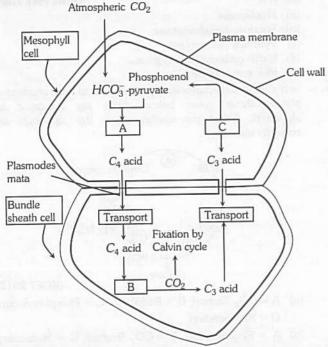

- (c) 61
- (d) 67
- CO2 joins the photosynthetic pathway during

[MP PMT 1999]

- (a) Light reaction
- (b) Dark reaction
- (c) Photosystem-I (d) Photosystem-II

12. Study the pathway given below

In which of the following options correct words for all the three blanks A, B and C are indicated

INCERT. CRSE PMT (Mains) 20101

		INCLINI, CBGETTIT (TIME)				
	A	В	C			
(a)	Decarboxylation	Reduction	Regeneration			
(b)	Fixation	Transamination	Regeneration			
(c)	Fixation	Decarboxylation	Regeneration			
(d)	Carboxylation	Decarboxylation	Reduction			

- The initial enzyme of Calvin cycle is
- [VITEEE 2008]
- (a) Ribulose 1, 5-diphosphate carboxylase
- (b) Triose phosphate dehydrogenase
- (c) Phosphopentokinase
- (d) Cytochrome oxidase
- 14. During photosynthesis when PGA is changed into phosphoglyceraldehyde, which of the following reaction occur
 - (a) Oxidation
- (b) Reduction
- (c) Electrolysis
- (d) Hydrolysis
- 15. Ribulose diphosphate carboxylase enzyme catalyses the carboxylation reaction between [MP PMT 2013]
 - (a) Oxaloacetic acid and acetyl CoA
 - (b) CO2 and ribulose 1, 5 diphosphate
 - (c) Ribulose diphosphate and phosphoglyceraldehyde
 - (d) PGA and dihydroxy acetone phosphate
- 16. Calvin cycle occur in
- [MP PMT 1996; BVP 2002]
- (a) Chloroplasts
- (b) Cytoplasm
- (c) Mitochondria
- (d) Glyoxysomes
- 17. During dark reaction of photosynthesis
 - (a) Water split
 - (b) CO2 is reduced to organic compounds
 - (c) Chlorophyll is activated
 - (d) 6 carbon sugar is broken down into 3 carbon sugar

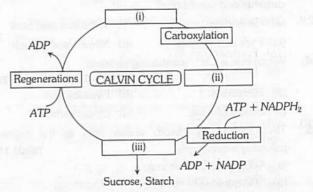

18. 3-PGA is first stable product in

IDPMT 2007

- (a) Carbon-reduction cycle (b) OAA
- (c) Malic acid
- (d) PEP
- In C₃ plants, the first stable product of photosynthesis during dark reaction is

[CPMT 1992, 2009; BHU 1995; RPMT 1995; CBSE PMT 1995; KCET 1998; MP PMT 2000, 06; BVP 2000, 09; DPMT 2006; Kerala PMT 2009]

- (a) 3-phosphoglyceric acid (b) Phosphoglyceraldehyde
- (c) Malic acid
- (d) Oxaloacetic acid
- **20.** Choose the correct combinations of labelling the carbohydrate molecule involved in the Calvin cycle.

[NCERT; Kerala PMT 2007]

- (a) (i) RuBP (ii) Triose phosphate (iii) PGA
- (b) (i) PGA (ii) RuBP (iii) Triose phosphate
- (c) (i) PGA (ii) Triose phosphate (iii) RuBP
- (d) (i) RuBP (ii) PGA (iii) Triose phosphate
- (e) (i) Triose phosphate (ii) PGA (iii) RuBP
- 21. One molecule of glucose in Calvin cycle is formed from

[KCET 2006; Odisha JEE 2010]

- (a) $6CO_2 + 12ATP$
- (b) 6CO2 + 30ATP + 12NADPH
- (c) 6CO₂ + 18ATP + 12NADPH
- (d) 6CO₂ + 18ATP + 30NADPH
- 22. Calvin cycle is
- [CPMT 1995]
- (a) Dependent on light
- (b) Not dependent on light
- (c) Occurs in light
- (d) None of these
- 23. How many Calvin cycle form one hexose molecule

[CBSE PMT 1996, 2000]

(a) 2

(b) 6

- (c) 4
- (d) 8
- 24. CO_2 acceptor in C_3 plants is [CBSE PMT 1995, 96,99; CPMT 1999, 2001; RPMT 2002, 06; J & K CET 2008; WB JEE 2009; AFMC 2010]
 - (a) Xylulose-5-phosphate
 - (b) 3-phosphoglyceric acid
 - (c) Ribulose 1, 5-diphosphate
 - (d) Phosphoenol pyruvic acid
- 25. Which of the following is present in Calvin cycle

[CBSE PMT 1996; AFMC 2008]

- (a) Photophosphorylation
- (b) Oxidative carboxylation
- (c) Reductive carboxylation
- (d) Oxidative phosphorylation

			Photosynthesis in Higher Plants 6// UNIVERSAL BOOK DEPOT 1960
26.	In C ₃ plants, photosynthesis occur in [J & K CET 2010]	4.	In C_4 plants, the bundle sheath cells
	(a) Bundles sheath cells (b) Peroxisome		[DUMET 2009; NEET (Karnataka) 2013]
	(c) Mesophyll cells (d) Kranz anatomy		(a) Have thin walls of facilitate the gaseous exchange
27.	In which plant Calvin experimented by radioactive isotopy		(b) Have large intercellular spaces
	to discover the stable product of C ₃ cycle [Odisha JEE 2005]		(c) Are rich in PEP carboxylase
	(a) Chlorella (b) Cycas		(d) Have a high density of chloroplasts and rich in RuBisCo
	(c) Carrot (d) Tobacco	5.	
28.	Radioactive C^{14} is given to CO_2 and released to atmosphere.		having -NH2 group formed in photosynthetic oxidation
	This CO ₂ is taken by RuBP in a C ₃ plant. First radioactive		cycle is [EAMCET 2009]
	C^{14} is seen in which compound [Manipal 2005]		(a) 1:1 (b) 2:1 (c) 3:2 (d) 3:4
	(a) PGAL (b) PEP	6.	
	(c) RMP (d) PGA	o.	The first carbon fixation in C_4 pathway occurs in chloroplasts of [CBSE PMT 1995;
29.	The first step in dark reaction of photosynthesis is		MP PMT 1997; WB JEE 2008]
	[CPMT 2004]		(a) Guard cells (b) Mesophyll cells
	(a) Formation of ATP		(c) Bundle sheath cells (d) Epidermal cells
	(b) Ionization of water	7.	An alternate CO2 fixation mechanism was found some
	(c) Attachment of CO ₂ to a pentose sugar		tropical species of grass family by Hatch and Slack, who
	(d) Excitement of electron of chlorophyll by a photon of light		were from [AMU (Med.) 2009]
30.	Which of the following is the first compound that accepts		(a) England (b) USA
	carbon dioxide during dark phase of photosynthesis		(c) Australia (d) New Zealand
	(a) NADP (b) RuBP	8.	In a CAM plant the concentration of organic acid
	(c) Ferridoxin (d) Cytochrome		[WB JEE 2009]
31.	Number of carboxylation occur in Calvin cycle, is		(a) Increases during the day
	[DPMT 2004]		(b) Decreases or increases during the day
	(a) 0 (b) 1 (c) 2 (d) 3		(c) Increases during night
32.	(c) 2 (d) 3 Reducing power which is transferred from light reaction of		(d) Decreases during any time
	photosynthesis to the dark reaction is [AFMC 2012]	9.	In photorespiration, what is the role of peroxisome
	(a) ATP (b) NADPH		[GUJCET 2007]
	(c) NADH (d) FADH ₂		(a) Help in oxidation of glycolate
	C₄/CAM/Photorespiration		(b) Help in oxygenation of glycolate
1.	The family in which many plants are C_4 type		(c) Help in synthesis of PGA
	(a) Malvaceae (b) Solanaceae		(d) Help in reduction of glyoxylate
	(c) Crucifereae (d) Gramineae	10.	During photorespiration, the oxygen consuming reaction (s)
2.	Which of the following statements with regard to		occur in [CBSE PMT 2006]
	photosynthesis is/are correct		(a) Grana of chloroplasts and peroxisomes
	A. In C_4 plants, the primary CO_2 acceptor is PEP		(b) Stroma of chloroplasts
	B. In the photosynthetic process PS II absorbs energy at or		(c) Stroma of chloroplasts and mitochondria
	just below 680 nm		(d) Stroma of chloroplasts and peroxisomes
	C. The pigment that is present in the pigment system I is	11.	
	P ₆₈₃ [Kerala PMT 2008]	11.	The energy wastage occurs during
	(a) B and C only (b) A only		(a) Dark respiration (b) Photosynthesis
	(c) C only (d) A and B only		(c) Glycolysis (d) Photorespiration
	(e) A and C only	12.	are CAM plant [Odisha JEE 2005; KCET 2011]
3.	The C ₄ plants are photosynthetically more efficient than C ₃		(a) Maize, papaya (b) Pineapple, agave
	plants because		(c) Onion, mango (d) Pea, sugarcane
	[CBSE PMT 2008; CBSE PMT (Pre.) 2010; AIIMS 2011]	13.	Which one is a C_4 plant [MP PMT 1993, 95; VITEE 2006]
	(a) The CO ₂ efflux is not prevented		(a) Sorghum (b) Tribulus
	(b) They have more chloroplasts		(c) Maize (d) All of these
	(c) The CO ₂ compensation point is more	14.	Photorespiration shows formation of [AIIMS 2012]
	(d) CO2 generated during photorespiration is trapped and		(a) Sugar but not ATP (b) ATP but not sugar

recycled through PEP carboxylase

(c) Both ATP and sugar

(b) ATP but not sugar

(d) Neither ATP nor sugar

In C4 plants, Calvin cycle occurs in

[CBSE PMT 1994; CPMT 2005]

- (a) Stroma of bundle sheath chloroplast
- (b) Mesophyll chloroplast
- (c) Grana of bundle sheath chloroplast
- (d) Does not occur as CO2 is fixed mainly by PEP and no CO2 is left for Calvin cycle
- 16. Photorespiration is characteristic of

[MP PMT 1994; BHU 1995, 2002]

- (a) CAM Plants
- (b) C3 Plants
- (c) C4 Plants
- (d) None of the above
- C4 photosynthesis does not occur in

[CPMT 1994; MP PMT 2000]

- (a) Zea mays
- (b) Saccharum munja
- (c) Saccharum officinarum
- (d) Euphorbia splendens
- Which of the following is CO_2 acceptor in C_4 plants

[NCERT; CBSE PMT 1990; CPMT 1994, 98, 2004, 09; BHU 1994, 2000, 01; EAMCET 1995; MP PMT 1996; Odisha PMT 2002; BVP 2002; MHCET 2002; RPMT 2006; Kerala PMT 2007; J & K CET 2010; NEET 2017]

- (a) Phosphoenol pyruvate (PEP)
- (b) Ribulose 1, 5-diphosphate (RuDP)
- (c) Oxaloacetic acid (OAA)
- (d) Phosphoglyceric acid (PGA)
- Which of the following cycle shows oxaloacetic acid as first [BHU 2008; J & K CET 2012]
 - (a) Calvin cycle
- (b) Hatch and Slack cycle (Ca)
- (c) C2 cycle
- (d) None of the above
- [CBSE PMT 1990; 20. Kranz type of anatomy is found in RPMT 1995, 97; MH CET 2006; J & K CET 2008;

AFMC 2009; CBSE PMT (Mains) 2010;

AIIMS 2012; WB JEE 2016]

- (a) C2 plants
- (b) C₃ plants
- (c) C₄ plants (Sugarcane) (d) CAM plants
- During photorespiration which compounds are formed having 2C and 3C respectively in Peroxisome

[GUJCET 2015]

- (a) Glycolate, Glycine
- (b) Glycine, Glycerate
- (c) Serine, Glycine
- (d) Phosphoglycerate, Glycolate
- 22. C4 plants are adapted to
- [NCERT; BHU 2002]
- (a) Hot and dry climate
- (b) Temperate climate
- (c) Cold and dry climate
- (d) Hot and humid climate
- Which one of the following is wrong in relation to photorespiration [CBSE PMT 2003]
 - (a) It is a characteristic of C3 plants
 - (b) It occurs in chloroplasts
 - (c) It occurs in day time only
 - (d) It is a characteristic of C₄ plants

A plant in your garden avoids photorespiratory losses, has improved water use efficiency shows high rates of photosynthesis at high temperatures and has improved efficiency of nitrogen utilisation. In which of the following physiological groups would you assign this plant

[NEET (Phase-I) 2016]

(a) C₃

- (c) CAM
- (d) Nitrogen fixer
- Which one of the following is a CAM plant [MHCET 2015]
 - (a) Maize
- (b) Kalanchoe
- (c) Sugarcane
- (d) Jowar
- 26. Select the incorrect matched pair with regard to C4 cycle

[Kera	a	PM	T	20	1	1

			fractum r r.r. morr
(a)	Primary CO ₂ fixation product	918	PGA
(b)	Site of initial carboxylation	- 8	Mesophyll cells
(c)	Primary CO ₂ acceptor	-	PEP
(d)	C ₄ plant	- 10	Maize
(e)	Location of enzyme RuBisCO	-	Bundle sheath cells
	-1076/1076/1076B)		

- CAM helps the plants in 27.
- [CBSE PMT (Pre.) 2011]
- (a) Reproduction
- (b) Conserving water
- (c) Secondary growth
- (d) Disease resistance
- 28. Agranal chloroplasts occur in certain [MP PMT 1995, 98]

Atriplex spongiosa is a

- (a) Succulents
- (b) C₄ plants
- (c) Hydrophytes
- (d) C₃ plants
- In the leaves of C4 plants, malic acid formation during CO2 29. fixation occurs in the cells of [CBSE PMT 2007, 08]
 - (a) Mesophyll
- (b) Bundle Sheath
- (c) Phloem
- (d) Epidermis
- 30. Which of the following plants stand intermediate between C₃ and C4 plants
 - (a) Triticum aestivum
- (b) Zea mays
- (c) Panicum milioides
- (d) All the above
- Chloroplasts without grana are known to occur in

[KCET 2006]

- (a) Bundle sheath cells of C3 plants
- (b) Mesophyll cells of C4 plants
- (c) Bundle sheath cells of C4 plants
- (d) Mesophyll cells of all plants.
- Which crop utilises solar energy most efficiently [BHU 2006] 32.
 - (a) Potato
- (b) Sugarcane
- (c) Wheat
- (d) Rice
- In maximum plants stomata open during day and closed in night. Its exception is [Pb. PMT 2004; AMU (Med.) 2005]
 - (a) Crassulacean acid metabolism plants
 - (b) C₃ plants
 - (c) Ca plants
 - (d) None of these

UNIVERSAL BOOK DEPOT 1960

			Priocosynthesis in righer Plants 0/9 UNIVERSAL BOOK DEPOT 1960
34.	Correlation between 'Kranz' anatomy and C4 path of CO2	44.	Which of the following statements regarding C_4 pathway is
	assimilation was first established by		false [Kerala PMT 2010, 12]
	(a) Hill and Bendall (b) Calvin		(a) The primary CO_2 acceptor is 5 carbon molecule
35.	(c) Dowton and Treguna (d) Arnold		
55.	The glycolate metabolism occur in [MP PMT 1995, 2000, 01; RPMT 1999; BHU 2001;		(b) The enzyme responsible for CO_2 fixation is PEP case
	AIIMS 2001; BVP 2003; WB JEE 2010]		(c) The mesophyll cell lack RuBisCO enzyme
	(a) Lysosomes (b) Ribosomes		(d) The C_4 acid OAA is formed in the mesophyll cells
	(c) Glyoxysomes (d) Peroxisomes		(e) The bundle sheath cells contain the enzyme PEP case
36.	Members of family Crassulaceae perform [MHCET 2004]	45.	CAM photosynthesis occurs in plants with [MP PMT 1993]
	(a) C_3 photosynthesis (b) CAM photosynthesis		(a) Thin green leaves with reticulate venation
	(c) C_4 photosynthesis (d) All of the above		(b) Thin green leaves with parallel venation
37.	In Kranz anatomy, the bundle sheath cells have		(c) Fleshy green leaves
	[CBSE PMT (Mains) 2011]		(d) Thin coloured leaves
	(a) Thin walls, no intercellular spaces and several	46.	A ALCOHOLOGICAL CONTROL OF THE CONTROL OF THE
	chloroplasts	10.	
	(b) Thick walls, many intercellular spaces and few		(a) Low CO ₂ concentration (b) Low temperature
	chloroplasts		(c) High O ₂ concentration (d) At low water
	 (c) Thin walls, many intercellular spaces and no chloroplasts 	47.	i - z - mane dela, in winett
	(d) Thick walls, no intercellular spaces and large number of		the enzyme that fixes CO_2 is [CBSE PMT 1999]
	chloroplasts		(a) Fructose phosphatase
38.	Source of CO ₂ for photosynthesis during day in CAM plant is		(b) Ribulose biphosphate carboxylase
	[CPMT 2005]		(c) Phosphoenol pyruvic acid carboxylase
	(a) 3-PGA (b) Malic acid		(d) Ribulose phosphate kinase
	(c) Oxalo-acetic acid (d) Pyruvate	48.	A process that makes important difference between C_3 and
39.	Which of the following is a 4-carbon compound		C ₄ plants is [CBSE PMT (Pre.) 2012; NEET (Phase-II) 2016]
	[Kerala PMT 2010]		(a) Transpiration (b) Glycolysis
	(a) Oxaloacetic acid (b) Phosphoglyceric acid		
	(c) Ribulose bis phosphate (d) Phosphoenol pyruvate (e) Citric acid	49.	
10.			Which of the statements is not true of the C_4 pathway [AIEEE Pharmacy 2004]
ıv.	Sugarcane show high efficiency of CO ₂ fixation because of		(a) It requires more energy than the C_3 pathway for
	(a) Calvin cycle (b) Hatch and Slack cycle		production of glucose
	(a) Calvin cycle (b) Hatch and Slack cycle (c) TCA cycle (d) Greater sunlight		(b) It overcomes loss due to photorespiration
11.	In C_4 -plants, the carbon dioxide fixation occurs in		(c) The CO_2 acceptor is a C_3 compound
			(d) It is inhibited by high CO_2 concentration
	(a) Guard cells (b) Spongy cells	50.	Photorespiration is called
	(c) Palisade cells (d) Bundle sheath cells		[MHCET 2000; VITEEE 2006; J & K CET 2010]
2.	Photorespiration is favoured by		(a) C_2 cycle (b) C_3 cycle
	[CBSE PMT 1991; BHU 2002; BVP 2003]		(c) C ₄ cycle (d) None of these
	(a) Low light and high O ₂	51.	The first reaction in photorespiraton is
	(b) Low O ₂ and high CO ₂		[RPMT 1999; CBSE PMT 2000; CPMT 2001]
	(c) Low temperature and high O ₂		(a) Carboxylation
	(d) High O ₂ and low CO ₂		(b) Decarboxylation
3.	Photosynthesis in C_4 plants is relatively less limited by		(c) Oxygenation
	atmospheric CO ₂ levels because [CBSE PMT 2005]		(d) Phosphorylation
	(a) Four carbon acids are the primary initial CO2 fixation	52.	In photorespiration glycolate is converted to CO_2 and serine in
	products		[AIEEE Pharmacy 2003]
	(b) The primary fixation of CO2 is mediated via PEP		(a) Chloroplasts (b) Peroxisomes
	carboxylase		(c) Vacuoles (d) Mitochondria
	(c) Effective pumping of CO ₂ into bundlesheath cells	53.	No. of carboxylation in C_4 cycle is/are [DPMT 2003]
	(d) Rubisco in C ₄ plants has higher affinity for CO ₂		(a) 1 (b) 2
	1. 3 3 3		(c) 5 (d) 3

54. In Hatch and Slack pathway **IBHU 20031** (a) Chloroplast are of same type (b) Occurs in Kranz anatomy where mesophyll have small chloroplast whereas bundle sheath have agranal chloroplast (c) Occurs in Kranz anatomy when mesophyll have small chloroplast where a bundle sheath have larger chloroplast (d) Kranz anatomy where mesophyll cell are diffused **55.** The enzyme which catalyzes the photosynthetic C_4 cycle is In C4 plants, CO2 combine with PEP in presence of (a) RuDP carboxylase (b) PEP carboxylase (d) None of these (c) Carbonic anhydrase Peroxysomes are found in [Odisha JEE 2005] 56. (a) Bundle sheath (b) Endosperm (c) Mesophyll cells (d) Vascular bundle Peroxysome are related with [PUNE CET 1998; 57. MP PMT 1998, 04, 05; AMU (Med.) 2005] (a) Photosynthesis (b) Photorespiration (c) Respiration (d) None Photorespiration takes place is 58. [BHU 1994, 2000, 01; MP PMT 2000, 01, 09; AIIMS 2001, 02; Kerala PMT 2002, 08; CPMT 2005; Odisha JEE 2011; CBSE PMT (Pre.) 2012] Or Photorespiratory reactions are operated in (a) Chloroplast, mitochondria (b) Mitochondria, peroxysome (c) Chloroplasts, peroxysome, mitochondria (d) Chloroplasts, cytoplasm, mitochondria Which one is false about kranz anatomy 59. **ICPMT 20051** (a) Bundle sheath have large chloroplast and less developed grana (b) Mesophyll cells have large chloroplast and more (c) It is found in Atriplex, sugarcane, maize (d) Plant having it have better photosynthesizing power than C3 plants The entire reactions of C4 pathway takes place in 60. [WB JEE 2016] (a) Mesophyll and bundle sheath (b) Vascular bundle and palisade tissue (c) Mitochondria and peroxisome (d) Bundle sheath and endoplasmic reticulum Bacterial photosynthesis 1. Bacteria that uses chemical energy to fix CO2 are known as [Odisha JEE 2010] (a) Chemoautotroph (b) Photoautotroph

(c) Heterotroph

All life on earth derive its energy directly or indirectly from 2. [CBSE PMT 1994] (a) Mushroom and mould (b) Chemosynthetic bacteria (c) Symbiotic bacteria (d) Pathogenic bacteria Which one of the following categories of organisms do not 3. evolve oxygen during photosynthesis [CPMT 1999, 2003; JIPMER 1999; AIIMS 2004; RPMT 2006] (a) Red algae (b) Photosynthetic bacteria (c) C₄ plants with Kranz anatomy (d) Blue green algae The site of photosynthesis in blue green algae is [MP PMT 2009] Or Photosynthetic bacteria have pigments in [CBSE PMT 1999; RPMT 1999; Bihar CECE 2006] (a) Chromatophores (b) Mitochondria (d) Root hair (c) Chloroplast In the bacterial photosynthesis, hydrogen donor is 5. (b) NH₂ (a) H₂ S (d) H2 SO4 (c) H₂O Which wavelength of light carry out photosynthesis in 6. (b) Blue (a) Ultraviolet light (d) Far red (c) Red Leptothrix is a (a) Nitrifying bacteria (b) Sulphur bacteria (d) Hydrogen bacteria (c) Iron bacteria Green bacteria contains (a) Chlorobium chlorophyll-660 (b) Chlorobium chlorophyll-650 (c) Both (a) and (b) (d) Chlorobium chlorophyll-700 Bacterial photosynthesis takes place in [RPMT 1995] 9. (a) Cytoplasm (b) Chromoplast (c) Chloroplast (d) Oxysome Chlorophyll a is absent in which of the following 10. [BVP 2004] photosynthetic organism (a) Cyanobacteria (b) Red algae (c) Brown algae (d) Bacteria Which of the following bacteria grow on isopropyl alcohol 11. and convert it into acetone (a) Fermentative bacteria (b) Chemosynthetic bacteria (c) Photosynthetic purple non-sulphur bacteria (d) Nitrifying bacteria

Bacterial photosynthesis involves

(d) PS-II only

(a) Both PS-I and PS-II

(c) PS-I only

[KCET 2004]

(b) Either PS-I or PS-II

12.

(d) None of these

Photosynthesis in Higher Plants 681 13. Which of the following photosynthetic bacteria have both 9. Which one of the following is not a limiting factor for PS-I and PS-II photosynthesis [KCET 1999] Or (a) Oxygen (b) Carbon dioxide Which was first photosynthetic organism [BVP 2004] (c) Chlorophyll (d) Light (a) Green sulphur bacteria (b) Purple sulphur bacteria If the rate of translocation of food is slow, what will be the 10. (c) Cyanobacteria (d) Purple non-sulphur bacteria effect on photosynthesis Factors affecting photosynthesis (a) It will increase (b) It will remain same Which of the following inhibits O_2 release in light phase 1. (c) Becomes double (d) It will decrease Which of the following wavelength of light is absorbed 11. maximum for photosynthesis (a) PMA (b) Zeatin (c) DCMU (d) None of these Chl. a absorb's max of [MP PMT 2005] Which factor is not limiting in normal conditions for (a) Red light (b) Blue light photosynthesis [MHCET 2003] (a) Air (c) Green light (b) CO2 (d) Yellow light (c) Water (d) Chlorophyll 12. In which of the following the rate of photosynthesis is 3. Blackman's law of limiting factor is applied to decreased and is known as red drop [MP PMT 1992] [NCERT; RPMT 1999; AIIMS 2001] (a) Blue light (a) Growth (b) Respiration (b) Green light (c) Transpiration (d) Photosynthesis (c) Red light more than 680 nm 4. The algae found in high temperature ponds are capable of (d) Red light less than 680 nm doing photosynthesis upto 13. Q₁₀ refers to (a) 30° C [RPMT 1997] (b) 75° C (c) 90° C (a) Quality quotient (d) 100° C (b) Temperature quotient 5. What is called Warburg's effect on photosynthesis (c) Respiratory quotient (d) Quantum constant [MP PMT 2003] 14. A plant is kept in 300ppm CO2 concentration, what will (a) Low rate of the process due to O2 supply happen to it (b) Low rate of the process due to CO2 supply (a) Plant will die soon (c) Both (a) and (b) (b) Plant will grow but will not die (c) Plant will show normal photosynthesis (d) None of the above (d) Respiration will be greatly decreased 6. When NaHCO3 is added in small quantity in an experiment 15. What will be the effect of intermittent light on photosynthesis showing photosynthesis, what will be the effect on it (a) It will increase (b) It will decrease (a) Rate will be lowered (b) Rate will be increased (c) Will not be effected (c) Rate will be normal (d) Process will stop (d) Process will stop What will be the effect when very high intensity of light is 7. The most effective wavelength of visible light in supplied to a photosynthesis system photosynthesis is in the region of [CBSE PMT 1999; RPMT 1999; CPMT 2000, 10; MP PMT 2000, 10,11; (a) Process will increase (b) Process will decrease Kerala CET 2003; AFMC 2003; DPMT 20041 (a) Violet (c) Process will stop due to solarization (b) Green (d) None of the above (c) Yellow (d) Red Which of the following conditions are favourable for cyclic 8. Compensation point is [CPMT 1998, 99; AFMC 2002] photophosphorylation [CPMT 1999] (a) Where there is neither photosynthesis nor respiration (a) Anaerobic condition (b) When rate of photosynthesis is equal to the rate of (b) Aerobic and optimum light respiration (c) Aerobic and low light intensity (d) Anaerobic and low light intensity (c) When entire food synthesized into photosynthesis

(upto -35° C) are

18.

remain utilized

requirements of plant

(d) When there is enough water just to meet the

(b) Blue-green algae

(a) Conifers (c) Xerophytes

(d) Tropical plants

Plants which can photosynthesize at as low temperature

- When a photosynthetic plant is transferred to an atmosphere of enriched O2, its rate of
 - (a) Photosynthesis would increase
 - (b) Photosynthesis would decrease
 - (c) Respiration would decrease
 - (d) Osmosis would increase
- 20. Under conditions of constant illumination, the compensation period for a whole aquarium would be of infinite length
 - (a) The biomass of animals equals the biomass of plants
 - (b) The respiratory exchanges of the animals are equal to the photosynthetic exchanges of the plants
 - (c) The oxygen intake of the animals equals of oxygen output of photosynthesis
 - (d) The carbon dioxide output of the animals and plants equals to the photosynthetic intake of the plants
- 21. In nature the photosynthesis should proceed upto the limit of
 - (a) Light
- (b) Temperature
- (c) CO₂
- (d) Moisture and wind
- 22. Which of the following would happen if the supply of O2 is decreased to an illuminated wheat plant
 - (a) Its photosynthesis would decrease
 - (b) Its respiration would increase
 - (c) Its photosynthesis would increase
 - (d) All the physiological process would stop
- With reference to factors affecting the rate of photosynthesis, which of the following statements is not correct [NEET 2017]
 - (a) Light saturation for CO2 fixation occurs at 10% of full sunlight
 - (b) Increasing atmospheric CO₂ concentration up to 0.05% can enhance CO2 fixation rate
 - C₃ plants respond to higher temperatures with enhanced photosynthesis while C4 plants have much lower temperature optimum
 - (d) Tomato is a greenhouse crop which can be grown in CO2 enriched atmosphere for higher yield

VCERT

Exemplar Questions

[NCERT]

[NCERT]

- 1. Which metal ion is a constituent of chlorophyll (a) Iron
 - (b) Copper
 - (c) Magnesium
- (d) Zinc
- Which pigment acts directly to convert light energy to chemical energy [NCERT]
 - (a) Chlorophyll a
- (b) Chlorophyll b
- (c) Xanthophyll
- (d) Carotenoid
- 3. Chemosynthetic bacteria obtain energy from
- (b) Infra red rays
- (c) Organic substance
- (d) Inorganic chemicals
- Energy required for ATP synthesis in PSII comes from
 - (a) Proton gradient
- (b) Electron gradient
- Reduction of glucose
- (d) Oxidation of glucose

- 5. During light reaction in photosynthesis the following are formed [NCERT]
 - (a) ATP and sugar
 - (b) Hydrogen, O2 and sugar
 - (c) ATP, hydrogen donor and O2
 - (d) ATP, hydrogen and O2 donor
- 6. Dark reaction in photosynthesis is called so because

[NCERT]

- (a) It can occur in dark also
- (b) It does not depend on light energy
- (c) It cannot occur during day light
- (d) It occurs more rapidly at night
- 7. When CO2 is added to PEP, the first stable product synthesized is [NCERT]
 - (a) Pyruvate
 - (b) Glyceraldehyde-3-phosphate
 - (c) Phosphoglycerate
 - (d) Oxaloacetate
- Splitting of water is associated with

[NCERT]

- (a) Photosystem I
- (b) Lumen of thylakoid
- Both Photosystem I and II
- (d) Inner surface of thylakoid membrane
- The correct sequence of flow of electrons in the light reaction 9. INCERTI
 - (a) PSII, plastoquinone, cytochromes, PSI, ferredoxin
 - PSI, plastoquinone, cytochromes, PSII, ferredoxin
 - PSI, ferredoxin, PSII
 - (d) PSI, plastoquinone, cytochromes, PSII, ferredoxin
- The enzyme that is not found in a C_3 plant is [NCERT]
 - (a) RuBP Carboxylase
 - (b) PEP Carboxylase
 - (c) NADP reductase (d) ATP synthase
- The reaction that is responsible for the primary fixation of CO2 is catalysed by [NCERT]
 - (a) RuBP carboxylase
 - (b) PEP carboxylase
 - (c) RuBP carboxylase and PEP carboxylase
 - (d) PGA synthase

Critical Thinking

Objective Questions

- Which is the evidence to show that O2 is released in photosynthesis comes from water
 - (a) Isotopic O₂ supplied as H₂O appears in the O₂ released in photosynthesis
 - Isolated chloroplast in water releases O2 if supplied potassium ferrocyanide or some other reducing agent
 - (c) Photosynthetic bacteria use H2S and CO2 to make carbohydrates
 - (d) All the above

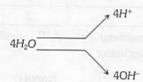

- 2. What effect would occur on photosynthesis, if the amount of oxygen in the atmosphere decreases
 - (a) Increase in C3 cycle and decrease in C4 cycle
 - (b) Increase in C₄ cycle and decrease in C₃ cycle
 - (c) Increase in C₃ cycle and no change in C₄ cycle
 - (d) Increase in C₄ cycle and no change in C₃ cycle
- 3. Read the following four statements (A-D)
 - (A) Both, photophosphorylation and oxidative phoshorylation involve uphill transport of protons across the membrane
 - (B) In dicot stems, a new cambium originates from cells of pericycle at the time of secondary growth
 - (C) Stamens in flowers of Gloriosa and Petunia are polyandrous
 - (D) Symbiotic nitrogen-fixers occur in free-living state also in soil

How many of the above statements are right

[CBSE PMT (Mains) 2012]

- (a) Two
- (b) Three
- (c) Four
- One
- Which of the following may show photosynthesis in moonlight
 - (a) Some thermal algae
- (b) Some marine algae
- (c) Some fresh water algae (d) None of the above

5.

In this process which of the following play important role

[GUJCET 2015; MHCET 2015]

- (a) Chlorophyll
- (b) Light energy
- (c) Ca++, Mn++, CI-
- (d) All of the above
- 6. Chloroplast contains maximum quantity of

[BCECE 2005, 06]

- (a) Pyruvic carboxylase
- (b) Hexokinase
- (c) RuBP carboxylase
- (d) None of the above
- 7. What is common between photosynthesis and respiration

[MP PMT 1993, 96, 2003, 06;

BHU 1995; AFMC 1995; Haryana PMT 2005; MH CET 2005; DPMT 2006; KCET 20061

- (a) Cytochrome
- (b) Light
- (c) H₂O
- (d) Temperature
- 8. Photosynthesis is INCERT:

MH CET 2002; Odisha JEE 2012; MP PMT 2013]

- (a) Oxidative, exergonic, catabolic
- (b) Reductive, endergonic, anabolic
- (c) Reductive, exergonic, anabolic
- (d) Reductive, endergonic, catabolic

- 9. Which of the following can photosynthesize at low temperature (-20°C) [BVP 2000]
 - (a) Bacteria
- (b) Lichen
- (c) Yeast
- (d) Batrachospermum
- The electron transport chain of photosynthetic process is 10.

[JIPMER 2002]

- (a) In the stroma of the chloroplast
- (b) Bound to the thylakoid membranes
- (c) Present in the outer membrane of the chloroplast
- (d) Present in mitochondria
- What percentage of usable radiant energy entering a 11. reaction site of photosynthesis is converted to potential energy [BHU 2002]
 - (a) 10%
- (b) 20%
- (c) 35%
- (d) 42%
- 12. Chlorophyll 'a' is found in
- [CBSE PMT 1992]
- (a) All oxygen releasing photosynthetic forms
- (b) All plants except fungi
- (c) All higher plants that photosynthesize
- (d) All photosynthetic prokaryotes and eukaryotes
- The empirical formula for chlorophyll 'a' is 13.

[KCET 1994, 2000; AFMC 1994;

Wardha 2005; J & K CET 2008; WB JEE 2016]

- (a) $C_{35}H_{72}O_5N_4Mg$
- (b) C₅₅H₇₀O₆N₄Mg
- (c) $C_{55}H_{72}O_5N_4Mg$
- (d) C₅₄H₇₀O₆N₄Mg
- 14. Which of the following is wrongly matched

[Kerala PMT 2010]

- (a) Sorghum
- Kranz Anatomy
- (b) PEP carboxylase
- Mesophyll cells Law of limiting factors
- (c) Blackman (d) Photorespiration
- C₃ plants
- P700
- 15. Chlorophyll 'a' molecule at its carbon atom 3 of the pyrrole ring II has one of the following
 - [CBSE PMT 1996, 97]
 - (a) Aldehyde group
- (b) Methyl group
- (c) Carboxylic group
- (d) Magnesium
- 16. Bacteriochlorophyll differs from chlorophyll 'a' in having
 - (a) One pyrrol ring with one hydrogen
 - (b) One pyrrol ring with two hydrogen
 - (c) One pyrrol ring with three hydrogen
 - (d) One pyrrol ring with four hydrogen
- 17. In photosynthesis, photolysis of water is used in

[CPMT 1998]

- (a) Reduction of NADP
- (b) Oxidation of NADP
- (c) Oxidation of FAD
- (d) None of these

- 18. C4 plants are found among
 - (a) Gramineae only
- (b) Monocots only
- (c) Dicots only
- (d) Monocots as well as dicots
- 19. Energy transfer in photosynthesis occurs as

[BHU 2003]

- (a) Phycoerythrin → Phycocyanin → Carotenoid
 - → Chlorophyll a
- (b) Chlorophyll $b \rightarrow$ Carotenoid \rightarrow Phycoerythrin
 - → Chlorophyll a
- (c) $Phycocyanin \rightarrow Phycoerythrin \rightarrow Carotenoid$
 - → Chlorophyll a
- (d) Chlorophyll → Carotenoid → Phycocyanin
 - → Chlorophyll a
- 20. Photosynthesis consists of essentially two biological reaction systems, one followed by the other, the second of these systems does which of the following
 - (a) Fixes CO₂
 - (b) Traps light energy
 - (c) Synthesizes starch
 - (d) Works only in the presence of light
- During dark reaction for fixation of carbon, the three carbon atoms of each molecule of 3-phosphoglyceric acid (PGA) are derived from [BHU 1994]
 - (a) RuBP only
- (b) CO2 only
- (c) $RuBP + CO_2$
- (d) $RuBP + CO_2 + PEP$
- 22. Calvin's cycle is found in
- [RPMT 1997]

400

Plasmo-desmata

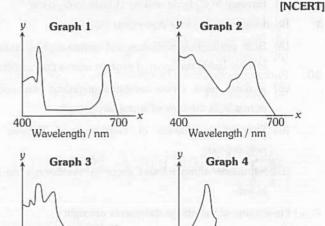

- (a) Only C₃ plants
- (b) Only photophillous plants
- (c) All C₄ plants
- (d) All photosynthetic plants
- 23. The first intermediate formed during photosynthesis is

[CPMT 2000]

- (a) Fructose 1, 6-diphosphate
- (b) Ribulose 1, 5-biphosphate
- (c) Xylulose-5-phosphate
- (d) Phosphoglyceraldehyde
- First transitory chemical formed by reaction between CO₂ and RuBP is [J & K CET 2002]
 - (a) PGAL/GAP
 - (b) 2-Carboxy, 3- keto, 1-5-biphospho ribotol
 - (c) PGA
 - (d) Dihydroxy acetone phosphate
- **25.** As compared to a C_3 plant, how many additional molecules of ATP are needed for net production of one molecule hexose sugar by C_4 plants [CBSE PMT 2005]
 - (a) Two
- (b) Six
- (c) Zero
- (d) Twelve

26. Three of the graphs below show the absorption spectra of photosynthetic pigments. One graph shows the action spectrum of photosynthesis for a plant containing the pigments.

All the x axis show wavelength. Three of the y axis show light absorption. One y axis shows the rate of photosynthesis

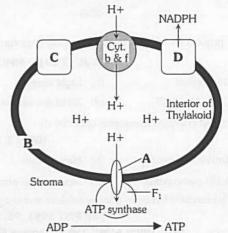

H	Chlorophyll a	Absorption Chlorophyll b	Spectra Carotenoids	Action spectrum
(a)	3	2	4	1
(b)	2	4	3	1
(c)	2	1	3	4
(d)	1	4	3	2

700

Wavelength / nm

700

27. Observe the pathway of ATP synthesis through chemiosmosis given below

Select the right answer in which correct words for all the four blanks A, B, C and D are indicated [NCERT]

- (a) A F₀, B Thylakoid membrane, C Photosystem (II),D Photosystem (I)
- (b) A F₁, B Thylakoid membrane, C Photosystem (II),
 D Photosystem (I)
- (c) A F₀, B Thylakoid membrane, C Photosystem (I), D
 Photosystem (II)
- (d) A F₁, B Thylakoid membrane, C Photosystem (I), D- Photosystem (II)

UNIVERSAL BOOK DEPOT 1960

- 28. Chromatophores take part in
 (a) Growth
 (b) Movement
 (c) Respiration
 (d) Photosynthesis

 29. In a chloroplast the highest number of protons are found in
 [NEET (Phase-I) 2016]
 - (a) Stroma
 - (b) Lumen of thylakoids
 - (c) Inter membrane space
 - (d) Antennae complex
- 30. Photosynthesis cannot be operated in [WB JEE 2016]
 - (a) Red light
- (b) Yellow light
- (c) Green light
- (d) Blue light

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- Assertion : C₄ pathway of CO₂ fixation is found in some tropical plants.
 - Reason : In this pathway CO_2 is fixed by 3C compound. [AIIMS 1998]
- Assertion : Six molecules of CO₂ and twelve molecules of NADPH⁺+H⁺ and 18 ATP are used to form one hexose molecule.
 - Reason : Light reaction results in formation of ATP
- and NADPH₂ [AIIMS 2002]
- Assertion : Rhoeo leaves contain anthocyanin pigments in epidermal cells.
 - Reason : Anthocyanins are accessory photosynthetic pigments. [AIIMS 2003]
- 4. Assertion : There is a decrease in photosynthesis, if the photosynthetic cells are illuminated by light of P₆₈₀ nm or more wavelength.
 - Reason : In red drop phenomenon the rate of photosynthesis decreases.
- **5.** Assertion : The concentration of O_2 in the atmosphere is inhibitory to photosynthesis.
 - Reason : Oxygen inhibitory effect is due to Warburg effect.

- **6.** Assertion : C_4 photosynthetic pathway is more efficient than the C_3 pathway.
 - Reason : Photorespiration is suppressed in C_4 plants.
- Assertion : CAM plants lack structural compartmentation of leaf, as found in C₄ plants.
 - Reason : Stomata of CAM plants are open during
- **8.** Assertion : Plants utilizing first RuBP in CO_2 fixations are called C_3 plants.
 - Reason : Plants utilizing first PEP in CO_2 fixations are called C_4 plants.
- **9.** Assertion : Cyclic pathway of photosynthesis first appeared in some eubacterial species.
 - Reason : Oxygen started accumulating in the atmosphere after the non-cyclic pathway of photosynthesis evolved. [AIIMS 2004, 07]
- 10. Assertion : The stromal thylakoids are rich in both PS I and PS II.
 - Reason : The granal membranes are rich in ATP synthetase.
- **11.** Assertion : Cyclic photophosphorylation synthesizes ATP
 - Reason : ATP synthesize in cyclic photophosphorylation is not associated with NADPH formation.
- 12. Assertion : Oxidative phosphorylation requires oxygen.

 Reason : Oxidative photophosphorylation occurs in
- mitochondria.

 13. Assertion : Each molecule of ribulose-1, 5-biphosphate fixes one molecule of CO₂.
 - Reason : Three molecules of NADPH and two ATP are required for fixation of one molecule of CO₂.
- **14.** Assertion : CO_2 is transported from mesophyll cells to bundle sheath of chloroplasts in C_4 plants.
 - Reason : RuBP is called final acceptor of CO₂ in C₄
- **15.** Assertion : One molecule of CO_2 is fixed to give 686 kcal in photosynthesis.
 - Reason : To form a hexose, six molecules of CO₂ are fixed.
- **16.** Assertion : In the formation of one glucose, 686,000 calories energy are produced.
 - Reason: The energy is provided by a total of 12 NADPH and 18 ATP.
- Assertion : Sciophytes require higher light intensity than heliophytes.
- Reason : Sciophytes grow below the canopy of trees.
- **18.** Assertion : Plants utilize 5-10% of the absorbed water in photosynthesis.
 - Reason : Reduced leaf hydration decrease the photosynthesis.

Answers and Solutions

History of photosynthesis

- (a) Blackman propounded the law of limiting factors. He also proposed the occurrence of a dark phase in photosynthesis.
- 3. (c) The discovery of Emerson effect. One group of pigments absorbs light of both shorter and longer wavelengths (more than 680nm) and another group of pigment absorbs light of only shorter wavelengths (less than 680nm). These two groups of pigments are known as pigment systems or photosystems.

- 4. (a) Malvin Calvin (1954) traced the pathway of carbon in photosynthesis and gave the C₃ cycle, (now known after him as calvin cycle). He was awarded Nobel prize for this work in 1960.
- (a) Malvin calvin and his coworkers in 1954 by using the methods of radio active tracer technique, chromatography and Autoradiography.
- 6. (b) Arnon etal. (1954) first of all demonstrated that isolated chloroplasts can produce ATP from ADP+ip and they called this ATP production as photophosphorylation.
- (d) Pelletier and Caventou (1818) discovered chlorophyll. It could be separated from leaf by boiling in alcohol.
- 8. (d) Robert Mayer (1845) proposed that light has radiant energy and this radiant energy is converted into chemical energy by plants, which serves to maintain life of the plants and also animals.
- (d) Thylakoids (Menke, 1961) or baggy trousers are structural elements of chloroplast.
- (b) According to Jan Ingen-Housz (1779), both green parts and sunlight are required for air purification and plant nourishment.
- 11. (d) Bousingault (1860) reported that amount of O₂ evolved in photosynthesis is equal to amount of CO₂ absorbed and both these processes occur simultaneously as soon as light is given.
- 12. (c) Helmont concluded that "all food of the plant is derived from rain water and not from soil and all parts of the plant develop from water".
- (c) Hatch and Slack (1965) discovered the C₄ pathway for CO₂ fixation in certain tropical grasses.
- 15. (a) In 1930 C.B. Van Niel proved that, sulphur bacteria use H_2S (in place of water) and CO_2 to synthesize carbohydrates as follows:

$$6CO_2 + 12H_2S \longrightarrow C_6H_{12}O_6 + 6H_2O + 12S$$

This led Van Niel to the pastulation that in green plants, water (H_2O) is utilized in place of H_2S and O_2 is evolved in place of sulphur (S). He indicated that water is electron donar in photosynthesis.

$$6CO_2 + 12H_2O \longrightarrow C_6H_{12}O_6 + 6H_2O + 6O_2$$

Experiments

- (d) Both blue and red wavelength are affective because the amount of oxygen released was found to be maximum in blue and red absorption bands of the chlorophyll.
- 3. (a) During photosynthesis O₂ evolved by the hydrolysis of water. If H₂O¹⁸ is used in 'A' plant then it become true that O¹⁸ type oxygen evolved from 'A' plant during photosynthesis.

UNIVERSAL BOOK DEPOT 1960

688 Photosynthesis in Higher Plants

- **4.** (a) C^{14} isotope used for knowing carbon path and O^{18} used for verified that source of O_2 in photosynthesis is H_2O , not CO_2 .
- (b) Ruben and Kamen used C¹⁴ radioactive isotopes in chlorella for knowing path of carbon in photosynthesis.
- 9. (b) Calvin traced the path in photosynthesis associated with dark reaction. Radioactive isotope of carbon (C¹⁴) is used, it is observed that (C¹⁴O₂) reduction of CO₂ is definitely in dark reaction.
- 10. (a) Calvin used isotopes C¹⁴ in chlorella for knowing carbon path in photosynthesis. Chlorella is a unicellular alga is using by Ruben Kamen and warburg. Because algae carry out 90% of photosynthesis.
- 11. (a) Photolysis occur in presence of light quanta and requires Mn^{++} and Cl^- ions as catalyst for water oxidising.

$$4H_2O \xrightarrow{Mn^{++}Cl^-} 4(OH)^- + 4H^+$$

Then H radicle forms water and O_2 as a by product $4OH \longrightarrow 2H_2O + O_2 \uparrow$

12. (b) Emerson and Arnold proved the existence of light and dark reaction by flashing of light experiment in photosynthesis.

Photosynthetic apparatus

 (a) In Etiolation, chlorophyll (green) converts in protochlorophyll (yellow) in dark, etiolin hormone is formed due to which plants become elongated.

Chlorophyll
$$\xrightarrow{\text{Dark}}$$
 Protochlorophyll + 2H $\xrightarrow{\text{(green)}}$ Light $\xrightarrow{\text{(yellow)}}$

- 2. (b) Photosynthesis by plants is most vital process for the existence of life on earth because photosynthesis helps to maintain the equilibrium position of O₂ and CO₂ in the atmosphere. It purifies the air and synthesize food for all living beings.
- 4. (b) $6CO_2 + 12H_2O \xrightarrow{\text{Sunlight} \atop \text{Chlorophyll}} C_6H_{12}O_6 + 6O_2 + 6H_2O$.
- 5. (b) When photon of light energy falls on chlorophyll molecule, one of the electrons pair from ground or singlet state passes into higher energy level called excited singlet state.
- 7. (b) The main function of chloroplast is photosynthesis, in which radiant energy of sun is converted into chemical form of energy (ATP), which is utilized by all living organisms to perform their life activities.
- (a) The addition of phosphate group to ADP and AMP called phosphorylation.

$$ADP + iP \longrightarrow ATP$$

By this process ATP is formed which is used in dark reaction.

- 9. (b) Photosynthesis reaction shows that "formation of carbohydrates from CO₂ and H₂O by illuminated green cells of plants, O₂ and H₂O are the bye products.
- **15.** (c) 90% of total photosynthesis is carried out by aquatic plants, chiefly algae (80% in oceans and 10% in fresh water). 10% of total photosynthesis is performed by land plants.
- 17. (b) ATP is formed during photophosphorylation after this reaction NADPH₂ and ATP move in dark reaction it is known as assimilatory power.
- 19. (b) $CO_2 + 2H_2O \xrightarrow{\text{Light energy}} (CH_2O)_n + H_2O + O_2 \uparrow$
- 22. (b) Rubisco constitutes 16% of chloroplast protein. It is the most abundant protein on this planet.
- 23. (d) Only 1-4% light is utilized in photosynthesis. In general rate of photosynthesis is more in intense light than diffused light.
- **24.** (d) Photosynthesis is an oxidation reduction process where H_2O is oxidized by photolysis into O_2 and CO_2 is reduced into carbohydrates.
- **26.** (a) Arnon (1956) used the term 'Assimilatory powers' for ATP and NADPH₂. (NADPH₂ alone is called reducing power).
- **29.** (a) Sugarcane is C_4 plant. The chloroplasts in C_4 leaves are dimorphic (Two morphologically distinct types). The chloroplasts of bundle sheath cells contain starch grains but lack grana. The mesophyll cells on the other hand, contain normal type of chloroplasts.
- **32.** (b) Because CO_2 is utilized in photosynthesis process by plants.
- **34.** (c) Burning of sugar, respiration in plants and heating of limestone is responsible for the liberation of CO_2 but in photosynthesis green plants take in CO_2 and release O_2 thus purifying the air.
- **35.** (b) Park and Biggins (1964) gave the term quantasome for photosynthetic units is equivalent to 230 chlorophyll molecules.
- **36.** (b) ATP (adenosine triphosphate) is called energy currency of cells. ATP is energy rich compound where energy is present in terminal pyrophosphate bonds.
- 37. (d) Light, chlorophyll, CO₂ and water all are essential in photosynthesis. In photosynthesis process energy rich compounds like carbohydrates are synthesized from simple inorganic compounds like carbon dioxide and water in the presence of chlorophyll and sunlight with liberation of O₂.

Light reaction/Pigments

- (c) The splitting of water during photosynthesis is called photolysis. Mn and Cl plays important role in photosynthesis specially light reaction of photosynthesis in splitting of water.
- (b) Chlorophyll-a is widely distributed in green plant and it is also called primary photosynthetic pigment and universal photosynthetic pigment.

- (a) The chloroplast pigment are fat soluble and are located in the lipid part of the thylakoid membranes.
- (d) Xanthophylls are yellow coloured carotenoid also called Xanthols or carotenols.
- 12. (c) Wavelength occur in red part of the spectrum is 650-760 nm.
- 33. (b) Non cyclic photophosphorylation involved both PS-I and PS-II. Flow of electrons is unidirectional. Here electrons are not cycled back and are used in the reduction of NADP to NADPH₂.
- 37. (c) Chl.-a 700 or P₇₀₀ is the reaction centre of PS-I.
- 38. (c) The colours of leaves is modified in certain plants due to the presence of purple pigment called anthocyanins. Anthocyanins are soluble in water, hence they occur in solution in the water of the cells.
- (a) Chlorophyll a is widely distributed in green algae and higher plants.
- 49. (c) During light reaction energy from sunlight is absorbed and converted into chemical energy which is stored in ATP and NADPH + H⁺.
- 50. (b) Core metal of chlorophyll is Mg. When central Mg is replaced by Fe, the chlorophyll becomes a green pigment called "cytochrome" which is used in photosynthesis.
- 52. (c) Phosphate is coupled with ADP to produce ATP using light energy during photosynthesis.
- 53. (a) Cytochromes are systems of electron-transferring proteins, with iron-porphyrin or copper-porphyrin as prosthetic groups.
- 55. (c) Photolysis means splitting of water molecules to release oxygen. This occurs in photosynthesis, i.e., Photosystem-II.
- (a) Chlorophyll is soluble in organic solvents like alcohol, acetone etc.
- 57. (a) Green plants and algae use two types of photosystems, PS-I with chl. P₇₀₀ in its reaction centre and PS-II with P₆₈₀ in its reaction centre. The two photosystems are linked by a chain of electron carriers. Light excites P₆₈₀ of PS-II to activated P₆₈₀.
- 58. (a) This non-cyclic photophosphorylation is also known as Z-Scheme (because of shape of path of electron – flow) and this was given by Hill and Bendall (1960).
- **61.** (a) The reaction centers of PS–I and PS–II can be denoted as P_{700^+} and P_{680^+} respectively. Positively charged reaction centers act as attractants for electrons.
- 63. (c) The important pigments of this system are chlorophyll a 670, chlorophyll a 683, chlorophyll a 695, P₇₀₀. Some physiologist also include carotenes and chlorophyll b in pigment system I. P₇₀₀ act as the reaction centre.

- 64. (c) Light energy brings about changes in Mn (Mn²⁺, Mn³⁺, Mn⁴⁺) which helps in removing electrons from OH⁻ component of water forming oxygen.
- 65. (a) Robert Hill (1939) first of all showed that if chloroplasts extracted from leaves of stellaria media and Lamium album are suspended in a test tube containing suitable electron acceptor e.g., potassium ferrooxalate and potassium ferricyanide, O₂ is released due to photochemical splitting of water.
- 69. (b) During light reaction not only reduced NADP is formed and O₂ is evolved but ATP is also formed. This formation of high energy phosphates (ATP) is dependent on light hence called photophosphorylation.
- 71. (a) Non cyclic photophosphorylation involves both PS-I and PS-II. The process begins with the absorption of light energy by PS-II. As light energy is absorbed, 4e⁻ become excited from chlorophyll -a at the reaction centre. The 4e⁻ released by these molecules are accepted by an electron acceptor substance. The other effect of this event is that photolysis of water is induced. The chlorophyll-a molecules in PS-II act as strong oxidising agent. As described earlier, 4 molecules of H₂O are thus decomposed through light-induced-energy. The 4H⁺ ions become associated with 2 NADP. The 4 OH⁻ ions are associated with the release of oxygen. The four electrons (4e⁻) released from 4 OH⁻ are received by chlorophyll-a molecules at reaction-centre of PS-II.
- 72. (b) The photosystem-II (Reaction centre of P-680) extracts an e⁻ from water returning to its unexcited state. The removal of four e⁻ from two molecules of water requires 4 quanta of light to fall on PS-II and leads to the production of 4H⁺ ions and one molecule of O₂.
- 79. (c) The absorption spectrum of chlorophyll a and chlorophyll b indicate that these pigments mainly absorb blue and red lights. Action spectrum shows that maximum photosynthesis takes place in blue and red regions of spectrum.
- 80. (b) The figure denotes non-cyclic photophosphorylations that involves both PS-I (reaction centre-700) and PS-II (reaction centre-680). The electrons released from PS II is not cycled back but is transported to PS-I through a series of chemical compounds. Before reaching PS-I, the electrons pass through plastocyanin.

Dark reaction

 (c) Dark reaction was first of all established by Blackman that's why it is called Blackman's reaction.

- (d) Dark reaction takes place in bundle sheath (because RuBISCO present in stroma of chloroplast of bundle sheath).
- 12. (c) A- Fixation of CO₂ by PEPCO
 B- Decarboxylation
 C- Regeneration
- 13. (a) Ribulose 1, 5-diphosphate carboxylase enzyme is first enzyme of Calvin cycle convert Ribulose-1, 5 diphosphate into 3-phosphoglyceric acid.
- (b) During photosynthesis PGA is reduced by NADP. 2H into phosphoglyceraldehyde.
- 16. (a) Calvin cycle occurs in the stroma of chloroplasts where the products of light reaction (assimilatory power NADP.2H + ATP) are used to form CO₂ to carbohydrate and it has enzymes essential for fixation of CO₂ and synthesis of sugar.
- 17. (b) The new name of dark reaction is carbon assimilation, in which CO_2 gas reacting with H_2O (liquid) synthesizes solid glucose.
- 18. (a) In C₃ cycle, in presence of rubisco (RuBP carboxylase) CO₂ combines with ribulose 1, 5-bisphosphate (acceptor molecule) to form 3-phosphoglyceric acid or 3-PGA which is the first stable product of carbon reduction cycle.
- 23. (b) As Calvin cycle takes only one carbon (as CO₂) at a time. So it takes six turns of the cycle to produce a net gain of one hexose or glucose.
- 25. (c) Reductive carboxylation start with a 5 carbon sugar ribulose 5 phosphate. 6 mol of this sugar react with 6 mol of ATP (produced in light reaction) to form 6 mol of RuBP and 6 mol ADP
 Ribulose 5 phosphate
 Phosphopentokinase

Ribulose 1, 5-biphosphate + 6ADP

- 29. (c) Ribulose 1, 5-diphosphate (also known as ribulose biphosphate) a phosphorylated 5 carbon sugar (pentose sugar) it is first attached with CO_2 in photosynthesis.
- (b) Calvin cycle is divided into three distinct phase but carboxylation occur only one time.

C₄/CAM/Photorespiration

 (d) This pathway was first reported in members of family gramineae (grasses) like sugarcane, maize etc. More than 300 species belong to dicots and the rest belong to monocots. There are no known C₄ gymnosperms, bryophytes or algae.

- 9. (a) Photorespiration is a process of respiration which takes place in the presence of light and in chloroplasts only. In this process, first of all RuBP is oxygenated in presence of O2. Then, 1 molecule of a 2-C phosphoglycolate and 1 mol. of a 3C PGA are formed from it. The PGA molecule is used in the Calvin cycle. Phosphoglycolate is dephosphorylated and glycolate is formed. Glycolate diffuses out of chloroplast and enters the organelle called peroxisome. Here it is oxidized and becomes glyoxylate. Glyoxylate is used in synthesis of glycine.
- 11. (d) Photorespiration is quite different from respiration as no ATP or NADH are produced, the energy released being lost as heat. Moreover, the process is harmful to plants because as much as half the photosynthetically fixed CO₂ (in the form of RuBP) may be lost into the atmosphere through this process.
- 18. (a) One of the basic features of C₄ plants is that CO₂ is trapped by a CO₂ acceptor, phosphoenol pyruvic acid present in the (PEP) chloroplasts of mesophyll cells of these leaves, leading to the formation of a 4-C compound oxaloactic acid.
- 19. (b) In Hatch-Slack pathway, first product of CO₂ fixation is a 4 carbon compound, oxaloacetic acid hence they are called C₄ plants. This acid is converted to another 4-C acid, the malic acid.
- 20. (c) Basic feature of C₄ plants is the occurrence of "Kranz" (German term meaning halo or wreath) type of leaf anatomy. The vascular bundles, in C₄ leaves are surrounded by a layer of bundle sheath cells that contain large number of chloroplasts. The chloroplast in C₄ leaves are dimorphic (Two morphologically distinct type).
- **23.** (d) Photorespiration is absent in C_4 plants due to presence of kranz anatomy.
- 27. (b) These are succulent plants with water storing cells.
- 28. (b) In C₄ plants agranal chloroplast occur in bundle sheath.
- 29. (a) In C₄ plants initial CO₂ fixation occurs in Mesophyll cells. As a result malic acid is formed. This malic acid is transfermed in Bundle sheath chloroplast where it is decarboxylated.
- **30.** (c) C_3 and C_4 cycle both occurs in panicum milioides hence it stand intermediate between C_3 and C_4 plants.
- **32.** (b) C_4 plants utilise solar energy most efficiently. Because photosynthesis rate is very high in C_4 plants e.g., Sugarcane, maize etc.
- 33. (a) In crassulacean acid metabolism (CAM) plants large amount of acid like malic acid etc. are synthesized at night. The stomata remain closed the day time but remain open at night. CAM plants are succulent drought evading plants.

- 38. (b) In CAM plants there is no kranz anatomy, but there occurs dark acidification, i.e., during night malic acid is formed. This malic acid breaks up into CO₂ and pyruvic acid in day time and CO₂ released is utilized in C-3 cycle.
- 40. (b) In 1965 kortschak, Hart and Burr working with C¹⁴O₂ on sugarcane leaves found C₄ dicarboxylic acid, malate and aspartate to be the major labelled products in very short periods of photosynthesis. This observation was confirmed by M.D. Hatch and C.R., Slack in 1967. The Hatch-slack pathway, as this alternative CO₂ fixation is called, has been found to occur in tropical and sub-tropical grasses and some dicotyledons.
- 46. (a) In C₄ plants poor supply of CO₂. Because there is a internal supply of CO₂. So these plants can survive in poor CO₂ conditions.
- (c) Phosphoenol pyruvic acid carboxylase fixed CO₂ in sugarcane. Due to this enzyme PEP + CO₂ converted into oxaloacetic acid.
- 48. (d) Photorespiration is absent in C_4 plants.
- **50.** (a) PCO or photorespiration is also called C_2 cycle as there is synthesis of 2-carbon compound.
- 51. (c) Three conditions are required for photorespiration (1)
 High O₂ concentration (2) Low concentration of CO₂
 (3) High light intensity. During photorespiration oxygenation takes place firstly.
- 52. (d) Glyoxylate is used to form glycine, glycine enters in mitochondria where two glycine molecules give rise to one molecule of serine and one CO₂.
- **53.** (b) Two times carboxylation occur in C_4 cycle, first carboxylation is done by phosphoenole pyruvate and second in bundle sheath cell by Ribulose 1, 5 biphosphate.
- 54. (b) Bundle sheath chloroplast larger in size, lack grana (Agranal chloroplast) and contain starch grains. Mesophyll chloroplast small in size, contain grana and lack starch grains.
- (b) The process of photorespiration involves the involvement of chloroplast, peroxysome and mitochondria.

Bacterial photosynthesis

(b) Chemosynthetic bacteria are able to manufacture all their organic food from inorganic raw material in the absence of light.

$$6CO_2 + 24 \text{ [H]} \xrightarrow{\text{Enzymes/Energy}} C_6H_{12}O_6 + 6H_2O$$

3. (b) Like cyanobacteria, algae, autotrophic plants and photoautotrophic bacteria also use light energy for reducing CO₂ to organic compounds but water is never used as a source of electrons in bacteria. Hence, oxygen is never evolved during bacterial photosynthesis.

- (a) The bacterial pigments are however not contained in chloroplast but are present in structures called chromatophores.
- 5. (a) $CO_2 + 2H_2S \xrightarrow{\text{Sunlight}} (CH_2O) + 2S + H_2O + \text{Energy}$
- (d) Photosynthetic bacteria absorb (850-950nm) infra-red wavelength.
- 7. (c) Leptothrix, is a iron bacteria oxidise $Fe^{2+} \longrightarrow Fe^{3+} + \text{chemical energy}$.
- (c) Green bacteria contain green pigment bacterioviridin (chlorobium chlorophyll), which absorbs red light, showing maximum absorption in the region of 650-660.
- 10. (d) The photosynthetic bacteria use inorganic electron donor such as H₂S, H₂, sulphur compound etc. They contain bacterio-chlorophyll but chlorophyll a is absent.
- 11. (c) Purple non-sulphur bacteria contain purple pigment bacteriochlorophyll and carry on photosynthesis in presence of simple organic compounds like organic acids and alcohol e.g., Rhodospirillum rubrum.

$$2CH_3CHOHCH_3 + CO_2 \xrightarrow{\text{Sunlight}}$$

 $(CH_2O) + 2CH_3COCH_3 + H_2O$

13. (c) The oldest micro-fossils discovered so far are that of photosynthetic cyanobacteria that appeared 3.3 to 3.5 billion year ago.

Factors affecting photosynthesis

- (c) During light reaction of photosynthesis O₂ release as a result of photolysis of water. DCMU is a photosynthetic inhibitor which inactivates the PS-II and inhibit the Hill reaction.
- 3. (d) Law of limiting factor was proposed by Blackman in 1905. He stated that when a process is conditioned as to its rapidity by a number of separate factors, the rate of the process is limited by the pace of slowest factor.
- (b) The maximum temperature at which photosynthesis can occur is 55°C in some desert plants and 75°C for hot spring algae.
- 5. (a) German scientist Warburg (1920) reported in *chlorella* alga that high O_2 level inhibit rate of photosynthesis and this inhibition of photosynthesis by increased O_2 concentration is called Warburg's effect.
- (b) Rate will be increased due to the ejection of CO₂ from NaHCO₃.
- 7. (d) Blue and red regions of the light spectrum are the most effective in photosynthesis. Blue wavelengths of light carry more energy while red wavelengths have lesser energy. Therefore, the most efficient wavelengths of light effective in photosynthesis are those of light.
- 8. (b) Compensation point is existed in morning and evening time. At this time the rate of photosynthesis (intake of CO₂) and rate of respiration (outcome of CO₂) is equal. At this point no exchange of CO₂ is possible through stomata. The unit is lumen.

- 11. (b) Because blue colour comes first in spectrum light.
- (c) R. Emerson and C.M. Lewis (1943) observed that the quantum yield of photosynthesis decreased towards the far red end of the spectrum (680nm or longer).
- (c) Normal conc. of CO₂ in atmosphere is 0.03% (i.e., 300 ppm). By increases but after that it decreases.
- 15. (a) Because light reaction is much faster than dark reaction, so in continuous light there is accumulation of ATP and NADPH₂ and hence reduction in rate of photosynthesis but in discontinuous light, ATP and NADPH₂ formed in light are fully consumed during dark in reduction of CO₂ to carbohydrates.
- **22.** (c) If the amount of oxygen in the atmosphere decreases then photosynthesis will increase in C_3 cycle (wheat) and no change in C_4 cycle.

Critical Thinking Questions

- (b) Normally plants utilize sunlight but marine algae also use moon light, photosynthesis even occur in electric light.
- 6. (c) RuBP-oxygenase is a form of Rubisco, which constitutes 16% of chloroplast protein. It is the most abundant protein on this planet.
- (a) Cytochromes Hence proteins (iron containing proteins) serving as electron carriers in respiration photosynthesis and other oxidative reduction reactions.
- (b) Reduction of carbon, anabolised organic compound will give ATP during respiration. Photosynthesis is an anabolic and endothermic reaction. It is a mechanism of synthesis of food.
- (b) Lichen's can photosynthesize at very low temperature.
 i.e., -24°C.
- (a) Chlorophyll a occurs in all except photoautotrophic bacteria, i.e., all oxygenic photoautotrophs.
- 13. (c) Chlorophyll a is bluish-green with empirical formula of $C_{55}H_{72}O_5N_4Mg$.
- 16. (b) Purple sulphur bacteria and non-sulphur bacteria contain bacterio-chlorophyll, which is having 2H-atoms more than chl. a and it absorbs 850-950 nm (infra-red) wavelength of light.
- (d) C₄ plants mostly in monocot plants (Artiplex, sugarcane, maize, cyperus) and some dicots (Amaranthus).
- 21. (c) In carboxylation Ribulose 1, 5 biphosphate (RuBP) (= Ribulose diphosphate) acts as CO₂ acceptor and 6 mols of RuBP react with 6 mols of CO₂ and 6 mols of water giving rise to 12 mols of 3-phosphoglyceric acid.

- 23. (d) 3 molecules of CO₂ combine with 3 molecules of RuBP to produce 3 molecules of an unstable 6-C compound which immediately breaks down into molecules of 3-phosphoglyceric acid.
- 28. (d) Chromatophores contain pigments and they are found in blue green algae for photosynthesis.

Assertion and Reason

- (b) C₄ pathway found in tropical angiosperms and called as
 Hatch and Slack cycle. Here CO₂ is fixed by 3C
 compound (phosphoenol pyruvate, PEP).
- 2. (b) Six molecules of CO₂ enter Calvin cycle to produce one hexose molecule whereas 18 ATP, 12 NADPH + H⁺ molecules are used up. The light reaction of photosynthesis results in ATP and NADPH₂ formation.
- (c) Anthocyanin pigment, present in cell sap of vacuole. It is responsible for the colouration of flower parts. It is not a photosynthetic pigment.
- 4. (b) Although the efficiency of photosynthesis is uniform over most of the spectrum, it declines significantly in the red, i.e., at wavelength of 680 nm and above. This phenomenon is called red drop. However, it was shown by Emerson that if light at 680 nm is supplemented with light of a shorter wavelength (< 600 nm), the quantum efficiency of photosynthesis in the red can be restored to normal.</p>
- 5. (a) Small quantity of oxygen is essential for photosynthesis except in some anaerobic bacteria. The inhibition of photosynthesis at high O₂ levels may be due to (i) Oxygen takes part in oxidation of photosynthetic pigments, intermediates and enzymes in the presence of strong light (photo-oxidation), (ii) Oxygen is a strong quencher of excited state of chlorophyll, (iii) It converts RuBP carboxylase to RuBP-oxygen. At a very high oxygen content the rate of photosynthesis begins to decline in all plants. The phenomenon is called Warburg effect (reduction due to photorespiration).
- 6. (a) C₄ photosynthetic pathway is more efficient than C₃ pathway as C₄ plants can pick up CO₂ even when it is found in low concentration. PEP enzymes shows high affinity for CO₂. C₄ plants contain two types of chloroplast (Kranz anatomy): bundle sheath chloroplast and mesophyll chloroplast. Bundle sheath cells contain calvin cycle enzymes. Due to high concentration of CO₂ in bundle sheath cells, RuBP carboxylase works only for calvin cycle and not for photorespiration.

Photorespiration is a wasteful process as it works to undo the act of photosynthesis in C_4 plants. No energy rich compound is produced in this process. When temperature increase more and more photosynthetically fixed carbon is lost by photorespiration thus reducing the efficiency of C_3 plants.

- 7. (c) CAM plants do not exhibit the structural compartmentation (C₃ and C₄ cycles taking place in different cells) of conventional C₄ plants. CAM plants fix CO₂ at night because their stomata are open at night and closed during the day.
- 8. (b) Plants that utilize primarily RuBP to fix CO₂, which results in the formation of the three-carbon compound 3-PGA, are called C₃ plants. Hatch and Slack proposed a new pathway of CO₂ fixation via the carboxylation of PEP. Because the products are four-carbon compounds, plants exhibiting this pathway are referred to as C₄ plants.
- 9. (b) Cyclic pathway of photosynthesis is appeared first in some eubacterial species. It is supposed to be the first evidence of production of ATP in the presence of light. During non-cyclic photophosphorylation photolysis of water takes place. Under the influence of light energy and the catalytic action of chlorophyll, water a substance of low energy value, is split up into oxygen and hydrogen. Oxygen is used in the chloroplast. Non-cyclic photophosphorylation is the only natural process which adds molecular oxygen to the atmosphere.
- 10. (d) The grana stacks of membranes are enriched in PS II and LHC (Light harvesting centre), while there is little ATP synthetase. On the other hand, a fraction of stroma thylakoids is rich in PS I and ATPase and poor in PS II and LHC.
- 11. (b) In case of cyclic photophosphorylation, the electron, while passing between ferredoxin and plastoquinone and/or over the cytochrome complex the electron loses sufficient energy to form ATP from ADP and inorganic phosphate.
- 12. (b) The synthesis of ATP via electron flow through the ETS, with oxygen as the terminal electron acceptor, is known as oxidative phosphorylation and takes place in mitochondria. In contrast to the oxidative phosphorylation of mitochondria, O₂ is not used in photophosphorylation of chloroplasts and NADP⁺ is last electron acceptor.

- 13. (c) Each molecule of ribulose-1, 5-biphosphate fixes one molecule of carbon dioxide with the addition of water, thereby resulting in the formation of two molecules of 3-phosphoglyceric acid (3-PGA). The fixation and reduction of one molecule of CO₂ requires three molecules of ATP and two of NADPH, coming from the photochemical reactions.
- 14. (e) Malic acid or aspartic acid is translocated to bundle sheath cells through plasmodesmata. Inside the bundle sheath cells they are decarboxylated (and deaminated in case of aspartic acid) to form pyruvate and CO₂. CO₂ is again fixed inside the bundle sheath cells through Calvin cycle. RuBP of Calvin cycle is called secondary or final acceptor of CO₂ in C₄ plants.
- 15. (e) The overall equation of photosynthesis is $CO_2 + 2H_2O + n(h\nu) \rightarrow (CH_2O) + H_2O + O_2.$ The standard free-energy change for the synthesis of hexose from CO_2 and H_2O is $\Delta G^\circ = +686$ kcal. As six molecules of CO_2 is involved to form one molecule of hexose, the energy input per CO_2 molecule will be 114 kcal.
- 16. (a) The energy balance of photosynthesis is: $6CO_2 + 12H_2O \xrightarrow{light} C_6H_{12}O_6 + 6CO_2 + 6H_2O$ which represents a storage of 686,000 calories per mole. This energy is provided by a total of 12 NADPH and 18 ATP molecules, which represent 750,000 calories. The efficiency reached by the PCR cycle is thus as high as 90% (686/750 \times 100 = 90%).
- 17. (e) Plants are grouped into two groups depending upon their inability or ability to tolerate high light intensityshade plants (Sciophytes) and sun plants (Heliophytes). Sciophytes grow in poorly illuminated conditions as below the canopy of tall plants in seek of shade. Heliophytes grow in the open.
- 18. (e) Less than 1% of the total water absorbed is utilized in photosynthesis. The rest is lost in transpiration. Even a slight increase in transpiration reduces the leaf hydration that cuts down photosynthesis by causing stomatal closure and hence decreased CO₂ absorption, loss of leaf turgidity, reduced absorption of solar radiations and decrease enzymatic activity.

- 2. (b) Priestley demonstrated that green plants purify the foul air (i.e., phologiston) produced by burning of candle and convert it into pure air (i.e., Dephologiston).
- 5. (b) During formation of one glucose molecule in plant 3 ATP required for fixation of one CO₂ molecule. Thus in plants required 18 ATP and 12 NADPH₂.
- (b) There is two molecule of glycine used and interact to form one molecule each of serine CO₂ and NH₃.
 2Glycine+H₂O+NAD → Serine + CO₂+NH₃+NADP
- (d) Certain cell constituents are oxidized by oxygen into CO₂ as known as photo-oxidation.

- (b) Under the conditions of sufficient light and low CO₂ concentration, the rate of photosynthesis equals the rate of respiration (respiration and photorespiration together) in any plant. This concentration of atmospheric CO₂ absorbed from the atmosphere equals the amount of CO₂ at which the photosynthesis and respiration become balanced is called CO₂ compensation point. This compensation point is achieved when the amount of CO₂ absorbed from the atmosphere equals the amount of CO₂ released through plant respiration. However is necessary that available light does not become a limiting factor. At this point, effective photosynthesis becomes nil. The compensation point is higher in C₃ plants in relation to that in C₄ plants as rate of photorespiration is high in C₃ plants.
- 9. (a) Phytochrome is a proteinaceous pigment found in low concentrations in most plant organs. It exists in two forms P _{sub FR} (or P _{sub 660}) has an absorption peak at 660nm (red light) and the other P _{sub FR} (or P _{sub 730}) at 730nm (far-red).
- (b) Anthocyanin pigment is absent in chloroplast. It is present in cell sap of vacuole and not take any part in photosynthesis.
- (a) Chlorophyll a is found in all autotrophic plants except the photosynthetic bacteria.
- 13. (a) Here in C₄ plants, CO₂ acceptor molecule is PEP (Phosphoenol pyruvate) and in C₃ plant CO₂ molecule is RuBP (ribulose 1-5 biphosphate).
- (a) Rhodospirillum bacteria completed their photosynthesis by bacteriochlorophyll b. These are found in mud and stagnant water.
- (a) For desert plants like Opuntia required 50°C temperature for photosynthesis.
- 19. (d) CO₂ taken from the atmosphere is accepted by phosphoenolpyruvic acid (PEP) present in the chloroplast of mesophyll cells of these leaves, leading to the formation of a 4-C compound, oxaloacetic acid (OAA).

4.4

Cellular respiration is an enzyme controlled process of biological oxidation of food materials in a living cell, using molecular O_2 , producing CO_2 and H_2O , and releasing energy in small steps and storing it in biologically useful forms, generally ATP.

So respiration is catabolic, exothermic and oxidative process.

$$C_6H_{12}O_6+6O_2 \xrightarrow{\text{enzymes}} 6CO_2 +6H_2O+\text{energy}$$

glucose carbondioxide Water (ATP)

Use of energy: Cellular activities like active transport, muscle-contraction, bioluminescence, homothermy, locomotion, nerve impulse conduction, cell division, growth, development, seed germination require energy. Main source of energy for these endergonic activities in all living organisms including plants, comes from the oxidation of organic molecules.

The energy released by oxidation of organic molecules is actually transferred to the high energy terminal bonds of ATP, a form that can be readily utilized by the cell to do work. Once ATP is formed, its energy may be utilized at various places in the cell to drive energy- requiring reactions. In these processes, one of the three phosphate groups is removed from the ATP molecule. Thus the role of ATP as an intermediate energy transforming compound between energy releasing and energy consuming reactions.

Significance of respiration: Respiration plays a significant role in the life of plants. The important ones are given below:

 It releases energy, which is consumed in various metabolic processes necessary for life of plant.

- (2) Energy produced can be regulated according to requirement of all activities.
 - (3) It converts insoluble food into soluble form.
- (4) Intermediate products of cell respiration can be used in different metabolic pathways e.g.,

Acetyl- CoA (in the formation of fatty acid, cutin and isoprenoids); α - ketoglutaric acid (in the formation of glutamic acid); Oxaloacetic acid (in the formation of aspartic acid, pyrimidines and alkaloids); Succinyl- CoA (synthesis of pyrrole compounds of chlorophyll).

- (5) It liberates carbon dioxide, which is used in photosynthesis.
- (6) Krebs cycle is a common pathway of oxidative breakdown of carbohydrates, fatty acids and amino acids.
 - (7) It activates the different meristematic tissues of the plant.
- ${\it CO}_2$ intake in photosynthesis balanced with ${\it CO}_2$ release in respiration = Compensation point.

Comparison between respiration and combustion: According to Lavosier cell respiration resembles the combustion (e.g., burning of coal, wood, oil etc.) in the breakdown of complex organic compounds in the presence of oxygen and production of carbon dioxide and energy, but there are certain fundamental differences between the two processes:

Table: 4.4-1 Differences between cell respiration and combustion

S.No.	Characters	Cell respiration	Combustion
(i)	Nature of process	Biochemical and stepped process.	Physico-chemical and spontaneous process.
(ii)	Site of occurrence	Inside the cells.	Non-cellular.
(iii)	Control	Biological control.	Uncontrolled.
(iv)	Energy release	Energy released in steps.	Large amount of energy is released at a time.
(v)	Temperature	Remain within limits.	Rises very high.
(vi)	Light	No light is produced.	Light may be produced.
(vii)	Enzymes	Controlled by enzymes.	Not controlled by enzymes.
(viii)	Intermediates	A number of intermediates are produced.	No intermediate is produced.

Phases of respiration

There are three phases of respiration:

- External respiration: It is the exchange of respiratory gases (O₂ and CO₂) between an organism and its environment.
- (2) **Internal or Tissue respiration :** Exchange of respiratory gases between tissue and extra cellular environment .

Both the exchange of gases occur on the principle of diffusion.

(3) Cellular respiration: It is an enzymatically-controlled stepped chemical process in which glucose is oxidised inside the mitochondria to produce energy-rich ATP molecules with high-energy bonds.

So, respiration is a biochemical process.

Respiratory substrate or Fuel

In respiration many types of high energy compounds are oxidised. These are called respiratory substrate or respiratory fuel and may include carbohydrates, fats and protein.

- (1) Carbohydrate: Carbohydrates such as glucose, fructose (hexoses), sucrose (disaccharide) or starch, insulin, hemicellulose (polysaccharide) etc; are the main substrates. Glucose are the first energy rich compounds to be oxidised during respiration. Brain cells of mammals utilized only glucose as respiratory substrate. Complex carbohydrates are hydrolysed into hexose sugars before being utilized as respiratory substrates. The energy present in one gram carbohydrate is 4.4 Kcal or 18.4 kJ.
- (2) Fats: Under certain conditions (mainly when carbohydrate reserves have been exhausted) fats are also oxidised. Fat are used as respiratory substrate after their hydrolysis to fatty acids and glycerol by lipase and their subsequent conversion to hexose sugars. The energy present in one gram of fats is 9.8 Kcal or 41kJ, which is maximum as compared to another substrate.

The respiration using carbohydrate and fat as respiratory substrate, called floating respiration (Blackmann).

(3) Protein: In the absence of carbohydrate and fats, protein also serves as respiratory substrate. The energy present in one gram of protein is: 4.8 Kcal or 20 kJ, when protein are used as respiratory substrate respiration is called protoplasmic respiration.

Types of respiratory organism

Organism can be grouped into following four classes on the basis of their respiratory habit.

- Obligate aerobes: These organisms can respire only in the presence of oxygen. Thus oxygen is essential for their survival.
- (2) **Facultative anaerobes :** Such organisms usually respire aerobically (i.e., in the presence of oxygen) but under certain condition may also respire anaerobically (e.g., Yeast, parasites of the alimentary canal).
- (3) **Obligate anaerobes**: These organisms normally respire anaerobically which is their major ATP- yielding process. Such organisms are in fact killed in the presence of substantial amount of oxygen (e.g., Clostridium botulinum and C. tetani).
- (4) Facultative aerobes: These are primarily anaerobic organisms but under certain condition may also respire aerobically.

Types of respiration

On the basis of the availability of oxygen and the complete or incomplete oxidation of respiratory substrate. The respiration may be either of the following two types: Aerobic respiration and Anaerobic respiration

Aerobic respiration

It uses oxygen and completely oxidises the organic food mainly carbohydrate (Sugars) to carbon dioxide and water. It therefore, releases the entire energy available in glucose.

$$C_6H_{12}O_6 + 6O_2 \xrightarrow{\text{enzymes}} 6CO_2 + 6H_2O + \text{energy (686 Kcal)}$$

It is divided into two phases : Glycolysis, Aerobic oxidation of pyruvic acid.

Glycolysis / EMP pathway

- (1) Discovery: It was given by Embden, Meyerhof and Parnas in 1930. It is the first stage of breakdown of glucose in the cell.
- (2) **Definition**: Glycolysis (Gr. glykys= sweet, sugar; lysis= breaking) is a stepped process by which one molecule of glucose (6c) breaks into two molecules of pyruvic acid (3c).
- (3) Site of occurrence: Glycolysis takes place in the cytoplasm and does not use oxygen. Thus, it is an anaerobic pathway. In fact, it occurs in both aerobic and anaerobic respiration.

(4) Inter conversions of sugars: Different forms of carbohydrate before entering in glycolysis get converted into simplest form like glucose, glucose 6-phosphate or fructose 6-phosphate. Phosphorylation of glucose is the first step of glycolysis. Then these sugars are metabolized into the glycolysis.

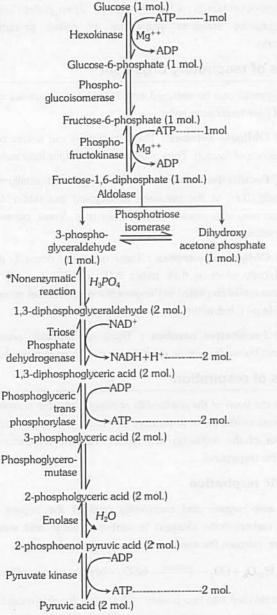

Fig: 4.4-1 Glycolysis or EMP-Pathway

- (5) Special features of glycolysis: The special features of glycolysis can be summarised as follows:
- (i) Each molecule of glucose produces 2 molecules of pyruvic acid at the end of the glycolysis.
- (ii) The net gain of ATP in this process is two ATP molecules (four ATPs are formed in glycolysis but two of them are used up in the reaction).
- (iii) During the conversion of 1, 3-diphosphoglyceraldehyde into 1, 3-diphosphoglyceric acid one molecule of $NADH_2$ is formed. As each molecule of glucose yields two molecules of 1,3-diphosphoglyceric acid, hence each molecule of glucose forms 2 molecules of $NADH_2$.

(iv) During aerobic respiration (when oxygen is available) each NADH₂ forms 3 ATP and H_2O through electron transport system of mitochondria. In this process $\frac{1}{2}O_2$ molecule is utilized for the synthesis of each water molecule.

In this way during aerobic respiration there is additional gain of 6 ATP in glycolysis

$$\begin{array}{c} 2ATP + 6ATP \\ \text{(net gain)} + 6ATP \\ \text{(addition gain)} \end{array} \rightarrow \begin{array}{c} 8ATP \\ \text{(total net gain)} \end{array}$$

- (v) Reaction of glycolysis do not require oxygen and there is no output of CO_2 .
- (vi) Formation of 1, 3- diphosphoglyceraldehyde called non enzymatic phosphorylation.
- (vii) Overall reaction of glycolysis represented by following reaction:

$$C_6H_{12}O_6 \rightarrow 2C_3H_4O_3 + 4H$$
Pyruvate

Table: 4.4-2 Total input and output materials in glycolysis

Total Input	Total Output
1 molecule of glucose (6 C)	2 molecules of pyruvate (2×3 C
2 ATP	4 ATP
4 ADP	2 ADP
2 × NAD+	2× NADH + 2H+
2 Pi	$2 \times H_2O$

Aerobic oxidation of pyruvic acid

(1) Oxidative decarboxylation of pyruvic acid: If sufficient O_2 is available, each 3-carbon pyruvate molecule $(CH_3COCOOH)$ enters the mitochondrial matrix where its oxidation is completed by aerobic means. It is called gateway step or link reaction between glycolysis and Kreb's cycle.

Decarboxylation and dehydration:

 CH_3 .CO.S.CoA+ NAD.2H + CO_2 (acetyl-S-CoA)

**TPP=Thiamine pyrophosphate

**LAA=Lipoic acid amide

Acetyl CoA is a common intermediate of carbohydrate and fat metabolism. Latter this acetyl CoA from both the sources enters Kreb's cycle. The formation of acetyle CoA is involved with some cofactors like Mg^{++} , thiamine pyrophosphate Vit B_1 , NAD^+ , CoA and lipoic acid. This reaction is not a part of Kreb's cycle.

(2) Kreb's cycle / TCA cycle / Citric acid cycle

Discovery: This cycle has been named after the German biochemist Sir Hans Krebs who discovered it in 1937. He won Noble Prize for this work in 1953. Krebs cycle is also called the citric acid cycle after one of the participating compounds. It takes place in the mitochondrial matrix.

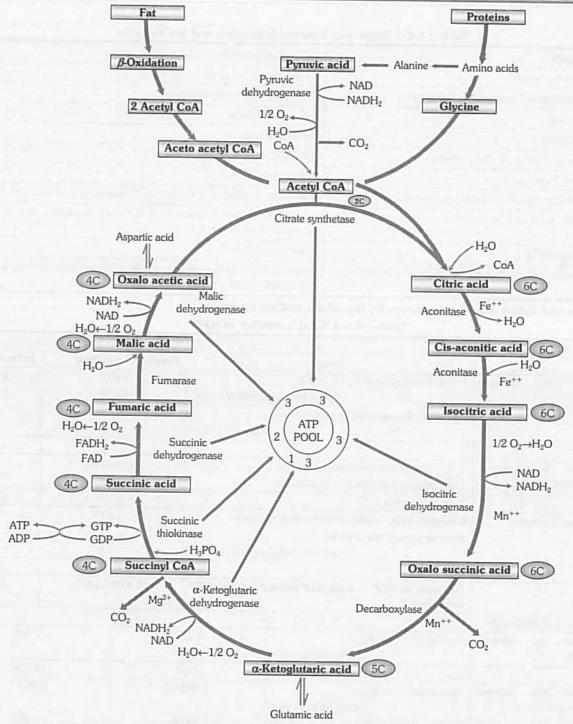

Fig: 4.4-2 Diagrammatic representation of oxidative decarboxylation of pyruvic acid and different chemical reactions in Kreb's cycle starting from Acetyl CoA

Summary of Kreb's cycle

- (i) All the enzymes, reactants, intermediates and products of TCA cycle also are found in aqueous solution in the matrix, except the succinate dehydrogenase (mitochondrial marker enzyme) which is located in the inner mitochondrial membrane.
- (ii) Oxidation of one mole of acetyl CoA uses 4 molecules of water and releases one molecule of water.
 - (iii) Liberates 2 molecules of carbon dioxide.
 - (iv) Gives off 4 pairs of hydrogen atoms.

- (v) Produces one GTP/ ATP molecule during the formation of succinate.
- (vi) One mole of acetyl CoA gives 12 ATP during oxidation in Krebs cycle.
 - (vii) Regenerates oxaloacetate used in last cycle for reuse.

The above summary is for one molecule of acetyl coenzyme A. There are two acetyl coenzyme A molecules formed from one molecule of glucose by glycolysis and oxidative decarboxylation of pyruvate.

Table: 4.4-3 Difference between Glycolysis and Kreb's cycle

Glycolysis	Kreb's cycle
It takes place in the cytoplasm.	It takes place in the matrix of mitochondria.
It occurs in aerobic as well as anaerobic respiration.	It occurs in aerobic respiration only.
It consists of 9 steps.	It consists of 8 steps.
It is a linear pathway.	It is a cyclic pathway.
It oxidizes glucose partly, producing pyruvate.	It oxidises acetyl coenzyme A fully.
It consumes 2 ATP molecules.	It does not consume ATP.
It generates 2 ATP molecules net from 1 glucose molecules.	It generates 2 GTP/ATP molecules from 2 succinyl coenzyme A molecules.
It yields 2 NADH per glucose molecule.	It yields 6 NADH molecules and 2 FADH ₂ molecules from 2 acetyl coenzyme A molecules.
It does not produce CO2.	It produces CO ₂ .
All enzyme catalysing glycolytic reactions are dissolved in cytosol.	Two enzymes of Krebs cycle reactions are located in the inner mitochondrial membrane, all others are dissolved in matrix.

Product formed during aerobic respiration by Glycolysis and Kreb's cycle. Table: 4.4-4 Total formation of ATP

Energy storage and energy transfer: In respiration energy released takes in the form of chemical energy, stored in a form called ATP. Energy transfer of biological oxidation hinges on the formation of labile high energy phosphate bonds of ATP. Nicotinamide adenine dinucleotide phosphate (NAD), Flavin adenine dinucleotide (FAD), Guanosine triphosphate are also the product of respiration and converted to ATP by electron transport system.

Adenosine triphosphate

There are several compounds like NAD, FAD, GTP and ATP are known as energy yielding compounds. The best known, and probably the most important of these are adenosine triphosphate (ATP). It serves as the energy currency of the cell.

Structure of ATP: Adenosine triphosphate is a nucleotide consisting of three main constituents;

- (i) A nitrogen contain purine base (Adenine).
- (ii) A five carbon sugar ribose.
- (ii) Three inorganic phosphate groups.

An ATP molecule is structurally most similar to a RNA molecule.

Fig: 4.4-3 Structure of ATP

The bonds attaching the last two phosphate to the rest of the molecule are high energy bonds (~) contain more than twice the energy of an average chemical bond.

ATP hydrolysis: The energy is usually released from ATP by hydrolysing the terminal phosphate groups.

Adenosine triphosphate
$$\xrightarrow{\text{hydrolysis}}$$
 Adenosine diphosphate (ADP) +Pi + 7.3Kcal.....

Adenosine diphosphate $\xrightarrow{\text{hydrolysis}}$ Adenosine monophosphate(AMP) + Pi + 7.3Kcal.

Phosphorylation: The ATP hydrolysis reactions are reversible because ATP are synthesized from ADP, Pi and energy (take up for the bond formation).

Fig: 4.4-4 Phosphorylation

The addition of phosphate group to ADP and AMP called phosphorylation. Energy required for the bond formation is equal to the energy released in hydrolysis. The significant role of ATP as an intermediate energy transfer compound.

Oxysomes acts as the unit of phosphorylation in respiration by the formation of ATP from ADP. These are present cristae of mitochondria.

Major functions of ATP: ATP molecules receive the energy, which released in exergonic reactions and make this energy available for various endergonic reactions. Some of the important process in which ATP is utilized are as follows:

- (i) Synthesis of carbohydrates, proteins, fats, etc.
- (ii) Translocation of organic food.
- (iii) Absorption of organic and inorganic food.
- (iv) Protoplasmic streaming.
- (v) Growth.

Nicotinamide adenine dinucleotide phosphate/ Nicotinamide adenine dinucleotide (NADP/NAD): It is called universal hydrogen acceptor, produced during aerobic respiration (glycolysis+ Kreb's cycle) and also in anaerobic respiration, work as coenzyme in ATP generation Via electron transport system. NADP have one additional phosphate.

NAD plays a crucial role in dehydrogenation processes. Some dehydrogenases do not work with NAD, but react with NADP (Nicotinamide adenine dinucleotide phosphate). Formerly called Coenzyme II or Triphosphopyridine nucleotide = TPN Nicotinamide is a vitamin of B group.

First NAD and NADP both functions as hydrogen acceptors. Later H ions and electrons (e-) from these are transported through a chain of carriers and after being released at the end of a chain react with O_2 and from H_2O (see Electron Transport chain). During the release of 2 electron from $2H^+$ atoms from NAD. 2H and their reaction with O_2 to form water, 3 ATP molecules are synthesized.

(3) **Electron transport system :** The electron transmitter system is also called electron transport chain (ETC), or cytochrome system (CS), as five out of these nine carriers are cytochrome. It is the major source of cells energy, in the respiratory breakdown of simple carbohydrates intermediates like phosphoglyceraldehyde, pyruvic acid, isocitric acid, α – ketoglutaric acid, succinic acid and malic acid are oxidised. The oxidation in all these brought about by the removal of a pair of hydrogen atoms (2H) from each of them. This final stage of respiration is carried out in ETS, located in the inner membrane of mitochondria (in prokaryotes the ETS is located in mesosomes of plasma membrane). The system consists of series of precisely arranged nine electron carriers (coenzyme) in the inner membrane of the mitochondrion, including the folds or cristae of this membrane. These nine electron-carriers function in a specific sequence and are:

Nicotinamide adenine dinucleotide (NAD), Flavin mononucleotide (FMN), Flavin adenine dinucleotide (FAD), Coenzyme-Q or ubiquinone, Cytochrome-b, Cytochrome- c_1 , Cytochrome-c, Cytochrome-a and Cytochrome- a_3 ,

The first carrier in the chain is a flavoprotein which is reduced by NADH₂. Coenzyme passes these electron to the cytochromes arranged in the sequence of b-c₁-c-a-a₃, finally pass the electron to molecular oxygen. In this transport, the electrons tend to flow from electro-negative to electro-positive system, so there is a decrease in free energy and some energy is released so amount of energy with the electrons goes on decreasing. During electron-transfer, the electron-donor gets oxidised, while electron-acceptor gets reduced so these transfers involve redox-reaction and are catalysed by enzymes, called reductases. Oxidation and reduction are complimentary. This oxidation-reduction reaction over the ETC is called biological oxidation.

Electron – donor $\xrightarrow{e^-}$ electron – acceptor

here, electron-donor and electron -acceptor form redox pair.

During the electron transfers, the energy released at some steps is so high that ATP is formed by the phosphorylation of ADP in the presence of enzyme ATP synthetase present in the head of F_1 -particles present on the mitochondrial cristae. This process of ATP synthesis during oxidation of coenzyme is called oxidative phosphorylation, so ETS is also called oxidative phosphorylation pathways.

From the cytochrome a_3 , two electrons are received by oxygen atom which also receives two proton (H^+) from the mitochondrial matrix to form water molecule. So the final acceptor electrons is oxygen. So the reaction

 $H_2+\frac{1}{2}\,O_2 \to H_2O$ (called metabolic water) is made to occur in many steps through ETC, so the most of the energy can be derived into a storage and usable form.

- (i) **Two route systems of ETC**: The pairs of hydrogen atoms from respiratory intermediates are received either by NAD⁺ or FAD coenzymes which becomes reduced to NADH₂ and FADH₂. These reduced coenzyme pass the electrons on to ETC. Thus, regeneration of NAD⁺ or FAD takes place in ETC. There are two routes ETC:
- (a) **Route 1**: NADH $_2$ passes their electrons to Co-Q through FAD . In route 1 FAD is the first electron carrier. 3 ATP molecules are produced during the transfer of electron on following steps:

NAD to FAD

Cyt b to Cyt c1 and

Cyt a to Cyt as

(b) Route 2 : FADH₂ passes their electron directly to FAD. 2 ATP molecules are produced during the transfer of electron on following steps.

Cyt b to Cyt c1 and

Cyt a to Cyt a3

(ii) Structure of mitochondria in relation to oxidative function: On inner side of mitochondria elementary particles or F_0 - F_1 complex of ATPase complex or elementary particle (oxysomes) are found. Previously it was considered that elementary particles contain all the enzyme of oxidative phosphorylation and electron transport chain.

Component of electron transport chain are located in the inner membrane in the form of respiratory chain complexes. For complexes following theories are given:

(a) Four complex theory: According to Devid green electron transport chain contains 4 complexes-

Complex I: Comprises *NADH* dehydrogenase and its 6 Iron Sulphur centers (Fe-S).

Complex II: Consists of Succinate dehydrogenase and its 3 Iron Sulphur centers.

Complex III: Consists of cytochrome b and c, and a specific Iron-Sulphur centers.

Complex IV: Comprises cytochromes a and a_3 .

- (b) Five complex theory : According to Hatefi, (1976), Complex I to Complex IV are related to the electron transport.
- Complex V related to mainly with ATP synthesis, so it is called ATPase /ATP synthesis complex.
- \square The head piece (F₁) of the oxysome consists of 5 hydrophobic subunits ($\alpha, \beta, \gamma, \delta, \varepsilon$), which are responsible for ATPase functioning.
- \square The stalk (F₀) contain F₅ (oligomycin sensitivity conferring protein) i.e., CSCP and F₆. F₀ are related to the proton channel and embeded fully in thickness of inner mitochondrial membrane.
- \square Five complex *i.e.*, I, II, III, IV, V, have been isolated from mitochondrial membrane by chemical treatment.

☐ Complex I : NADH/NADPH : CoQ reductase

Complex II : Succinate : CoQ reductase

Complex III: Reduced CoQ (CoQH₂): cytochrome C reductase

Complex IV: Cytochrome C oxidase

Complex V : ATPase

Cytochrome C and Q are mobile components of the respiratory chain.

(iii) Oxidative phosphorylation: The process of ATP synthesis during oxidation of reduced coenzymes in ETC is called oxidative phosphorylation.

Peter Mitchell (1961) proposed the chemiosmotic mechanism of ATP synthesis (Noble prize in 1978) which states that ATP synthesis occurs due to H^+ - flow through a membrane. It involves two steps :

- (a) Development of proton gradient. At each step of ETC, the electron-acceptor has a higher electron-affinity than the electron-donor. The energy from electron-transport is used to move the proton (H+) from the mitochondrial matrix to intermembranous or outer chamber. Three pairs of protons are pushed to outer chamber during the movement of electrons along route I while two pairs of protons are moved to outer chamber during the movement of electrons along route-II. This generates a pHgradient across the inner mitochondrial membrane with protons (H+) concentration higher in the outer chamber than in the mitochondrial matrix. This difference in H+ concentration across inner mitochondrial membrane is called protongradient(A pH). Due to proton gradient, an electrical potential $(\Delta \psi)$ is developed across the inner mitochondrial membrane as the matrix is now electronegative with respect to the intermembranous (outer) chamber. The proton gradient and membrane electric potential collectively called proton motive force.
- (b) **Proton flow**: Due to proton-gradient, the protons returns to the matrix while passing through proton channel of F_0 - F_1 ATPase. This proton gradient activates the enzyme ATP synthetase or F_0 - F_1 ATPase.

ATP synthetase controls the formation of ATP from ADP and inorganic phosphate in the presence of energy.

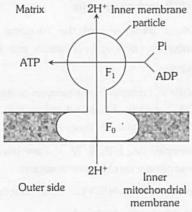

Fig: 4.4-5 ATP synthesis by inner membrane particles of mitochondria

(iv) Role of shuttle system in energy production: Glycolysis occurs in the cytoplasm outside the mitochondrion in which $2NADH_2$ molecules are produced but ETC is located along inner mitochondrial membrane, so $NADH_2$ of glycolysis must enter inside the mitochondrion to release energy. But the inner mitochondrial membrane is impermeable to $NADH_2$. In mitochondrial membrane, there are 2 shuttle-system, each formed of carrier-molecule.

These shuttle systems are:

(a) **Malate-Aspartate shuttle**: When this electron shuttle occurs, transfer of electrons from NADPH₂ in cytoplasm occurs to NAD inside the mitochondria. This is more efficient and result in production of 38 ATP molecules.

(b) **Glycerol-Phosphate shuttle**: In this shuttle transfer of electrons from $NADH_2$ in cytoplasm occurs to FAD inside mitochondria and it results in production of 36 ATP molecules. It is less efficient and results in the reduction of FAD inside the mitochondrion.

Which shuttle predominates depends on the particular species and tissues envolved, for example: 38 ATP are formed in kidney, heart and liver cell while 36 ATP molecules are formed in muscle cells and nerve cells. In these cells glycerol-phosphate shuttle is predominant and 2 ATP formed from NADH₂.

Other pathways of glucose oxidation

(1) Entner-Doudoroff pathway

Discovery: Entner-Doudoroff path discovered by Entner & Doudoroff. This pathway is also called glycolysis of bacteria.

Certain bacteria such as *Pseudomonas sacchorophila*, *P. fluorescens*, *P. lindeneri and P. averoginosa* lack phosphofructokinase enzyme. They can not degrade glucose by glycolytic process.

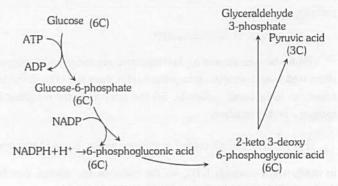

Fig: 4.4-6 Schematic representation of Entner-Doudoroff pathway

(2) Pentose phosphate pathway

- (i) **Discovery**: It is also called as Hexose monophosphate (HMP) shunt or Warburg Dickens pathway or direct oxidation pathway. It provides an alternative pathway for breakdown of glucose which is independent of EMP pathway (glycolysis) and Krebs cycle. Its existence was suggested for the first time by Warburg et al. (1935) and Dickens (1938). Most of the reaction of this cycle were described by Horecker et al. (1951) and Racker (1954).
- (ii) **Occurrence**: Pentose phosphate pathway that exists in many organisms. This pathway takes place in the cytoplasm and requires oxygen for its entire operation.
- (iii) **Description**: There are two types of evidences is support of the existence of such an alternative pathway-works on the inhibiting action of malonic acid on the Krebs cycle and studies with the radioactive (C^{14}).

UNIVERSAL BOOK DEPOT 1960

Twelve molecules of $NADH_2$ formed in the reaction can be oxidised back to 12 NADP with the help of the cytochrome system and oxygen of the air.

$$12 \text{ NADPH}_2 + 6O_2 \xrightarrow{\text{Cytochrome}} 12\text{H}_2\text{O} + 12\text{NADP}$$

In this electron transfer process, 36 molecules of ATP are synthesized.

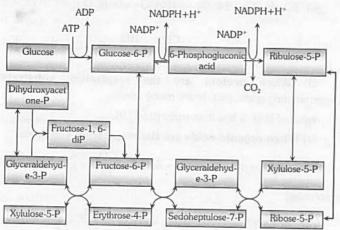

Fig: 4.4-7 Hexose monophosphate shunt

(iv) Significance of PPP

- (a) It is the only pathway of carbohydrate oxidation that gives NADPH₂, Which is needed for synthetic action like synthesis of fatty acid (in adipose tissues) and amino acids (in liver).
- (b) It synthesizes 3C-glyceraldehyde-3-P, 3C-dihydroxy acetone phosphate, 4C-erythrose-4-P, 5C-ribulose phosphate, 5C-xylulose phosphate, 5C-ribose phosphate, 6 C-Fructose 6-phosphate, 7C-sedoheptulose-7-phosphate.
- (c) It is the major pathway by which necessary ribose and deoxyribose are supplied in the biosynthesis of nucleotides and nucleic acid.
- (d) Erythrose 4 phosphate for the synthesis of lignin, oxine, anthocyanine and aromatic amino acid (phenylalanine, tyrosine, and tryptophan).
- (e) Young growing tissues appears to use to the Krebs cycle as the predominant pathway for glucose oxidation, while aerial parts of the plants and other tissues seem to utilise the PPP as well as the Krebs cycle.
 - (f) It gives 6 CO2, required for photosynthesis.
- (g) Ribulose five phosphate is used in photosynthesis to produce RuBP which act as primary CO₂ acceptor in C₃ cycle.
- (3) **Cyanide resistant pathway**: Cyanide-resistant respiration seems to be widespread in higher plant tissues. Cyanide prevents flow of electron from Cyt a_3 to oxygen, so called ETC inhibitor. In these plant tissues resistance is due to, a branch point in the ETS preceding the highly cyanide-sensitive cytochromes. The tissues lacking this branch point, or alternate pathway and blockage of cytochromes by cyanide, inhibits the electron flow.

Significance

- (i) The role of alternative pathway is that it may provide a means for the continued oxidation of NADH and operation of the tricarboxylic acid cycle, even through ATP may not be sufficiently drained off.
- (ii) It is significant in respiratory climacteric of ripening fruits and leads to the production of hydrogen peroxide and super oxide, which in turn enhances the oxidation and breakdown of membranes.
- (iii) Necessary activities in the ripening process because peroxides are necessary for ethylene biosynthesis.

Anaerobic respiration

Anaerobic respiration first studied by Kostychev (1902), Anaerobic respiration is an enzyme-controlled, partial break down of organic compounds (food) without using oxygen and releasing only a fraction of the energy. It is also called intra-molecular respiration (Pfluger, 1875). Anaerobic respiration occurs in the roots of some water-logged plants, certain parasitic worms (Ascaris and Taenia), animal muscle and some microorganisms (bacteria, moulds). In microorganisms anaerobic respiration is often called fermentation. Fermentation or anaerobic respiration is completed in cytoplasm.

Higher organism like plants can not perform anaerobic respiration for long. It is toxic because accumulation of end products, insufficient amount of available energy and causes stoppage of many active process.

Process of anaerobic respiration : In this process pyruvate which is formed by glycolysis is metabolised into ethyl alcohol or lactic acid and CO_2 in the absence of oxygen. Glycolysis is occurs in cytoplasm so the site of anaerobic respiration is cytoplasm.

$$C_6H_{12}O_6 \rightarrow 2C_2H_5OH + 2CO_2 + 52 \text{ Kcal/}218.4 \text{ kJ}$$

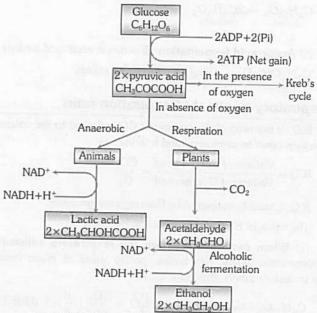

Fig: 4.4-8 Summary of anaerobic respiration pathways

(1) Formation of ethyl alcohol: When oxygen is not available, yeast and some other microbes convert pyruvic acid into ethyl alcohol.

$$2\ CH_3CHO + 2\ NADH_2 \xrightarrow{\hspace*{1cm} Alcohol\ dehy-\\ drogenase} 2C_2H_5OH + 2NAD$$

(2) Production of lactic acid: In this process hydrogen atoms removed from the glucose molecule during glycolysis are added to pyruvic acid molecule and thus lactic acid is formed.

Lactic acid is produced in the muscle cells of human beings and other animals.

Pasteur effect: The process may be defined as "the inhibition of sugar breakdown due to the presence of oxygen under aerobic condition" and the reaction is called Pasteur reaction. Dixon (1937) stated that the Pasteur effect is the action of oxygen is checking the high rate of loss of carbohydrate and in suppressing or diminishing the accumulation of products of fermentation."

Fermentation: Fermentation is a kind of anaerobic respiration carried out by microorganisms fungi and bacteria. In microorganism the term anaerobic respiration is replaced by fermentation (Cruickshank, 1897); which is known after the name of its major product, e.g., alcohol fermentation, lactic acid fermentation.

(1) Butyric acid fermentation: It occurs in bacteria Clostridium butyricum.

$$\begin{array}{c} C_6H_{12}O_6 \rightarrow C_4H_8O_2 + 2H_2 + 2CO_2 \\ \text{(hexose)} & \text{(buttyric acid)} \end{array}$$

$$2C_3H_6O_3 \rightarrow C_4H_8O_2 + 2H_2 + 2CO_2 \\ \text{(lactic acid)} \qquad \text{(buttyric acid)}$$

(2) Lactic acid fermentation: It occurs in lactic acid bacteria and muscles.

$$C_{12}H_{22}O_{11}+H_2O\rightarrow C_6H_{12}O_6+C_6H_{12}O_6 \\ \text{(glucose)} \\ \text{(galactose)}$$

$$C_6H_{12}O_6 \rightarrow 2C_3H_6O_3$$

(3) Acetic acid fermentation: It occurs in acetic acid bacteria.

$$C_2H_5OH + O_2 \rightarrow CH_3COOH + H_2O + \text{energy}$$
(ethyl alcohol) (acetic acid)

Respiratory quotient / Respiration ratio

R.Q. is the ratio of the volume of CO_2 released to the volume of oxygen taken in respiration and is written as

R.Q. =
$$\frac{Volume \ of \ CO_2 \ evolved}{Volume \ of \ O_2 \ absorbed} = \frac{CO_2}{O_2}$$

R.Q. is usually measured by Ganong's respirometer.

The value of R.Q. at compensation point is zero.

When carbohydrates are the respiratory substrate
 (=germinating wheat, oat, barley, paddy grains or green leaves kept in dark or tubers, rhizomes, etc.)

$$C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O$$
; $\frac{CO_2}{O_2} = \frac{6}{6} = 1$ (Unity)

(2) When fats are the respiratory substrate (=germinating castor, mustard, linseed, til seeds) for fatty substances R.Q. is generally less than one.

(i)
$$C_{18}H_{36}O_2 + 26O_2 \rightarrow 18CO_2 + 18H_2O$$
;
Stearic acid

$$\frac{CO_2}{O_2} = \frac{18}{26} = 0.7$$
 (Less than unity)

(ii)
$$2C_{51}H_{98}O_6 + 145O_2 \rightarrow 102CO_2 + 98H_2O$$
;

$$\frac{CO_2}{O_2} = \frac{102}{145} = 0.7$$
 (Less than unity)

(3) When protein are the respiratory substrate (=germinating gram, pea, bean, mung seeds)

value of R.Q. is less than unity (0.5-0.9).

(4) When organic acids are the respiratory substrate

(i)
$$C_4H_6O_5 + 3O_2 \rightarrow 4CO_2 + 3H_2O$$
 ; $\frac{CO_2}{O_2} = \frac{4}{3} = 1.33$ (More

than unity)

(ii)
$$2(COOH)_2 + O_2 \rightarrow 4CO_2 + 2H_2O$$
; $\frac{CO_2}{O_2} = \frac{4}{1} = 4$ (More

than unity

Some other organic acids and their R.Q. are - Succinic acid (1.14), Taurtric acid (1.6) and Acetic acid (1).

(5) When there is incomplete oxidation of carbohydrates (In the respiration of succulents i.e., Bryophyllum, Opuntia).

$$2C_6H_{12}O_6 + 3O_2 \rightarrow 3C_4H_6O_5 + 3H_2O \, ;$$

$$\frac{CO_2}{O_2} = \frac{0}{3} = 0$$
 (Zero)

(6) Respiration in the absence of O_2 (in anaerobic respiration)

$$C_6H_{12}O_6 \xrightarrow{\text{Zymase}} 2C_2H_5OH + 2CO_2$$
;

$$\frac{CO_2}{O_2} = \frac{2}{0} = \infty \text{ (Infinite)}$$

Factors affecting rate of respiration

Many external and internal factors affecting the rate of respiration are as follows:

- (1) External factors
- (i) **Temperature**: With every 10°C rise of temperature from 0°C to 30°C the rate of respiration increases 2 to 2.5 times (i.e., temperature coefficient (Q_{10}°) is = 2 to 2.5), following Vant Hoff's Law. Maximum rate of respiration takes place at 30°C , there is an initial rise, soon followed by a decline. Higher the temperature above this limit, more is the initial rise but more is the decline and earlier is the decline in the rate of respiration. Probably this is due to denaturation of enzymes at high temperature.

Below $0^{\circ}C$ the rate of respiration is greatly reduced although in some plants respiration takes place even at- $20^{\circ}C$. Dormant seeds kept at $-50^{\circ}C$ survive.

- (ii) Supply of oxidisable food: Increase in soluble food content readily available for utilization as respiratory substrate, generally leads to an increase in the rate of respiration upto a certain point when some other factor becomes limiting.
- (iii) Oxygen concentration of the atmosphere: The amount of oxygen in the environment of plants is increased or reduced upto quite low values the rate of respiration is not effected. On decreasing the amount of oxygen to 1.9% in the environment aerobic respiration become negligible (extinction point of aerobic respiration) but anaerobic respiration takes place.
- (iv) **Oxygen poisoning:** The significant fall in respiration rate was observed in many tissues in pure O_2 , even at N.T.P. This inhibiting effect was also observed in green peas when they are exposed to pure oxygen exerting a pressure of 5 atm- the respiration rate fall rapidly. The oxygen poisoning effect was reversible, if the exposure to high oxygen pressure was not too prolonged.
- (v) Water: With increase in the amount of water the rate of respiration increases. In dry seeds, which have 8-12% of water the rate of respiration is very low but as the seeds imbibe water the respiration increases. As water is necessary for activity of enzymes.
- (vi) Light: Respiration takes place in night also which shows that light is not essential for respiration. But light effects the rate of respiration indirectly by increasing the rate of photosynthesis due to which concentration of respiratory substrates is increased. More the respiratory substrate more is the rate of respiration.
- (vii) Carbon dioxide (CO_2) : If the amount of CO_2 in the air is more than the usual rate of respiration is decreased. Germination of seeds is reduced and rate of growth falls down. Heath, (1950) has shown that the stomata are closed at higher conc. of CO_2 , due to which oxygen does not penetrate the leaf and rate of respiration is lowered.
- (viii) **Inorganic salts**: The chlorides of alkali cations of Na and K, as also the divalent cations of Li, and Ca and Mg, generally increase the rate of respiration as measured by the amount of CO_2 evolved. Monovalent chlorides of K and Na increases the rate of respiration, while divalent chlorides of Li, Ca and Mg causes less increase in respiration.
- (ix) Injury and effects of mechanical stimulation : Wounding or injury almost invariably results in an increase in the rate of respiration.
- (x) Effect of various chemical substances: Certain enzymatic inhibitors like cyanides, azides, carbon monoxide, iodoacetate, malonate etc. reduce the rate of respiration even if they are present in very low concentration.

However, various chemical substances such as chloroform, ether, acetone, morphine, etc., brings about an increase in respiratory activity.

(xi) **Pollutants**: High concentration of gaseous air pollutants like SO_2 , NO_X and O_3 inhibit respiration by damaging cell membrane. These gaseous pollutant causes increase in pH which in turn affects the electron transport system thus inhibiting respiration.

Heavy metal pollutant like lead (Pb) and cadmium (Cd) inhibit respiration by inactivating respiratory enzymes.

(2) Internal Factors

- (i) Protoplasm: The meristematic cells (dividing cells of root and shoot apex) have more protoplasm than mature cells. Hence, the meristematic cells have higher rate of respiration than the mature cells. Respiration rate high at growing regions like floral and vegetative buds, germinating seedlings, young leaves, stem and root apices.
- (ii) Respiratory substrate: With the increase in the amount of respiratory substrate, the rate of respiration increases.

Tips & Tricks

- Lavosier (1783) found that respiration in animals involves intake of O_2 and liberation of CO_2 . Dutrochet is belived to have used the term of respiration for the first time, while book "cellular respiration" was written by Meldrum.
- Energesis: An old term of respiration.
- \mathcal{L} One glucose molecule contain about 686 K cal of energy and 38 ATP molecules provide 288.8 K cal of energy. Therefore about 40% (288.8/686) energy of the glucose molecule is gained during aerobic breakdown and the rest is lost as heat.
- Glucose oxidation is very rapid process of complete oxidation of a glucose molecules takes only one second.
- Phosphofructokinase called regulatory enzyme of glycolysis, it is inhibited by high concentration of ATP and is stimulated by ADP and Pi.
- Formation of 1,3-diphosphoglyceraldehyde called non enzymatic phosphorylation.
- Krebs cycle is the central pathway of the cell respiration where the catabolic pathways converge upon it an anabolic pathways diverge from it, so called amphibolic pathway.
- Acetyl Co-A, also called active acetate.
- In Kreb's cycle, acetyl CoA undergoes two decarboxylation and four dehydrogenation. Krebs cycle catabolises about 80-90% of glucose.
- $\ensuremath{\mathbf{z}}$ Allosteric inhibition or negative feedback by accumulation of NADH₂
- Ganong's respiroscope is used to demonstrate production of CO₂ during aerobic respiration.

- helps in transfer of electrons from FMNH2 to coenzyme Q. Thus, deficiency of iron direct affect ETC or oxidative phosphorylation.
- Cytochromes are Iron-containing (Iron porphyrin protein) electron transferring (electrons picked up and release by Fe) except cytochrome a3. Cytochrome a3 contains both Iron and Copper, in this Fe picks the electrons and through Cu it hands over electron to oxygen, so cytochrome a3 called terminal electron donar.

ETC inhibitors

- (i) Dinitrophenol (2,4-DNP): It prevents synthesis of ATP from ADP because it directs electrons from CoQ to O2
- (ii) Cyanide: It prevents flow of electrons from Cyt a3 to oxygen.
- (iii) Carbon monoxide: It functions like cyanide.
- (iv) Antimycin A: Transfer of electron from Cyt b to Cyt c1 is
- (v) Rotenone: It checks flow of electrons from NADH /FADH2 to CoQ.
- Action of ATPase needed Na+ and K+.
- Amount of energy released in ETC:
- (i) 12.2 Kcal during transfer of electrons from NAD to FMN.
- (ii) 15.2 Kcal during transfer of electrons from Cyt b to Cyt c.
- (iii) 24.5 Kcal during transfer of electrons from Cyt a to Cyt a3
- Glyoxylate cycle is called adaptation of Kreb's cycle.
- Effect of cyanide poisoning can be minimised by immediate supply of ATP.
- In prokaryotes aerobic cell respiration of glucose always produces 38 ATP molecules, as NADH2 molecules formed during glycolysis are not enter the mitochondria.
- Pentose phosphate pathway called connective link between photosynthesis and fat synthesis.
- The potato growing in hilly areas are bigger in size because in hilly areas temperature is low. Respiration decreases on low temperature therefore in potato complete oxidation of carbohydrate not takes place and carbohydrate/ starch in potato tuber accumulates and increases the size.
- \bowtie The R.Q. at compensation point $=\frac{CO_2}{O_2}$ = Zero (CO₂ and

O2 equal at compensation point).

- Temperature affects germinating seeds because hydration makes enzyme more sensitive to temperature.
- S Glucose before converting glycogen in muscles and liver converted into glucose 6-phosphate needed ATP. Glycogen also before utilization converted into glucose -6-phosphate process called glycogenolysis.
- Thiamine pyrophosphate is the active form of vitamin B1 (Thiamine) work as coenzyme of pyruvate carboxylase dehydrogenase.
- Climacteric fruits: Those fruits which show a high rate of respiration during their ripening e.g., Apple, Banana. In these fruits rise of respiration called climacteric rise.
- Aldolase and triose phosphate isomerase enzyme are common for EMP and C3 pathway.
- In fermentation yeast secrets the enzyme zymase.
- Universal hydrogen acceptor in NAD.

Ordinary Thinking Objective Questions

Anaerobic respiration

The energy releasing process in which the substrate is oxidised without an external electron acceptor is called

[CBSE PMT 2008; CBSE PMT (Pre.) 2010]

Lactic acid converted into alcohol in process called

[HPMT 2005; DPMT 2007]

- (a) Aerobic respiration
- (b) Glycolysis
- (c) Fermentation
- (d) Photorespiration
- During anaerobic conditions, the rate of glycolysis increases is called as

Or

The process by which there is inhibition of aerobic [DPMT 2004] respiration by atmospheric O2 is

- (a) Compensation point
- (b) Extinction point
- (c) Warburg effect
- (d) Pasteur effect
- How many ATP molecules are obtained from fermentation of 1 molecule of glucose [WB JEE 2009; KCET 2011]
 - (a) 2

(b) 4

(c) 3

- (d) 5
- In anaerobic respiration, from one glucose molecule how many net ATP molecules are formed
 - (a) 2

(b) 8

(c) 6

- (d) 4
- Pasteur effect is concerned with the shifting of [KCET 2001] environmental conditions from
 - (a) Light to dark
- (b) Aerobic to anaerobic
- (c) Anaerobic to aerobic
- (d) Light to anaerobic
- The incomplete breakdown of sugars in anaerobic respiration results in the formation of

End product of anaerobic respiration is

[AFMC 1995; RPMT 1999]

The end products of fermentation when sugars are used as [CBSE PMT 1997] raw material

- (a) Fructose and water
- (b) Glucose and CO2
- (c) Alcohol and CO2
- (d) Water and CO2
- Which of the following plant is widely accepted to respire in [MHCET 2003; MP PMT 2004] absence of oxygen
 - (a) Yeast (c) Chlorella
- (b) Potato (d) Grass
- Cyanide resistant pathway is
- [DPMT 2004] (b) Aerobic respiration
- (a) Anaerobic respiration
- (d) None of these
- (c) Both (a) and (b)
- When a molecule of pyruvic acid is subjected to anaerobic oxidation and forms lactic acid, there is
 - (a) Loss of 3 ATP molecules (b) Loss of 6 ATP molecules
 - (c) Gain of 2 ATP molecules (d) Gain of 4 ATP molecules
- During cellulose fermentation by anaerobic bacteria in rumen and reticulum, cellulose is majorly converted into

[BHU 2012]

- (a) Lactic acid
- (b) Ethyl alcohol
- (c) Volatile fatty acids
- (d) CO2

UNIVERSAL BOOK DEPOT 1960

120	(d) O ₂ is not used, CO ₂ is liberated	10.	Chemiosmotic theory of ATP synthes	sis in the chloroplasts and
19.	Anaerobic respiration was first of all reported by		mitochondria is based on	007 0005 1105
	(a) Maguenne (b) Kostychev			997, 2005; KCET 2012]
	(c) Klein (d) Pfeffer		(c) Accumulation of Na ions (d) M	ccumulation of K ions lembrane potential

Which of the option is correct for photorespiration

[GUJCET 2014]

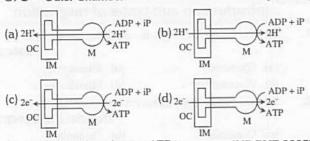

- (a) In chloroplast, glycerate forms glycine
- (b) In peroxisome, glycerate forms phosphoglycolate
- (c) In mitochondrion, glycine forms serine
- (d) In bundle sheath, serine form glycine
- Which diagram represents the ATP synthesis mitochondria through chemiosmosis

I.M = Inner membrane

M = Matrix

O. C = Outer Chamber

[NCERT]

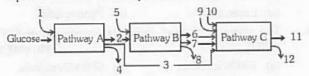

In carbon dioxide reduction ATP is 13.

[MP PMT 2005]

- (a) Used
- (b) Unused
- (c) May be used or not used (d) None
- In submerged hydrophytes entry of CO2 is through 14.

[DPMT 2004]

- (a) Epidermis as dissolved CO2
- (b) Epidermis as carbonates only
- (c) Epidermis as bicarbonates only
- (d) Both (b) and (c)
- The three boxes in this diagram represent the three major 15. biosynthetic pathways in aerobic respiration. Arrows represent net reactants or products

Arrow numbered 4, 8 and 12 can all be

INEET 2013]

- (a) FAD+ or FADH2
- (b) NADH
- (c) ATP
- (d) H₂O
- Respiration differs from the process of combustion in the fact 16.
 - (a) All the energy stored in glucose is released at once due to combustion and enzymes are involved
 - (b) All energy stored in glucose is gradually released due to combustion
 - (c) Comparatively large quantity of energy is produced due to combustion
 - (d) The carbohydrates act as the combustion substance
- 17. Adenosine diphospate contains

[CPMT 1995]

- (a) One high energy bond
- (b) Two high energy bond
- (c) Three high energy bond
- (d) Four high energy bond

- "Mitchell's chemiosmotic theory" belongs to 18.
 - (a) Kreb's cycle
 - (b) Oxidative phosphorylation
 - (c) Glycolysis
 - (d) None of the above
- Which of the following is involved in the catalysis of link 19. [DPMT 2004] reaction during aerobic respiration
 - (a) Vitamin A
- (b) Vitamin B₁
- (c) Vitamin B₆
- (d) Vitamin K
- Ganong's respiroscope is used to demonstrate..... 20.

[KCET 2004]

- (a) Production of carbon dioxide during aerobic respiration
- (b) Production of heat during aerobic respiration
- (c) Evolution of oxygen during photosynthesis
- (d) Evolution of carbon dioxide during fermentation
- ATP was discovered by 21.

[KCET 2004]

- (a) Blackman
- (b) Bowman
- (c) Lipmann
- (d) Karl Lohman
- Mechanism of aerobic respiration was discovered by 22.

[AFMC 2004]

- (a) Kreb's
- (b) Calvin
- (c) Hatch and Slack
- (d) Pasteur
- Cell respiration (Internal Respiration) is carried out by 23. [CPMT 1998; Odisha JEE 2004; Pb. PMT 2004]

Aerobic respiration which yields maximum ATP molecules is [BHU 1999] completed on

- (a) Ribosome
- (b) Mitochondria
- (c) Chloroplast
- (d) Golgi bodies
- [Pb. PMT 1999; In mitochondria, cristae act as sites for 24. AFMC 2000; CBSE PMT 2000]
 - (a) Protein synthesis
 - (b) Oxidation-reduction reaction (respiration)
 - (c) Breakdown of macromolecules
 - (d) Phosphorylation of flavoproteins
- Which of the following forms the connecting link between 25. glycolysis and Kreb's cycle [Kerala CET 2003; Wardha 2005]
 - (a) Glucose
- (b) Ethyl alcohol
- (c) Lactic acid
- (d) Pyruvic acid
- Enzymes related with cristae are related with [CPMT 1996] 26.
 - (a) Anaerobic respiration
- (b) Aerobic respiration
- (c) CO₂ formation
- (d) Reduction of pyruvic acid
- Which of the following is a more accurate statement about respiration
 - (a) O2 must always be available for respiration
 - (b) O2 combines with carbon to form CO2
 - (c) O₂ combines with hydrogen to form H₂O
 - (d) Air is inhaled and exhaled only from stomata
- In the respiratory process, energy is released and is used to synthesise energy rich molecules of ATP from ADP, thereby storing energy for future use. This process of output of these [DPMT 1993] molecules in the aerobic phase is known as
 - (a) Kreb's cycle
- (b) Glycolysis
- (c) Phosphorylation
- (d) Ornithine cycle

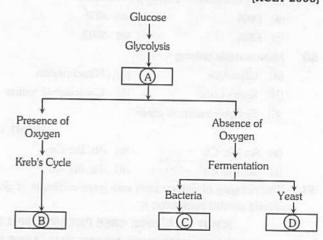

- How many ATP are formed from NADPH+ to NAD+ [KCET 2000; AFMC 2004; Bihar CECE 2006; Kerala PMT 2010; Odisha JEE 2010; J & K CET 2012] (a) 2 ATP (b) 3 ATP (c) 6 ATP (d) 4 ATP
- An ATP molecule is structurally most similar to a molecule of [Kerala CET 2003; Odisha JEE 2009] (a) RNA molecule
- (c) Amino acid
- (b) DNA molecule
- (d) Fatty acid
- 31. Aerobic respiration is called
 - (a) Fermentation
- (b) Chemosynthesis
- (c) Bio-oxidation
- (d) Photorespiration
- Which of the following is utilized first in respiration 32.

[BVP 2003]

- (a) Fat
- (b) Protein
- (c) Sucrose
- (d) Hexose
- 33. Degradation of sugar and fat to Acetyl CoA will not take place if the following organelle is not present in a eukaryotic [AIEEE Pharmacy 2003]
 - (a) Golgi apparatus
- (b) Mitochondrion
- (c) Ribosome
- (d) Nucleus
- 34. Salt respiration is also called as
- [J & K CET 2002]
- (a) Anion respiration
- (b) Cation respiration
- (c) Photorespiration
- (d) None of the above
- Leaves of annual plants obtain O2 through 35.
 - (a) Cell walls
- (b) Cuticle and leaf scars
- (c) Stomata
- (d) Lenticels
- 36. Respiratory exchange in seeds occur through
 - (a) Testa
- (b) Stomata
- (c) Micropyle
- (d) Hilum
- 37. The aerobic respiration yields
- [MHCET 2002]
- (a) 8NADH₂, 2FADH₂, 2ATP
- (b) 10NADH2, 2FADH2, 38ATP
- (c) 12NADH2, 30ATP, H2O
- (d) 10NADH2, 2FADH2, 2GTP, 2ATP
- 38. Protein is used as respiratory substrate only when
 - (a) Carbohydrates are absent
 - (b) Fats are absent
 - (c) Both exhausted
 - (d) Fats and carbohydrates are abundant
- 39. Which of the scientific paper would you assign to plant physiology
 - (a) Evergreen forest of India
 - (b) Embryo culture of plants
 - (c) Respiratory activities in plants
 - (d) Cell and cell division
- 40. Chemiosmotic mechanism of ATP synthesis was proposed by [MHCET 2001; KCET 2011]
 - (a) Warberg
- (b) Dickens
- (c) Kreb's
- (d) P. Mitchell

41. The following is a simplified scheme showing the fate of glucose during aerobic and anaerobic respiration. Identify the end products that are formed at stages indicated as A, B, C and D. Identify the correct option from those given below

- (a) A= carbon dioxide and water, B= pyruvic acid, C= ethyl alcohol and carbon dioxide, D= lactic acid
- (b) A= pyruvic acid, B= carbon dioxide and water, C= lactic acid, D= ethyl alcohol and carbon dioxide
- (c) A= pyruvic acid, B= carbon dioxide and water, C= ethyl alcohol and carbon dioxide, D= lactic acid
- (d) A= pyruvic acid, B= ethyl alcohol and carbon dioxide, C= lactic acid, D= carbon dioxide and water
- The rate of respiration could be checked by
 - (a) Malonate
- (b) CO,
- (c) Chloroform and cynides (d) All the above
- If a starved plant is provided with glucose, the rate of respiration would
 - (a) Decrease
- (b) Increase
- (c) Become constant
- (d) First rise and than fall
- The high-energy bonds of ATP are between [AIIMS 2001]
 - (a) C-C
- (b) C-O
- (c) C-N
- (d) O-P
- 45. Respiration initiated in chloroplasts and occurs in light is
 - (a) Aerobic respiration
- (b) Anaerobic respiration
- (c) Photorespiration
- (d) Fermentation
- 46. Which of the following is formed during respiration
 - [MP PMT 1999]

[J & K CET 2005]

- (a) O₂ (Oxygen)
- (b) CO2 (Carbon dioxide)
- (c) NO₂ (Nitrogen dioxide)(d) SO₂ (Sulphur dioxide)
- From substrate level phosphorylation ATP are produced [BHU 2000]
 - (a) 2

(b) 6

- (c) 10
- (d) 8
- The net gain of energy, from one molecule of sucrose in aerobic respiration, is [CBSE PMT 2001]
 - (a) 18 ATP
- (b) 38 ATP
- (c) 60 ATP
- (d) 76 ATP

Common immediate source of energy in cellular activity or Energy currency of the cell is [CPMT 1994; MP PMT 2002]

To a living organism which of the following has the greater amount of available energy per molecule

- (a) DNA
- (b) ATP
- (c) RNA
- (d) NAD
- Make suitable pairing 50.
 - (A) Glycolysis
- Mitochondria
- (B) Kreb's cycle
- (b) Cytoplasmic matrix
- (C) Electron transport chain

[RPMT 1997]

- (a) Aa, Ba, Cb
- (b) Ab, Ba, Ca
- (c) Aa, Bb, Cb
- (d) Ab. Bb. Ca
- The net gain of energy from one gram molecule of glucose 51. during aerobic respiration is

[CPMT 1996, 2002; CBSE PMT 1999; BHU 2000; KCET 2001; RPMT 2002; MP PMT 2012; AIIMS 2012]

Or

Net gain of ATP in prokaryotes from a molecule of glucose [RPMT 2005] when oxidized is

- (a) 2 ATP
- (b) 36 ATP
- (c) 38 ATP
- (d) 15 ATP
- If the CO2 content of atmosphere is as high as 300 parts per 52. million
 - (a) All plants will be killed
 - (b) The plants would not grow properly
 - (c) Plants would grow for sometime and then die
 - (d) The plants would thrive well
- Different steps in respiration are controlled by 53.

[DPMT 1992; CPMT 2002]

- (a) Auxin
- (b) Sugar
- (c) Enzyme
- (d) Kinetin
- Highest calories is obtained from

[CPMT 1996]

- (a) Fats
- (b) Proteins
- (c) Carbohydrates
- (d) Vitamins
- Aerobic respiration of glucose produces energy

[MP PMT 1993]

- (a) 637 kcal
- (b) 640 kcal
- (c) 673 kcal
- (d) 693 kcal
- 56. Cytochrome is related to
 - (a) Cellular digestion
- (b) Protein synthesis
- (c) Cell division
- (d) Cellular respiration
- [MP PMT 2005] Energy given by one molecule of ATP is 57.
 - (a) 7.3 kcal
 - (b) 721 kcal
 - (c) 760 kcal
- (d) 1000 kcal
- Respiration is an

[NCERT]

- (a) Endothermic process
- Exothermic process
- (c) Anabolic process
- (d) Endergonic process

- Who among the following can be said to be the "Father of 59. Indian Physiology"
 - (a) B.P. Pal
- (b) K.C. Mehta
- (c) M.S. Swaminathan
- (d) J.C. Bose
- The energy yield as a result of total oxidation of one glucose 60. molecule during cellular respiration is to convert

[CBSE PMT 1992]

- (a) 38 molecules of ADP into 38 molecules of ATP
- (b) 30 molecules of ADP into 30 molecules of ATP
- (c) 36 molecules of ADP into 36 molecules of ATP
- (d) 32 molecules of ADP into 32 molecules of ATP
- Cut surfaces of fruit and vegetables often become dark 61 because
 - (a) Dirty knife makes it dark
 - (b) Oxidation of tannic acid in the presence of trace of iron from the knife makes it dark
 - (c) Dust of the air makes it dark
 - (d) None of the above
- Oxidative phosphorylation occurs during the process of 62. [MP PMT 1994, 98; HPMT 2005]
 - (a) Protein synthesis
- (b) N₂ fixation
- (c) Respiration
- (d) Transpiration
- The connecting link among glycolysis, Kreb's cycle and 63. [MP PMT 1994, 98, 2001; beta-oxidation of fatty acid is

CBSE PMT 1997, 2000; BHU 2000; CPMT 2001; BVP 2001; MHCET 2004; DUMET 2010]

Or

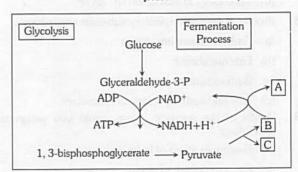

Which of the metabolites is common to respiration mediated breakdown of fats, carbohydrates and proteins [NEET 2013]

- (a) Pyruvic acid
- (b) Acetyl CoA
- (c) Acetaldehyde
- (d) Citric acid

Glycolysis

Choose the correct combination of labelling the molecules 1. involved in the pathway of anaerobic respiration in yeast

[Kerala PMT 2008; KCET 2015]

- (a) A Ethanol
- B-CO,
- C Acetaldehyde

- (b) A CO2
- B Ethanol
- C Acetaldehyde B - Acetaldehyde C - Ethanol
- (c) A CO2
- (d) A Acetaldehyde B CO2
- C Ethanol

- (e) A Ethanol
- B Acetaldehyde C CO2

LINIVI	RSA	
		Transcore

2.	In which of the following reaction of gl	lycolysis,	a molecule
	of water is removed from the substrate	[Kerala	PMT 2008]

- (a) Fructose 6 phosphate → fructose 1, 6 bisphosphate
- (b) 3 phosphate glyceraldehyde $\rightarrow 1$, 3-bisphosphoglyceric acid
- (c) PEP → pyruvic acid
- (d) 2 Phosphoglycerate → PEP
- (e) Glucose → glucose 6 phosphate
- 3. Which process does the following equation represent $C_6H_{12}O_6 + 2NAD + 2ADP + 2Pi$

 \rightarrow 2CH₃ - CO - COOH + 2NADH₂ + 2ATP

[MHCET 2015]

- (a) Complete glycolysis
- (b) Complete aerobic respiration
- (c) Complete anaerobic respiration
- (d) Complete fermentation
- How many ATP are used in glycolysis or For complete 4. phosphorylation of a glucose molecule, how many ATP molecules are required

The net gain of ATP during glycolysis is

[KCET 2007]

(a) 4

(b) 2

(c) 6

- (d) 8
- 5. Which of the following substances yield less than 4 Kcal/mol when its phosphate bond is hydrolysed [WB JEE 2009]
 - (a) Creatine phosphate
- (b) ADP
- (c) Glucose-6-phosphate
- (d) ATP
- 6. Which is not true for glycolysis [NCERT; Manipal 2005]
 - (a) End product is CO2, H2O
 - (b) Substrate level phosphorylation
 - (c) Production of ATP
 - (d) Expenditure of ATP
- 7. Glycolysis term has originated from Greek words

[NCERT; AMU (Med.) 2012]

- (a) Glycose and lysis
- (b) Glycos and lysis
- (c) Glyco and lysis
- (d) Glucose and lysis
- 8. Consider the following statements with respect to respiration
 - A. Glycolysis occurs in the cytoplasm of the cell
 - B. Aerobic respiration takes place within the mitochondria
 - C. Electron transport system is present in the outer mitochondrial membrane
 - D. $C_{51}H_{98}O_5$ is the chemical formula of Tripalmitin, a fatty acid
 - E. Respiratory quotient = $\frac{Volume \, O}{Volume \, of \, CO_2 \, consumed}$

Of the above statements

[Kerala PMT 2012]

- (a) A, B, and D alone are correct
- (b) B, C and D alone are correct
- (c) C, D and E alone are correct
- (d) B, D and E alone are correct
- (e) A, C and E alone are correct

9. Decarboxylation is not involved in [DPMT 2004]

- (a) Electron transport system (b) Glycolysis
- (c) Kreb's cycle
- (d) Alcoholic fermentation
- Which one is correct sequence in glycolysis [MHCET 2004] 10.
 - (a) G 6-P \rightarrow PEP \rightarrow 3-PGAL \rightarrow 3-PGA
 - (b) G 6-P \rightarrow 3-PGAL \rightarrow 3-PGA \rightarrow PEP
 - (c) G 6-P \rightarrow PEP \rightarrow 3-PGA \rightarrow 3 PGAL
 - (d) G 6-P \rightarrow 3-PGA \rightarrow 3-PGAL \rightarrow PEP
- 11. In glycolysis, during oxidation electrons are removed by

[CBSE PMT 2004]

- (a) NAD+
- (b) Molecular oxygen
- (c) ATP
- (d) Glyceraldehyde-3-phosphate
- In glycolytic pathway which of the following steps shows reduction of co-enzyme [Odisha JEE 2010]
 - (a) 1, 3-diphosphoglycerate to 3-phosphoglycerate
 - (b) Glucose 6-phosphate to fructose 6-phosphate
 - (c) Glyceraldehyde 3-phosphate to 1,3-diphosphoglycerate
 - (d) 3-phosphoglycerate to 2-phosphoglycerate
- 13. First stage in respiration is
 - (a) Aerobic oxidation of pyruvic acid
 - (b) Liberation of CO,
 - (c) Glycolysis
 - (d) Electron transport system
- Besides the net gain of 2 ATP molecules in glycolysis which other molecules are simultaneously formed
 - (a) FADH_o
- (b) NADPH,
- (c) NADH₂
- (d) FAMH,
- Which of the following is the product of phosphorylation 15.
 - (a) PGA
- (b) Fructose 1, 6 diphosphate
- (c) DPGA

- (d) Pyruvic acid
- In glycolysis, the end product is

[NCERT; CPMT 1996, 2001, 03 MP PMT 1996, 2003; KCET 1998; MHCET 2001; PET (Pharmacy) 2013]

- (a) Protein is converted to glucose
- (b) Glucose is converted into fructose
- (c) Starch is converted into glucose
- (d) Glucose is converted into pyruvic acid
- Total ATP production during EMP pathway is

[CBSE PMT 1990]

- (a) 24 ATP molecules
- (b) 8 ATP molecules
- (c) 38 ATP molecules
- (d) 6 ATP molecules
- Glycolysis (EMP Pathway) takes place in

[KCET 1994; MP PMT 1996, 2004, 05; BVP 2001; Odisha PMT 2002; RPMT 2002; CPMT 2004; Bihar CECE 2006; Odisha JEE 2008; J & K CET 2012]

Anaerobic respiration takes place in the

[DPMT 1992; MP PMT 2002, 06]

- (a) Mitochondria
- (b) Cytoplasm
- (c) Both mitochondria and cytoplasm
- (d) Vacuole

- Which one of the following is the first step of glycolysis [NCERT: DPMT 2004]
 - (a) Breakdown of glucose
 - (b) Phosphorylation of glucose
 - (c) Conversion of glucose into fructose
 - (d) Dehydrogenation of glucose
- [NCERT; BVP 2001; AFMC 2003] 20. Glycolysis occurs in

 - (a) Generally in all the cells (b) In only eukaryotes
 - (c) Only in prokaryotes
- (d) Only in higher animals
- 21. The number of molecules of pyruvic acid formed from one molecule of glucose at the end of glycolysis is

(b) 2

(c) 3

- What is the other name of glycolysis 22.
 - [Pune CET 1998; CPMT 1998]
 - (a) EMP pathway
- (b) TCA pathway
- (c) HMS pathway
- (d) None of the above
- 23. During respiration [GUJCET 2015]
- - (a) 2 PGAL during glycolysis and none of the PGAL produced in Kreb's cycle
 - (b) 2 PGAL during glycolysis and 4 Pyruvic acid are produced in Kreb's cycle
 - (c) 2 PGAL during glycolysis and 2 Pyruvic acid are produced in Kreb's cycle
 - (d) PGAL is not produced during respiratory events
- During respiration, pyruvic acid is formed by

[BHU 1995; MP PMT 2011]

Or

The first phase in the breakdown of glucose in animal cells is

[BVP 2002; AIEEE Pharmacy 2004]

- (a) Glycolysis
- (b) Kreb's cycle
- (c) HMP pathway
- (d) None of the above
- 25. The common phase between aerobic and anaerobic respiration is called -[NCERT;

MP PMT 1992, 2009; BHU 2008]

- (a) Tricarboxylic acid cycle
- (b) Oxidative phosphorylation
- (c) Embden, Meyerhof, Parnas cycle (Glycolysis)
- (d) Kreb's cycle
- [KCET 1994] 26. The formula for the process of glycolysis is
 - (a) $C_6H_{12}O_6 \rightarrow 2C_3H_4O_3 + 4H$
 - (b) $C_6H_{12}O_6 + 6CO_2 \rightarrow 6CO_2 + 6H_2O$
 - (c) $6H_2O + 6CO_2 \rightarrow C_6H_{12}O_6 + 6O_2$
 - (d) None of these
- Which group of the following scientists discovered the EMP pathway of glycolysis [NCERT; MP PMT 1995; BVP 2002]
 - (a) Embden, Meyerhof and Parnas
 - (b) Emerson, Hoffman and Peterson
 - (c) Embden, Morrison and Pitcher
 - (d) Avery, McLeod and McCarthy

- Which one of the following products is formed during glycolysis of glucose [MP PMT 1995, 2000, 02; AIIMS 2002]
 - (a) Pyruvic acid
- (b) Carbon dioxide
- (c) Citric acid
- (d) Ethanol
- Column I contains some enzymes and Column II contains reactions. Match them properly and choose the right answer

IMP PMT 1996: AIIMS 1999: Ph PMT 1999, 20001

	Column I		Column II
A.	Hexokinase	1.	Conversion of fructose-6- phosphate to fructose-1-6- diphosphate
B.	Triose Phosphate dehydrogenase	2.	Conversion of glucose to glucose-6-phosphate
C.	Phosphoglycero- mutase	3.	Conversion of 1, 3-diphosphoglyceraldehyde to 1, 3-diphosphoglyceric acid
D.	Phosphofructo- kinase	4.	Conversion of 3- phosphoglyceric acid to 2- phosphoglyceric acid

- (a) A-1, B-2, C-3, D-4
- (b) A-2, B-3, C-4, D-1
- (c) A-2, B-1, C-3, D-4
- (d) A-1, B-5, C-2, D-4
- ATP formation in glycolysis is 30.

[AMU (Med.) 2006; MP PMT 2012]

- (a) Oxidative phosphorylation
- (b) Photophosphorylation
- (c) Reductive phosphorylation
- (d) Substrate level phosphorylation
- Given below are some reactions and the enzymes involved. 31.

Identify the correct pairs

I		II		
1.	Fructose 1,6 diphosphate → 3 PGAL + DHAP	A.	Enolase	
2.	Citrate → Cis – aconitate	B.	Thiokinase	
3.	Succinyl Co. A → Succinate	C.	Aconitase	
4.	2 PGA → PEPA	D.	Aldolase	

[MHCET 2015]

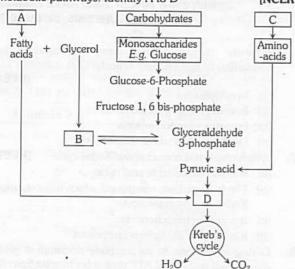

- (a) 1-D, 2-C, 3-B, 4-A
- (b) 1-A, 2-B, 3-C, 4-D
- (c) 1-B, 2-A, 3-D, 4-C
- (d) 1-C, 2-D, 3-A, 4-B
- In muscles from three molecules of glucose, two are 32. completely oxidized and one is incompletely oxidized (anaerobic) then, what will be the number of total NAD+ [GUJCET 2014] molecules utilized
 - (a) 10
- (b) 20
- (c) 14
- (d) 08
- Which of the following process occurs in glycolysis 33.

[JIPMER 2002]

- (a) Oxidation
- (b) Reduction
- (c) Hydrogenation
- (d) Fixation

UNIVERSAL ROOK DEPOT 195

The given figure indicates the interrelationship among metabolic pathways. Identify A to D [NCERT]

	Α	В	С	D
(a)	Fat	DHAP	Acetyl CoA	Protein
(b)	Acetyl CoA	Fat	DHAP	Protein
(c)	Fat	DHAP	Protein	Acetyl CoA
(d)	Protein	Acetyl CoA	Fat	DHAP

35. Glucose is

[MP PMT 2013]

- (a) Pyranose pentose sugar (b) Furanose pentose sugar
- (c) Ketose hexose sugar
- (d) Aldose hexose sugar
- 36. Which of the following biomolecules is common to respiration-mediated breakdown of fats, carbohydrates and proteins [NEET (Phase-II) 2016]
 - (a) Acetyl CoA
 - (b) Glucose-6-phosphate
 - (c) Fructose 1, 6-bisphosphate
 - (d) Pyruvic acid

Kreb's cycle and ETS

The details of tricarboxylic acid path was worked out by

[Odisha JEE 2008; AFMC 2012]

- (a) Meischer
- (b) Hans Krebs
- (c) Pasteur
- (d) None of these
- 2. The product formed by malic dehydrogenase is
 - (a) Malic acid
- (b) Fumaric acid
- (c) Oxaloacetic acid
- (d) Succinic acid
- During Krebs' cycle energy from glucose is mostly 3. transferred to [Odisha JEE 2009]
 - (a) NADH & FADH
- (b) NADPH
- (c) ADP
- (d) Water
- 4. The number of carbon atom in citric acid is

[Odisha JEE 2008]

(a) 8

(b) 6

(c) 10

- (d) 2
- 5. Hydrogen of malate is accepted by
 - (a) FAD
- (b) FMN
- (c) COQ
- (d) NAD

- During aerobic respiration maximum ATP is synthesized by 6. [Odisha JEE 2009]
 - (a) ETS
- (b) Krebs' cycle
- (c) Glycolysis
- (d) Fermentation
- 7. Which one of the following is complex V of the ETS of inner mitochondrial membrane [Kerala PMT 2009]
 - (a) NADH dehydrogenase
- (b) Cytochrome c oxidase
- (c) Ubiquinone
- (d) Succinate dehydrogenase
- (e) ATP synthase
- 8. Which intermediate compound is involved in the synthesis of amino acids
 - (a) Malic acid
- (b) Citric acid
- (c) α-ketoglutaric acid
- (d) Isocitric acid
- 9. During one Krebs' cycle number of CO2 molecules released [MH CET 2005; AMU (Med.) 2009] is
 - (a) 1

(c) 3

- (d) 4
- During movement of electron through ETC [BHU 2012]
 - (a) pH of matrix increases
 - (b) Electrons are transported by active transport
 - (c) Electrons are resonated
 - (d) Electrons show fluorescence
- In citric acid cycle decarboxylation occurs when

[AMU (Med.) 2010]

- (a) Citric acid converts to α ketoglutaric acid
- (b) Succinic acid converts to malic acid
- (c) Malic acid converts to oxaloacetic acid
- (d) Oxaloacetic acid converts to citric acid
- The overall goal of glycolysis, Krebs cycle and the electron 12. transport system is the formation of [CBSE PMT 2007]
 - (a) ATP in small stepwise units
 - (b) ATP in one large oxidation reaction
 - (c) Sugars
 - (d) Nucleic acids
- In the electron transport system present in the inner mitochondrial membrane, complexes I and IV are respectively [Kerala PMT 2011]
 - (a) NADH dehydrogenase and FADH 2
 - (b) FADH2 and NADH dehydrogenase
 - (c) NADH dehydrogenase and cytochrome oxidase complex
 - (d) NADH dehydrogenase and ATP synthase
 - (e) Cytochrome bc 1 complex and NADH dehydrogenase
- Kreb's cycle was discovered by Krebs in pigeon muscles in 1940. Which step is called gateway step. Link reaction/transition reaction in respiration

[NCERT: AFMC 2006]

- (a) Glycolysis
- (b) Formation of acetyl-coA
- (c) Citric acid formation
- (d) ETS terminal oxidation
- 15. In Kreb's cycle formation of
 - [RPMT 2001, 06; Bihar CECE 2006]
 - (a) 34 ATP takes place
 - (b) 38 ATP takes place
 - (c) 15 ATP from each acetyl Co-A takes place
 - (d) 12 ATP from each acetyl Co-A takes place (24 ATP)

17.

716 Respiration in Plants

- All enzymes of TCA cycle are located in the mitochondrial matrix except one which is located in inner mitochondrial membranes in eukaryotes and in cytosol in prokaryotes. This enzyme is [AIIMS 1994; CBSE PMT 2007]

 - (a) Lactate dehydrogenase (b) Isocitrate dehydrogenase
 - (c) Malate dehydrogenase Cytochrome oxidase is a/an
- (d) Succinate dehydrogenae [MP PMT 2007]
- (a) Exoenzyme
- (b) Endoenzyme
- (c) Proenzyme
- (d) Coenzyme
- 18.
- Synthesis of ATP in mitochondria require
- (a) Oxygen
- (b) NADP
- (c) FMN
- (d) Pyruvic acid
- Which of these steps in Kreb's cycle indicates substrate level phosphorylation [Kerala PMT 2011]
 - (a) Conversion of succinic acid to α ketoglutaric acid
 - (b) Conversion of succinic acid to malic acid
 - (c) Conversion of succinyl Co. A to succinic acid
 - (d) Conversion of malic acid to oxalo acetic acid
 - (e) Conversion of citric acid to α ketoglutaric acid
- 20. Most of the energy in the cell is liberated by oxidation of carbohydrate when
 - (a) Pyruvic acid is converted into CO2 and H2O
 - (b) Pyruvic acid is converted into Acetyl CoA
 - (c) Sugar is converted into pyruvic acid
 - (d) Glucose is converted in alcohol and CO2
- Complete oxidation of 1 gm molecule of glucose gives rise to 21.
 - [RPMT 1997]

- (a) 68,60,000 cal
- (b) 6,86,000 cal
- (c) 68,600 cal
- (d) 6,800 cal
- 22. Pyruvic acid is converted into a compound before formation of oxaloacetic acid in the citric acid cycle, this compound is

[MP PMT 2002]

Or

Which of the following metabolites enter the TCA cycle during glucose oxidation [WB JEE 2016]

- (a) Acetyl CoA
- (b) Acetoacetic acid
- (c) Lactic acid
- (d) cis aconitic acid
- In respiration, pyruvic acid is 23.
 - (a) Formed only when oxygen is available
 - (b) One of the product of Kreb's cycle
 - (c) Broken down into two carbon fragments and CO2
 - (d) A result of protein breakdown
- Match the number of carbon atoms given in List I with that of the compounds given in List - II and select the correct ontion

	List - I	l into	List - II	
A.	4C Compound	1.	Acetyl CoA	
B.	2C Compound	2.	Pyruvate	
C.	5C Compound	3.	Citric acid	
D.	3C Compound	4.	α – keto glutaric acid	
	Andrews S. Lin	5.	Malic acid	

[NCERT; Kerala PMT 2007, 08]

- (a) A-2, B-5, C-3, D-1 (b) A-5, B-1, C-4, D-2
- (c) A-3,B-1,C-4,D-2 (d) A-5,B-3,C-1,D-2
- (e) A-3, B-4, C-1, D-5
- 25. In Kreb's cycle OAA accepts acetyl CoA to form

[Odisha JEE 2010]

- (a) Citric acid
- (b) Oxalosuccinate
- (c) Fumarate
- (d) Succinyl CoA

The reaction of Kreb's cycle (TCA cycle) take place 26.

[CPMT 1994; CBSE PMT 1996; MP PMT 1997; BVP 2001: JIPMER 2001; MHCET 2002; AIEEE Pharmacy 2003; Odisha JEE 2005, 10, 12; KCET 2012]

Or

Pyruvate dehydrogenase complex, needed for the conversion of pyruvic acid to acetyl CoA is located in

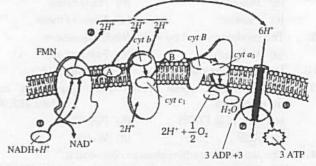

[KCET 2010]

- (a) In cytoplasm
- (b) In endoplasmic reticulum
- (c) In matrix of mitochondria
- (d) On the surface of mitochondrion
- 27. Which one is not correct about Krebs' cycle [KCET 2007]
 - (a) It is also called citric acid cycle
 - (b) The intermediate compound which links glycolysis with Krebs' cycle is malic acid
 - (c) It occurs in mitochondria
 - (d) It starts with six carbon compound
- 28. During which stage in the complete oxidation of glucose are the greatest number of ATP molecules formed from ADP [CBSE PMT 2005]

Or

Largest amount of phosphate bond energy is produced in the process of respiration during IBHU 20021

- (a) Conversion pyruvic acid to acetyl CoA
- (b) Electron transport chain
- (c) Glycolysis
- (d) Kreb's cycle
- Choose the correct statement
- [KCET 2015]
- (a) Oxygen is vital in respiration for removal of Hydrogen
 - (b) Pyruvate is formed in the mitochondrial matrix
 - (c) There is complete breakdown of glucose in fermentation
 - (d) During the conversion of Succinyl CoA to Succinic acid a molecule of ATP is synthesized
- 30. In Kreb's cycle the hydrogen atoms removed at succinate level are accepted by
 - (a) FAD
- (b) ADP
- (c) ATP
- (d) NAD
- The following is a scheme showing the electron transport system. Identify the electron carrier molecules indicated as A and B. Choose the correct option [KCET 2010]

- NADH dehydrogenase
- Cytochrome b-c1 complex
- Cytochrome oxidase
- Synthase
- (a) A = coenzyme Q, B = cytochrome c
- (b) A = cytochrome c, B = coenzyme Q
- (c) A = Fe-S protein, B = FMN
- (d) A = FMN, B = Fe-S protein

32.	Ox	idative phosphorylation occurs in
		[RPMT 1995; Pune CET 1998; JIPMER 2001]
	(a)	Outer membrane of mitochondria
	(b)	Inner membrane of mitochondria
	(c)	Stroma of chloroplast
	(d)	Grana of chloroplast
22	The	on sum on for all all and a later to the state of the sta

The enzymes for electron transport system are located in the [Kerala PMT 2004] Or

Cellular energy is provided through respiration and oxidation by

- (a) Plastid
- (b) Endoplasmic reticulum
- (c) Ribosomes (e) Golgi bodies
- (d) Mitochondria
- 34. Respiratory enzymes are located in

[RPMT 1995; Bihar MDAT 1995; MP PMT 2001; AFMC 2003; AMU (Med.) 2005;

- BHU 2008; WB JEE 2009; Odisha JEE 2011] (a) Mitochondrial matrix (mitochondria)
- (b) Perimitochondrial space
- (c) Cristae
- (d) Outer membrane
- Food is converted to energy in 35.
 - (a) Chloroplast
- (b) Nucleus
- (c) Mitochondria
- (d) None of the above
- 36. ATP molecules produced respectively by NADH(H+) and FADH₂ during electron transport are [MP PMT 2013]
 - (a) 3 and 2
- (b) 1 and 1
- (c) 2 and 3
- (d) 3 and 3
- 37. Which of the following is correct sequence in Kreb's cycle
 - (a) Isocitric acid → Oxalosuccinic acid → α-ketoglutaric acid
 - (b) Oxalosuccinic acid → Isocitric acid α-ketoglutaric acid
 - (c) α-ketoglutaric acid → Isocitric acid → Oxalosuccinic acid
 - (d) Isocitric acid $\rightarrow \alpha$ -ketoglutaric acid \rightarrow Oxalosuccinic acid
- 38. In how many steps, CO2 is released in aerobic respiration of pyruvic acid
 - (a) One
- (b) Six
- (c) Three
- (d) Twelve
- 39. Activity of succinic dehydrogenase involves the following in TCA cycle [DPMT 2004]
 - (a) NAD
- (b) FAD
- (c) GDP
- (d) ATP
- 40. The formation of acetyl coenzyme-A from pyruvic acid is the result of its [Kerala PMT 2004; AFMC 2009; KCET 2011]
 - (a) Reduction
 - (b) Dehydration
 - (c) Dephosphorylation
 - (d) Oxidative decarboxylation
- 41. Oxidation of succinate to fumerate in the Kreb's cycle is due to
 - (a) Loss of electron from it
 - (b) Removal of hydrogen from it
 - (c) Addition of oxygen to it
 - (d) None of the above

- 42. Oxidative phosphorylation and photophosphorylation both require the electron carrier
 - (a) Cytochrome
- (b) Oxygen
- (c) Carbon dioxide
- (d) Water
- Cytochrome helps in
- [AFMC 1994; MP PMT 1996]
- (a) Oxidation of glucose
- (b) Release of energy
- (c) Electron transport
- (d) Growth
- In oxidative photophosphorylation, the last 3 steps are as follows [Odisha JEE 2004]
 - $Q \rightarrow C \rightarrow aa_3 \rightarrow O_2$
 - (a) $Q \rightarrow C$ is H^+ absorbing site
 - (b) $aa_3 \rightarrow O_{2+}H^+$ yielding site
 - (c) $Q \rightarrow C$ is H^+ yielding site and $aa_3 \rightarrow O_2$ is H^+ absorbing site
 - (d) No H+ is absorbed or released
- In which one of the following do the two names refer to one and the same thing [CBSE PMT 2003]
 - (a) Tricarboxylic acid cycle and urea cycle
 - (b) Kreb's cycle and Calvin cycle
 - (c) Tricarboxylic acid cycle and citric acid cycle
 - (d) Citric acid cycle and Calvin cycle
- By the reaction of α -ketoglutaric acid with ammonia, 46. through which of the process glutamic acid is formed

[GUJCET 2007]

- (a) Oxidative amination
- (b) Reductive amination
- (c) Ammonification
- (d) Transamination
- Biological oxidation in Kreb's cycle involves
 - [MP PMT 1994; Odisha JEE 2011]
 - (a) No
- (b) CO,
- (c) O₂
- (d) SO,
- Oxidative phosphorylation is the formation of

[CBSE PMT 1992, 96; BHU 1994, 99; Odisha JEE 2009]

- (a) NADPH2 in respiration
- (b) ATP in respiration
- (c) NADPH2 in photosynthesis
- (d) ATP in photosynthesis
- Mineral activator needed for the enzyme carboxylase of TCA cycle is
 - (a) Mg++
- (b) Fe+++
- (c) Mo++
- (d) Mn++
- 50. Kreb's cycle involves the formation of
 - (a) Lactic acid from glucose
 - (b) Change of pyruvic acid to energy transformation
 - (c) Pyruvic acid from glucose
 - (d) ATP from ADP
- 51. In the electron transport system, the reduced coenzymes are regenerated by
 - (a) Loss of hydrogen
- (b) Loss of electron
- (c) Addition of oxygen
- (d) None of the above

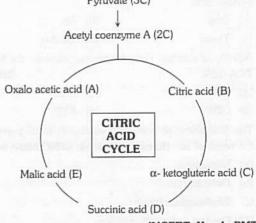

718 Respiration in Plants Which of the following does not function as an electron 52. [Kerala PMT 2004] (b) Cytochrome-c (a) Coenzyme Q (c) Cytochrome-a (d) Cytochrome-a₃ (e) H₂O 53. Kreb's cycle begins with [CBSE PMT 1991] (b) Hydrochloric acid (a) Pyruvic acid (c) Corticosteroids (d) Lysine In ETS, electron combines to [CPMT 1994] 54. (a) Cytochrome (b) H₂ (c) O2 (d) H₂O How many ATP molecules could maximally be generated 55. from one molecule of glucose, if the complete oxidation of one mole of glucose to CO2 and H2O yields 686 kcal and the useful chemical energy available in the high energy phosphate bond of one mole of ATP is 12 kcal [CBSE PMT 2006] (b) One (a) Fifty-seven (d) Thirty Each molecule of pyruvic acid entering the Kreb's cycle 56. produces (a) 2 molecules of CO2 (b) 3 molecules of CO2 (c) 1 molecules of CO2 (d) 5 molecules of CO2 The last or terminal cytochrome in respiratory chain is [CBSE PMT 1992; RPMT 1997] Or In an electron transport chain in terminal oxidation the cytochrome which donates electrons to O2 is (a) Cyt b (b) Cyt a₃ (c) Cyt a (d) Cyt c Upon the oxidation of one mole of pyruvate by 58. mitochondrial respiration, the moles of ATP generated are [BHU 1994; KCET 1998] (a) 38 (b) 30 (d) 15 (c) 8 Kreb's cycle is also called [EAMCET 1995; MHCET 2003; WB JEE 2009] (a) TCA cycle (b) Citric acid cycle (c) Tricarboxylic cycle (d) All the above 60. Kreb's cycle is found in [AFMC 1996] (a) Anaerobic respiration (b) Photorespiration (c) Photosynthesis (d) Aerobic respiration The importance of Kreb's cycle is in the production of 61. [MP PMT 1996] (a) Acetyl CoA (b) Water (d) ADP (c) ATP The correct sequence of electron acceptor in ATP synthesis is 62. [CBSE PMT 1997; MHCET 2002, 06] (b) Cytbcaa3 (a) Cytaabc (d) Cytcbaa3 (c) Cytbca3 a In Kreb's cycle, the FAD participates as electron acceptor during the conversion of [CBSE PMT 1997; MHCET 2002; AMU (Med.) 2009; WB JEE 2009; AFMC 2010] (a) Succinyl CoA to succinic acid

> (b) α-ketoglutarate to succinyl CoA (c) Fumaric acid to malic acid

(d) Succinic acid to fumaric acid

Which transfer electrons in E.T.S. (Electron Transport System) [CPMT 1998] (b) F₁ particles (a) Phytochrome (d) None of these (c) Fe-S The pyruvic acid formed in Glycolysis is oxidised to CO2 65. [NCERT; MP PMT 1999; and H_2O in a cycle called J & K CET 2008] (a) Calvin cycle (b) Hill reaction (c) Kreb's cycle (d) Nitrogen cycle Which one of the following energy storing compound is formed when succinyl CoA is converted into succinic acid [BHU 2000] (b) ATP (a) ADP (c) AMP (d) GTP 67. Which of the following is not an electron transferring molecule [KCET 2001] (a) ATP (b) NAD+ (d) Co-enzyme Q (c) Fe-S protein [CBSE PMT 2001] Cytochromes are (a) Lipid (b) Glycoprotein (c) Metalloporphyrins (d) Fe++ containing with porphyrin pigment 69. Cytochromes occur in [BHU 2001; AIPMT (Cancelled) 2015] (a) Cristae of mitochondria (b) Matrix of mitochondria Outer mitochondrial membrane (d) Entire inner mitochondrial membrane Final electron acceptor in ETS is [Kerala CET 2002; CPMT 2003; BHU 2004; RPMT 2006; Odisha JEE 2009; MH CET 2015] (b) O2 (a) H₂O (d) Cyt a (c) Cyt a₃ Choose the correct combination of labelling the number of carbon compounds in the substrate molecules, involved in the citric acid cycle Pyruvate (3C) Acetyl coenzyme A (2C)

[NCERT; Kerala PMT 2006]

- (a) (A) 4C, (B) 6C, (C) 5C, (D) 4C, (E) 4C

- (e) (A) 4C, (B) 6C, (C) 4C, (D) 4C, (E) 4C

OOK DEPOT 196

[AFMC 1993;

[CPMT 1994]

(b) 0.75

(d) 3.00

Oxidative phosphorylation is [NEET (Phase-II) 2016] HMP shunt is a set of reactions (a) Formation of ATP energy released from electrons (a) Called pentose phosphate pathway removed during substrate oxidation (b) Which bypasses EMP route of glucose oxidation (b) Formation of ATP by transfer of phosphate group from (c) Either of the above a substrate to ADP (d) Which converts glucose to phosphoglycerate (c) Oxidation of phosphate group in ATP 9. Pentose phosphate pathway, an alternative pathway of (d) Addition of phosphate group to ATP respiration was elucidated by Which statement is wrong for Krebs' cycle (a) Horecker 73. (b) Warburg and Dickens [NEET 2017] (c) Blackman (d) Kelvin (a) There are three points in the cycle where NAD+ is 10. In hexose monophosphate shunt, the number of CO2 reduced to NADH+H+ molecules evolved is (b) There is one point in the cycle where FAD+ is reduced (a) Same as in glycolysis to FADH, (b) Less than glycolysis (c) During conversion of succinyl CoA to succinic acid, a (c) More than glycolysis molecule of GTP is synthesised (d) Much lesser than glycolysis (d) The cycle starts with condensation of acetyl group Which of the following is produced in oxidative pentose 11. (acetyl CoA) with pyruvic acid yield citric acid phosphate pathway [Kerala PMT 2007] (a) Pyruvic acid Pentose phosphate pathway (b) Acetyl CoA (c) NADH, (d) NAD(P)H The reactions of pentose phosphate pathway (PPP) take 1. (e) ATP place in [Kerala PMT 2009] R.Q. (a) Mitochondrion 1. (b) Cytoplasm R.Q. for glucose (Carbohydrates) is CPMT 1998; Bihar CECE 2005; J & K CET 2008] (c) Chloroplast, peroxisome and mitochondrion (a) 1 (b) 0.5 (d) Chloroplast, glyoxysome and mitochondrion (c) 2 (d) 0.05 (e) Chloroplast, lysosome and mitochondrion 2. If R. Q. is less than 1.0 in a respiratory metabolism, it would Which of the following is a direct oxidation pathway being 2. mean that [Kerala PMT 2008] performed without glycolysis (a) Carbohydrates are used as respiratory substrate (a) TCA cycle (b) HMP pathway (b) Organic acids are used as respiratory substrate (c) Both (a) and (b) (d) None of the above (c) The oxidation of the respiratory substrate consumed In which of the following process 36 ATP molecules are 3. more oxygen than the amount of CO2 released produced by per hexose molecule (d) The oxidation of the respiratory substrate consumed (a) Glycolysis (b) Kreb's cycle less oxygen than the amount of CO2 released (c) Direct oxidation pathway (d) None of the above (e) The reaction is anaerobic 4. The substrate for pentose phosphate pathway is [BHU 2012] 3. Which of the following respiratory material may show the (a) Glucose-6-phosphate (b) Glucose-1-phosphate unit value of R.Q. (c) Fructose-6-phosphate (d) Fructose-1-phosphate (a) Stem of wheat (b) Leaf of barley 5. Shikimic acid can be made from (c) Leaf of oat (d) All the above 4. Which of the following respiratory substrates requires the (a) Xylulose (b) Erythrose-4-phosphate highest number of $\,O_2\,$ molecules for its complete oxidation (c) Ribulose (d) None of the above 6. HMP shunt is an alternative to (a) Tripalmitin (b) Triolein (a) Kreb's cycle (b) Aerobic glycolysis (c) Tartaric acid (d) Oleic acid (c) Calvin cycle (d) C₄ pathway 5. Substance whose RQ is less than one is Which of the following statements is / are not true (a) Carbohydrate (b) Protein A. One ATP molecule yields 32 kJ of energy (c) Organic acid (d) All the above 6. When the respiratory substances are more than one then B. Pentose Phosphate Pathway was discovered by Dickens which respiratory substrates are not used [GUJCET 2015] C. When tripalmitin is used as a substrate, the R.Q. is 0.7 (a) Pure Protein (b) Lipid D. Energy released by one molecule of glucose on (c) Carbohydrate (d) (A) and (B) both complete oxidation corresponds to 1292 kJ 7. What is the value of RQ of castor seeds, if the imaginary values of Ganong's respirometer are as follows [Kerala PMT 2006] First rise of saline $= 10 \, ml$ (a) A, B and D only (b) C and D only (ii) Second rise of saline after adding KOH = 30 ml(c) A and D only (d) A, C and D only

(e) Conly

(a) 0.33

(c) 0.85

The energy content in Kcal/g of carbohydrate : protein : 8. triglycerol respectively is approximately in the ratio of

[AMU (Med.) 2010, 12]

- (a) 1:2:2
- (b) 1.1.2
- (c) 2:1:1
- (d) 2:2:1
- The respiratory quotient during cellular respiration would depend on [KCET 2009]
 - (a) The nature of enzymes involved
 - (b) The nature of the substrate
 - (c) The amount of carbon dioxide released
 - (d) The amount of oxygen utilised
- R.Q. in anaerobic respiration is

[JIPMER 1998; Wardha 2005]

(a) 0

(b) 00

(c) 1

- (d) > 1
- The R.Q. of a plant organ depends upon the nature of the substrate which is
 - (a) Reduced
- (b) Oxidized
- (c) Catabolized
- (d) Metabolized
- R.Q. of fatty substances is generally 12.

[RPMT 1999, 2002; KCET 1999; AMU (Med.) 2012]

- (a) Unity
- (b) Less than one (Approx 0.7)
- (c) Greater than one
- (d) Zero
- 13. Which of the following option is correct for the given statements, 'X', 'Y' and 'Z'

Statement 'X' - R.Q. of fat containing palmatic acid is less than one, whereas R.Q. of glucose is 1

Statement 'Y' - Fat containing palmatic acid need less O2 for respiration and glucose need more oxygen for respiration

Statement 'Z' - Fat containing palmatic acid has much less oxygen in its constitution as compared to glucose

[GUJCET 2014]

- (a) Statement 'X', 'Y' and 'Z' are correct. Statement 'Y' and 'Z' are correct explanation for 'X'
- (b) Statement 'X' and 'Y' are correct and statement 'Z' is incorrect statement, 'Y' is correct explanation for 'X'
- (c) Statement 'X' and 'Z' are correct and statement 'Y' is incorrect statement, 'Z' is correct explanation for 'X'
- (d) Statement 'X' and 'Z' are incorrect and statement 'Y' is correct
- In Opuntia, in night the R.Q. will be
 - (a) One
- (b) Less than one
- (c) More than one
- (d) Zero
- 15. In succulents respiratory quotient is always less than one because of
 - (a) Complete oxidation
- (b) Complete reduction
- (c) Incomplete oxidation
- Incomplete reduction
- The R.Q. value of oxalic acid is
 - [Kerala PMT 2009]

- (a) 1.0
- (b) 0.7
- (c) 4 (e) 1.5
- (d) ∞
- In germinating castor seeds, the R.Q. is [BHU 1995, 2003;

CBSE PMT 2002; MHCET 2003; MP PMT 2011]

A mixture containing equal quantity of germinating maize and groundnut seeds are taken. The RQ of this mixture would be

- (a) One
- (b) More than one
- (c) Less than one
- (d) Zero

- 18. R.Q. of malic acid is
- [RPMT 1995]

(a) 0.7

- (c) 1.33
- (d) 4
- The correct relationship of value of Respiratory Quotient is 19. [RPMT 1997]
 - (a) Glucose symbol > Fats symbol > Organic acid
 - (b) Glucose symbol < Fats symbol < Organic acid
 - (c) Fats symbol > Glucose symbol > Organic acid
 - (d) Fats symbol < Glucose symbol < Organic acid
- 20.
 - R.Q. is more than one in case of

[MP PMT 2000]

If the volume of CO2 liberated during respiration is more than the volume of O2 used, the respiratory substance will be

- (b) Fructose
- (c) Glucose
- (d) Organic acid
- R.Q of sprouting potato tubers will be 21.
 - [BVP 2002]

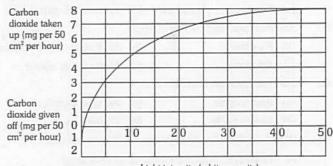

- (c) > 1
- (d) 0
- 22. RQ (respiratory quotient) is defined as
- [NCERT;

DPMT 2003, 04; KCET 2004; BVP 2004; Kerala PMT 2006]

- (a) Volume of CO_2 evolved = volume of O_2 consumed
- Volume of O consumed
- Volume of CO2 evolved
- Volume of CO2 evolved Volume of O2 consumed
- Volume of O2 evolved Volume of CO2 consumed

Factor affecting respiration

The graph shows the relation between light intensity and the giving off and taking up of carbon dioxide by the leaves of a plant. Why is most carbon dioxide given off when the light intensity is zero units

Light intensity (arbitrary units)

[Kerala PMT 2004]

- (a) Because it is just the start of the experiment
- (b) Only respiration is taking place at this intensity of light
- (c) Only photosynthesis is taking place at this intensity of light
- (d) The rate of photosynthesis is equivalent to the rate of respiration
- (e) The rate of photosynthesis is more than the rate of respiration

UNIVERSAL BOOK DEPOT 1960

- 2. The potato growing in hilly areas is bigger in size due to
 - (a) High rate of photosynthesis at high altitude
 - (b) Low rate of respiration at high altitude
 - (c) Due to formation of more fat
 - (d) None of the above
- 3. When an unripe banana is sealed in a polythene bag, it remains green for many days. But if an apple is also sealed in the same bag, the banana ripens and turns yellow within a few days. The reason is that apple [BHU 1994]
 - (a) Removes O₂ released by the banana and thus promotes ripening
 - (b) Produces CO2 which promotes ripening
 - (c) Removes CO2 which inhibits ripening
 - (d) Releases ethylene which promotes ripening
- 4. If the temperature is increased (above 35° C)
 - (a) Rate of decline of respiration will be earlier than decline of photosynthesis
 - (b) Rate of decline of photosynthesis will be earlier than decline of respiration
 - (c) Both decline simultaneously
 - (d) Both do not show any fixed pattern
- CO₂ concentration has which relation with respiration
 - (a) Directly proportional
- (b) Inversely proportional
- (c) Both (a) and (b)
- (d) No relation
- 6. Which statement is wrong
 - (a) Stomatal opening is influenced by many factors and potassium
 - (b) All enzymes are proteins but all proteins are not enzymes
 - (c) All angiosperms are with seeds but all seed plants are not angiosperms
 - (d) Factors which effect the respiration influence the photosynthesis but reverse is not possible
- Which of the following is necessary for respiration in plants
 - (a) Carbon dioxide
- (b) Oxygen
- (c) Chlorophyll
- (d) Light
- 8. The rate of respiration of young maturing seeds is quite high but as water contents decreases during further maturation, respiration
 - (a) Remains high
- (b) Stops completely
- (c) Increases steadily
- (d) Decreases steadily
- In presence of cyanide, azide and carbon monoxide, the rate of respiration
 - (a) Decreases
- (b) Increases
- (c) Remains the same
- (d) None of the above

NCERT Exemplar Questions

- The ultimate electron acceptor of respiration in an aerobic organisms is [NCERT]
 - (a) Cytochrome
- (b) Oxygen
- (c) Hydrogen
- (d) Glucose
- Phosphorylation of glucose during glycolysis is catalysed by [NCERT]
 - (a) Phosphoglucomutase
- (b) Phosphoglucoisomerase
- (c) Hexokinase
- (d) Phosphorylase

- Pyruvic acid, the key product of glycolysis can have many metabolic fates. Under aerobic condition it forms [NCERT]
 - (a) Lactic acid
- (b) CO2+H2O
- (c) Acetyl Co A+ CO2
- (d) Ethanol + CO2
- 4. Electron Transport System (ETS) is located in mitochondrial [NCERT]
 - (a) Outer membrane
- (b) Inter membrane space
- (c) Inner membrane
- (d) Matrix
- Match the following and choose the correct option from those given below

Column A

Column B

- A. Molecular oxygen
- i. α Ketoglutaric acid
- B. Electron acceptor
- i. hydrogen acceptor
- C. Pyruvate dehydrogenase iii.
 - iii. Cytochrome C
- D. Decarboxylation
- iv. acetyl Co A
- Options
 (a) A-ii, B-iii, C-iv, D-i
- (b) A-iii, B-iv, C-ii, D-i
- (c) A-ii, B-i, C-iii, D-iv
- (d) A-iv, B-iii, C-i, D-ii
- Choose the correct statement

[NCERT]

[NCERT]

- (a) Pyruvate is formed in the mitochondrial matrix
- (b) During the conversion of succinyl Co-A to succinic acid a molecule of ATP is synthesized
- (c) Oxygen is vital in respiration for removal of hydrogen
- (d) There is complete breakdown of glucose in fermentation
- Mitochondria are called power houses of the cell. Which of the following observations support this statement [NCERT]
 - (a) Mitochondria systhesise ATP
 - (b) Mitochondria have a double membrane
 - (c) The enzymes of the Krebs cycle and the cytochromes are found in mitochondria
 - (d) Mitochondria are found in almost all plants and animal cells
- 8. The end product of oxidative phosphorylation is [NCERT]
 - (a) NADH
- (b) Oxygen
- (c) ADP
- (d) ATP+ H₂O

Critical Thinking

Objective Questions

- The chemiosmotic coupling hypothesis of oxidative phospohorylation proposes that adenosine triphosphate (ATP) is formed because [CBSE PMT 2008; DUMET 2009]
 - (a) A proton gradient forms across the inner membrane
 - (b) There is a change in the permeability of the inner mitochondrial membrane toward adenosine diphosphate (ADP)
 - (c) High energy bonds are formed in mitochondrial proteins
 - (d) ADP is pumped out of the matrix into the intermembrane space

- How many molecules of ATP and NADPH are require in formation of two molecules of glucose? How many calvin cycles are required [GUJCET 2015]
 - (a) 36 ATP, 24 NADPH, 12 Calvin cycles
 - (b) 18 ATP, 12 NADPH, 6 Calvin cycles
 - (c) 36 ATP, 24 NADPH, 6 Calvin cycles
 - (d) 24 ATP, 36 NADPH, 12 Calvin cycles
- Four respiratory enzymes are given below. Arrange them in increasing order of the carbon number of the substrates on which they act
 - (I) Enolase

(II) Aconitase

(III) Fumerase

(IV) Alcohol dehydrogenase

[EAMCET 2009]

(a) II, IV, III, I

(b) IV, I, II, III

(c) I, IV, III, II

(d) IV, I, III, II

4. Match the compounds given in Column I with the number of carbon atoms present in them which are listed under Column II. Choose the answer which given the correct combination of alphabets of the two columns

	Column-I		Column-II
(A)	Oxaloacetate	(p)	6-C compound
(B)	Phosphoglycrealdehyde	(q)	5-C compound
(C)	Isocitrate	(r)	4-C compound
(D)	α -ketoglutarate	(s)	3-C compound
and f	levolori remailemen si	(t)	2-C compound

[KCET 2009]

				- Control of the Cont
	A	В	C	D
(a)	S	t	q	r .
(a) (b)	r	S	p	q
(c)	r	t	p	q
(d)	q	S	p	t

- 5. In respiration the energy is produced during the process of
 - (a) Glycolysis
- (b) Krebs cycle
- (c) Glycolysis and Kreb's cycle(d) Ornithine cycle
- 6. Hibernating animals have tissues containing mitochondria with a membrane protein that accelerates electron transport while blocking the synthesis of ATP. What is the consequence of this [KCET 2015]
 - (a) Hibernating animals can synthesize fat instead of wasting energy of respiration
 - (b) Energy is saved because glycolysis and the citric acid cycle shuts down
 - (c) Pyruvate is converted to lactic acid by anaerobic fermentation
 - (d) The energy of respiration is converted into heat
- Production of glucose from amino acids, fatty acids and glycerol is called [MP PMT 2009]

Or

Synthesis of glucose from sources other than Carbohydrate is called [WB JEE 2016]

- (a) Glycogenesis
- (b) Gluconeogenesis
- (c) Glycogenolysis
- (d) Glycolysis

- 8. Net yield of aerobic respiration during Krebs' cycle per glucose molecule is [WB JEE 2009]
 - (a) 2 ATP molecules
- (b) 8 ATP molecules
- (c) 36 ATP molecules
- (d) 38 ATP molecules
- 9. Which of the following is non-enzymatic phosphorylation
 - (a) Formation of fructose 1, 6-diphosphate
 - (b) Formation of dihydroxyacetone phosphate
 - (c) Formation of 1, 3-diphosphoglyceraldehyde
 - (d) All the above
- 10. In alcohol fermentation

[CBSE PMT 2003]

- (a) Oxygen is the electron acceptor
- (b) Triose phosphate is the electron donor while acetaldehyde is the electron acceptor
- (c) Triose phosphate is the electron donor while pyruvic acid is the electron acceptor
- (d) There is no electron donor
- The number of glucose molecules required to produce 38 ATP molecules under anaerobic conditions by a yeast cells is

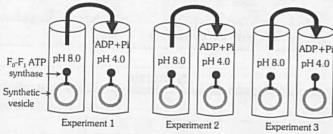

[Kerala PMT 2004; AFMC 2009]

(a) 2

(b) 4

- (c) 19
- (d) 25
- (e) 38
- 12. Harden and Young's ester is formed during glycolysis from
 - (a) Fructose-6-phosphate
- (b) Glucose-6-phosphate
- (c) Glucose
- (d) None of the above
- 13. Select the wrong statement
- [Kerala PMT 2010, 11]
- (a) When tripalmitin is used as a substrate in respiration, the R.Q. is 0.7
- (b) The intermediate compound which links glycolysis with Kreb's cycle is malic acid
- (c) One glucose molecule yields a net gain of 36 ATP molecules during aerobic respiration
- (d) One glucose molecule yields a net gain of 2 ATP molecules during fermentation
- (e) The scheme of glycolysis was given by Embden, Meyerhof and Parnas
- 14. Which among the following is the most appropriate reason for storing green coloured apples at low temperature (Refrigerator)
 - (a) The rate of photosynthesis is reduced
 - (b) Respiration and photosynthesis are completely inhibited
 - (c) The rate of respiration is reduced
 - (d) The rate of photosynthesis and respiration are reduced
- **15.** In the process of respiration in plants 180 gms of sugar plus 192 gms of oxygen produce
 - (a) Large amount of CO2, no water and no energy
 - (b) 132 gms of CO2, 54 gms of water and 337 kcals of energy
 - (c) 264 gms of CO₂, 108 gms of water and 674 kcals of energy
 - (d) 528 gms of CO2, 216 gms of water and 1348 kcals of energy

- When ATP molecule is hydrolysed in ADP, then the quantity of energy released is about
 - (a) 120 cal
- (b) 1, 200 cal
- (c) 12,000 cal
- (d) 1,20,000 cal
- 17. The R.Q. (Respiratory quotient) of $C_{39}H_{72}O_6$ is
 - (a) 2.71
- (b) 1.34
- (c) 0.72
- (d) 3.250
- 18. Experiments 1, 2 and 3 were conducted wherein synthetic vesicles containing F₀ F₁ ATP synthase were prepared and incubated overnight in a tube. Subsequently, the vesicles were transferred to another tube which also contained ADP and Pi (inorganic phosphate)

- A. A proton gradient across the vesicular membrane will be present in both experiments 1 and 2 at the time of transfer
- B. As a consequence of the proton gradient, ATP will be synthesized in both experiments 1 and 2
- C. ATP will be synthesized in experiment 3 because F₀ –F₁ ATP synthase has the inherent property to catalyse the synthesis of ATP from ADP and Pi
- D. ATP will be synthesized in experiment 2 because the proton has to flow out of the vesicles through the F_0 F_1 ATP synthase for ATP synthesis [NCERT]
- (a) A and D
- (b) C and D
- (c) B and C
- (d) A and B
- The time taken from the fixation of CO₂ to the formation of one glucose molecules is about ______ seconds

[MHCET 2015]

(a) 20

- (b) 40
- (c) 60

- (d) 90
- 20. In an experiment demonstrating the evolution of oxygen in Hydrilla, sodium bicarbonate is added to water in the experimental set-up. What would happen if all other conditions are favourable [KCET 2009]
 - (a) Amount of oxygen evolved decreases as carbon dioxide in water is absorbed by sodium bicarbonate
 - (b) Amount of oxygen evolved increases as the availability of carbon dioxide increases
 - (c) Amount of oxygen evolved decreases as the availability of carbon dioxide increases
 - (d) Amount of oxygen evolved increases as carbon dioxide in water is absorbed by sodium bicarbonate

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below :

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- Assertion : In alcoholic fermentation, the hexose molecule is converted into glucose and fructose.
 - Reason : Alcoholic fermentation is anaerobic respiration brought about by enzyme zymase.

[AIIMS 1996]

- Assertion : Glycolysis occurs in cytoplasm.
 - Reason : Enzymes for glycolysis are found in cytoplasm. It is common in aerobic/anaerobic respiration.[AIIMS 2002]
- Assertion : In electron transport chain, there is a gain of energy at each step.
 - Reason : At each step of ETC, there are electron carriers.
- Assertion : The inner membrane of mitochondria contains systems involving electron transport.
 - Reason : The mitochondrial matrix contains enzymes of Kreb's cycle.
- **5.** Assertion : Both hexokinase and glucokinase require divalent cation Mg^{++} or Mn^{++} .
 - Reason : The divalent cations act as catalysts.
- Assertion : One way of indicating the ATP yield from oxidative phosphorylation is the P/O ratio.
 - Reason : The cell stores 40% of the chemical energy.
- Assertion : Cytochromes are a group of copper containing electron transferring proteins.
 - Reason : The terminal cytochrome reacts with oxygen.
- Assertion : Cytochrome oxidase enzyme contains copper.
 - Reason : Cyanide combines with copper of cytochrome oxidase and prevents oxygen combining with it [AIIMS 2010]

9. Assertion : Substrate level phosphorylation is present

in glycolysis.

Reason : Substrate level phosphorylation causes

synthesis of ATP.

10. Assertion : Under aerobic conditions, pyruvate gives

rise to lactate.

Reason : Under anaerobic condition, pyruvate gives

rise to acetyl CoA.

11. Assertion: Terminal oxidation occurs both in aerobic

and anaerobic conditions.

Reason: Terminal oxidation occurs at terminal step

of respiration.

12. Assertion: During the hydrolysis of typical chemical

bonds, about 3000 calories per mole are

liberated.

Reason : ATP also yields about 3000 calories per

mole after the release of any one of the two

terminal phosphates.

13. Assertion : Fructose-1, 6 diphosphate is converted into

glyceraldehyde-3-phosphate and dihydroxy

-acetone-3-phosphate.

Reason : Conversion of fructose-1,6 diphosphate into

3-phosphoglyceraldehyde and dihydroxyace

-tone-3-phosphate is facilitated by the

enzyme aldolase.

[AIIMS 2010]

Answers and Solutions

Anaerobic respiration

 (d) Pasteur's effect: The increase of rate of glycolysis in absence of O₂ is due to the non-availability of those enzymes which are easily available in presence of O₂.

- 6. (c) $C_6H_{12}O_6 \longrightarrow 2C_2H_5OH + 2CO_2 + 21$ Kcal
- 8. (a) Cyanide is deadly poison which inhibit the activity of cytochrome oxidase enzyme of electron transport chain. As in case of aerobic respiration there is no electron transport chain involved, therefore, anaerobic respiration is cyanide resistant pathway.
- 11. (a) In absence of O_2 , fermentation or anaerobic respiration occurs.
- (b) During anaerobic respiration in yeast glucose formed CO₂, C₂H₅OH and energy.
- (d) Continuous addition of sugar in 'fed batch' fermentation is done to purify enzymes.
- 19. (b) Anaerobic respiration first studied by Kostychev (1902).
- **20.** (b) Number of ATP mol. evolved in one complete cycle of anaerobic respiration is 2.
- 21. (b) In yeast fermentation, the enzymatic reactions are as follows

$$(1) \ \ C_{12}H_{22}O_{11} + H_2O \xrightarrow{\quad \text{Invertase} \\ \quad \text{in yeast} } C_6H_{12}O_6 + C_6H_{12}O_6 \\ \text{Fructose}$$

(2)
$$C_6H_{12}O_6 \xrightarrow{\text{Zymase}} 2C_2H_5OH$$

 $+2CO_2 + 21$ kcal energy.

Introduction and types of respiration

- (a) Oxysome acts as the unit of phosphorylation in respiration by the formation of ATP from ADP occur on oxysome. These are present on cristae of mitochondria.
- (d) Respiration rate high at growing regions like floral and vegetative bud, germinating seedlings, young leaves stem and root apices.
- (c) Two molecules of glycine form a molecule of serine, CO₂ and NH₃ in mitochondria.
- 14. (d) In submerged hydrophytes (plants which remain completely dipped in the water) CO₂ enters through epidermis as both carbonates and bicarbonates.
- 17. (a) ADP $\xrightarrow{\text{hydrolysis}}$ AMP + Pi + 7.3kcal.
- (b) Chemiosmotic hypothesis of ATP synthesis or oxidative phosphorylation given by Petel mitchell's.
- 19. (b) In aerobic respiration glycolysis is linked with, kreb's cycle through acetyl Co-A because pyruvic acid (end product of glycolysis) first converted into acetyl Co-A. Acetyl Co-A enter in the kreb's cycle. The formation of acetyl Co-A is involved with some cofactors like. Mg⁺⁺ ions thiamine pyrophosphate, (Vit-B₁) NAD⁺, Co-A and lipoic acid.
- **21.** (d) ATP was discovered by Lohmann (1926) and ATP cycle by Lipmann (1941) who won Nobel prize in 1953.
- 23. (b) Cellular respiration is an enzyme controlled process of biological oxidation of food materials in a living cell. Using molecular O₂, producing CO₂ and H₂O and releasing energy in small step and storing it in biologically useful forms generally ATP. It occurs in mitochondria.
- 24. (b) Kreb's cycle takes place in the matrix and ATP formation takes place on oxysome of cristae in mitochondria.

- 25. (d) Pyruvic acid is the end product of glycolysis. This pyruvic acid forms acetyl CoA. Acetyle CoA is a initial compound of Kreb's cycle.
- 28. (c) Respiration is a biological enzymatic reaction while combustion is a chemical process.
- 30. (a) ATP is a higher nucleotide resembling to ribonucleotide having adenine base, ribose sugar and three phosphate groups.
- 31. (c) Because it takes place in living beings (biological matter).
- 33. (b) Because kreb's cycle occurs in matrix of mitochondria.
- **34.** (a) According to Lundegarth amount of anion absorbed by plant cells rather than to the absorption of cations of salts so it is also called anion respiration.
- 37. (d) Aerobic respiration yields 10NADH₂, 2FADH₂, 2GTP and 2ATP resulting into 10NADH₂ = 10×3 = 30 ATP 2FADH₂ = 2×2 = 4 ATP 2GTP = 2×1 = 2 ATP 2ATP = 2×1 = 2 ATP

38 ATP

- (c) Primary respiratory substrate is carbohydrate and secondary respiratory substrate is fat.
- (d) As 300 ppm is normal concentration of CO₂, hence there is no effect on plant.
- (c) Cellular respiration is an enzyme controlled process of biological oxidation of food materials in living cell.
- 54. (a) The energy present in one gram of fats is 9.8kcal or 41kJ, which is maximum as compared to another substrate.
- 57. (a) ATP $\xrightarrow{hydrolysis}$ ADP + Pi + 7.3 kcal
- 58. (b) Because it is an energy liberating process.

Glycolysis

- (b) Two molecules of ATP are consumed in glycolysis during phosphorylation of glucose to fructose 1, 6diphosphate.
- 6. (a) Pyruvic acid is end product of glycolysis.
- 9. (b) Decarboxylation is the removal of carbon from a compound by using carbon to make CO₂. During kreb's cycle the acetyl group pass round the cycle and the two carbon atoms are lost in the form of carbon dioxide in two decarboxylation reactions.
- (b) Glucose 6-phosphate → 3-phosphoglyceraldehyde → 3-phosphoglyceric acid → phosphoenol pyruvate → pyruvic acid.
- **13.** (c) Breakdown of glucose into 2 molecules of pyruvic acid is known as glycolysis.
- 17. (b) The net reaction of glycolysis would be $C_6H_{12}O_6 + 2ADP + 2Pi + 2NAD + \xrightarrow{Glucose}$ $2C_3H_4O_3 + 2NADH(+H^+) + 2ATP + 2H_2O$ Pyruvate $C_6H_{12}O_6 + 8ADP + 8Pi \longrightarrow 2C_3H_4O_3 + 8ATP + 2H_2O$ Pyruvate

- 18. (b) Glycolysis takes place in the cytoplasm and does not use Oxygen. In anaerobic respiration only glycolysis is found, in which there is no need of mitochondria.
- (b) Glucose is converted into glucose 6-phosphate is first step of glycolysis.
- **20.** (a) Glycolysis occurs in all the living cells because this is common process in both aerobic and anaerobic respiration.
- 21. (b) Six carbon glucose molecule forms two molecules of three carbon pyruvic acid. $C_6H_{12}O_6 \rightarrow 2C_3H_4O_3 + 4H$
- 22. (a) Glycolysis was discovered by Embden, Meyerhof and Parnas.
- **24.** (a) Two molecules of pyruvic acid are formed by one molecule of glucose by glycolysis.
- **26.** (a) $C_6H_{12}O_6$ is glucose and $C_3H_4O_3$ is pyruvic acid.
- (a) EMP pathway is most common which was discovered by Embden, Meyerhof and Parnas (1930).
- **29.** (b) Fructose 6-phosphate +ATP Phosphofructokinase,Mg²⁺ Fructose 1, 6-diphosphate +ADP. Glucose is converted into glucose 6-phosphate by ATP in the presence of enzyme hexokinase.
- **32.** (b) Complete oxidation of one molecule of glucose produce 10 molecules of NADH₂.

Kreb's cycle and ETS

- (c) Malate is dehydrogenated or oxidised through the agency of malate dehydrogenase to produce oxaloacetate.
- 8. (c) Amino acid like aspartate and glutamate on deamination from organic acids like OAA and α. Ketoglutaric acid respectively which enter into kreb's cycle.
- 14. (b) If O₂ is not available pyruvic acid undergo anaerobic respiration/fermentation, but under aerobic condition the pyruvic acid enter into mitochondria and converted to Acetyl Co-A. Acetyl CoA functions as substrate entrant for Krebs cycle. So, a connecting link between glycolysis and Krebs cycle.
- **21.** (b) 1 molecule of glucose yields 56kcal/2ATP in anaerobic respiration and 686000 calories (686 kcal)/total of 38 ATP in aerobic respiration.
- **22.** (a) Under aerobic condition pyruvate is converted into acetyl co-enzyme-A and CO_2 is released. Acetyl co-enzyme-A combines with oxaloacetic acid and form citric acid.
- 26. (c) In eukaryotes the entire site of reaction of kreb's cycle occur in the matrix of mitochondria.
- **28.** (d) Largest amount of ATP is produced during aerobic respiration (38 ATP). It includes 8 ATP in glycolysis and 30 ATP in kreb's cycle.
- 30. (a) Dehydrogenation process converts succinate into 4-carbon fumarate with the aid of an enzyme, succinate dehydrogenase and liberates a pair of hydrogen atoms. The latter pass to FAD+ forming FADH₂.

- **38.** (c) In aerobic respiration, CO_2 is produced at 3 step:
 - (i) During acetyl Co-A formation.
 - (ii) During formation of a-ketoglutaric acid in kreb's cycle.
 - (iii) During succinic acid formation in kreb's cycle.
- 39. (b) During sixth step succinate is oxidised into fumarate by the enzyme succinate dehydrogenase and two hydrogens are transferred to FAD to form FADH₂.
- 46. (b) Reductive amination is the method of amino-acid synthesis in plants. In this method, α-keto glutaric acid reacts with ammonia (NH₃) and forms the amino acid called glutamic acid. The enzyme glutamate dehydrogenase enhances the reaction.
- 57. (b) Cytochrome a₃ is terminal cytochrome of ETC. It has Fe⁺⁺⁺ and Cu⁺⁺ both. With Fe⁺⁺⁺, it picks up electrons and through Cu⁺ it passes electrons to oxygen.
- 61. (c) Kreb's cycle is an important step of aerobic respiration in which largest molecules of ATP are formed.
- **62.** (b) These are arranged in order of their increasing redox potential and electron flow through the chain in step wise manner from the more electronegative compound to the more electropositive O_2 . On the basis of redox potential cytochrome acceptor order is cyt b c a a_3 .
- 64. (c) Fe-S complex is responsible for passing electrons (also protons) from mitochondria NADH/NADPH to ubiquinone.
- (c) In aerobic conditions pyruvic acid formed in glycolysis enters in the matrix of mitochondria.
- **66.** (d) Succinyl $CoA \xrightarrow{H_2 O}$ succinic acid.
- 67. (a) ATP is not electron transferring molecule. It is a energy storing molecule. So it is called as currency of energy.
- **68.** (d) Cytochromes contain Fe with porphyrin pigment. The electrons pass through the cytochromes reducing their Fe^{+3} into Fe^{+2} ($Fe^{+3} + e^- \rightarrow Fe^{+2}$).
- 69. (a) Cytochromes occur in cristae of mitochondria because all cytochromes involved in electron transport system.
- 70. (b) The oxygen is the terminal acceptor of electrons which forms a water molecule in presence of protons in ETS

$$\left(\frac{1}{2}O_2 + 2e^- \rightarrow O^{-2}, 2H^+ + O^{-2} \rightarrow H_2O\right)$$

Pentose phosphate pathway

- (c) The complete oxidation of one glucose molecule forms 12NADPH which are equivalent to 36 ATP molecules.
- (b) PPP provides erthyrose— 4 phosphate which is required for the synthesis of shikimic acid. The latter is a precursor of aromatic ring compounds.
- (b) HMP is an alternate method of aerobic respiration and occurs in cytoplasm.
- 9. (b) PEP was described by Warburg (1935) and Dickens (1938).

R.Q.

- 1. (a) $C_6H_{12}O_6 + 6O_2 \longrightarrow 6CO_2 + 6H_2O$ R.Q. = $\frac{\text{Vol. of }CO_2}{\text{Vol of }O_2} = \frac{6}{6} = 1$
- (d) In the above green organs the value of R.Q. is always one because in them for respiration hexose molecule is needed, in which CO₂ and O₂ molecules are equal.
- 5. (b) Since amount of CO_2 released is less than absorbed O_2 , therefore the value of $RQ\left(\frac{CO_2}{O_2}\right)$ is less than unity.
- 7. (b) $\frac{Vol. \text{ of } CO_2}{\text{Vol. of } O_2} = \frac{V_2 \text{ cc}}{V_1 \text{ cc} + V_2 \text{ cc}}$ $\Rightarrow R.Q. = \frac{30 \text{ cc}}{10 \text{ cc} + 30 \text{ cc}} = 0.75.$
- 10. (b) During anaerobic respiration, due to the absence of O_2 the value of R.Q. is infinite (or more than one). $C_6H_{12}O_6 \longrightarrow 2CO_2 + 2C_2H_5OH$ $R.Q. = \frac{2}{2} = \text{(infinite)}.$
- **11.** (b) Respiratory quotient depends upon the type of substrate participating in respiration.
- 13. (c) Carbohydrate $C_6H_{12}O_6+6O_2\rightarrow 6CO_2+6H_2O+\text{Energy}$ $RQ=\frac{6CO_2}{6O_2}=1$

Fats: The value of RQ is less than 1. This would mean that there is much less oxygen in the constitution of fat as compared to that in carbohydrates. Thus, they need more O_2 for respiration.

As an example, the equation for respiration of Tripalmitin is as under

 $2(C_{51}H_{98}O_6) + 145O_2 \rightarrow 102CO_2 + 98H_2O$ Energy

$$RQ = \frac{102CO_2}{145O_2} = 0.7.$$

14. (d) In some succulent or fleshy plants e.g., Opuntia, carbohydrates are incompletely oxidized to organic acids in dark without the evolution of CO_2

$$2C_6H_{12}O_6 + 3O_2 \longrightarrow 3C_4H_6O_5 + 3H_2O$$
 glucose malic acid

R.Q. =
$$\frac{CO_2}{O_2} = \frac{0}{0} = 0$$
 (less than one)

- 17. (c) In germinating castor seeds, respiratory substrate is fat. Maize contains carbohydrate and groundnut seed contains fatty acid. R.Q. of these substances are respectively less than 1. Thus total R.Q. will be less than one.
- **18.** (c) $C_4H_6O_5 + 3O_2 \longrightarrow 4CO_2 + 3H_2O_3$ R.Q. = $\frac{4}{3}$ = 1.3 (more than one).

UNIVERSAL BOOK DEPOT 1960

728 Respiration in Plants

Factor affecting respiration

- (d) In apple, gaseous hormone ethylene is produced which helps in ripening of banana to convert it yellow.
- (b) If the amount of CO₂ in the air more than usual rate of respiration is decreased.
- (b) Oxygen is essential for aerobic respiration it is the ultimate acceptor of electrons in electron transport system (E.T.S).
- 8. (d) Water is essential for accelerating enzyme activity. In conditions of water stress therefore the respiration decreases that's why in dry fruits and seeds in respiratory enzyme least active, show minimum respiration.
- (a) Cyanides, azides and carbon monoxide work as enzyme inhibitors, thus the rate of respiration decreases.

Critical Thinking Questions

- 14. (c) At low temperature in green apple, the galactose sugar consumption reduces in respiration due to which they remain as such fresh for long time.
- 15. (c) Reaction of respiration is

$$C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O + 674$$
 kcal

In this reaction considering molecular weight of each element, we get

 $C_6H_{12}O_6 = 6 \text{ times } 12 + 12 \text{ times } 1 + 6 \text{ times } 16 = 180 \text{ gm}$

$$O_2 = 6 \text{ times } 32 = 192 \text{ gm}$$

Now we consider products of this reaction i.e. $6CO_2$ and $6H_2O$

$$6CO_2 = 6(12 + 32) = 264 gm$$

$$6H_2O = 6(2 + 16) = 108 gm$$

17. (c)
$$2C_{39}H_{72}O_6 + 108O_2 \rightarrow 78CO_2 + 72H_2O$$

$$\therefore \text{ R.Q.} = \frac{\text{Volume of } CO_2 \text{ evolved}}{\text{Volume of } O_2 \text{ used up}} \frac{78}{108} = .072$$

Assertion and Reason

- (e) Alcoholic fermentation is the respiration in absence of O₂. In this process, hexose molecule is changed to ethyl alcohol and CO₂. In presence of zymase enzyme. In this less amount of energy is released as compared to aerobic respiration.
- (a) Glycolyis occurs in cytoplasm as all necessary enzymes are found in it. This process is common in aerobic/anaerobic respiration. In this process, one glucose molecule is converted into 2 molecules of pyruvic acid.
- 3. (e) The passage of electrons from one enzyme or cytochrome to the next is a downhill journey with a loss of energy at each step. At each step the electron carriers include flavins, iron sulphur complexes, quinones and cytochromes.

- 4. (b) The inner membranes of mitochondria contain all systems involving electron transport. The mitochondrial matrix contains all the soluble enzymes of the citric acid or Kreb's cycle and those involved in the oxidation of fatty acids.
- (c) Both kinases require a divalent cation (Mg²⁺ or Mn²⁺), which first combines with ATP to form the true substrate, MgATP²⁻ or MnATP²⁻
- 6. (b) One way of indicating the ATP yield from oxidative phosphorylation is the P/O ratio, which is expressed as the moles of inorganic phosphate used per oxygen atom consumed. The cell stores 40% of the chemical energy liberated by the combustion of glucose in the form of ATP. The rest of the energy is dissipated as heat or used for other cell functions.
- 7. (e) The cytochromes are a group of iron containing electron-transferring proteins of aerobic cells that act sequentially to transfer electrons from flavoprotein to molecular oxygen. The terminal cytochrome of the electron transport chain, which can react with oxygen, is called cytochrome oxidase.
- 8. (b) The final stage of respiratory chain involves cytochrome oxidase which contains copper. This stage can be specifically inhibited by cyanide or carbon monoxide. Cyanide combines with the copper and prevents oxygen combining with it.
- 9. (b) One of the two phosphates of diphosphoglycerate is linked by high energy bond. It can synthesize ATP and form 3-phosphoglycerate. The enzyme is phosphoglycerate kinase. The direct synthesis of ATP from metabolites is called substrate level phosphorylation.
 - During formation of phosphoenol pyruvate the phosphate radical pick up energy. It helps in the production of ATP by substrate level phosphorylation.
- 10. (d) Under aerobic conditions, the products are pyruvate and coenzyme NADH. Pyruvate directly enters the mitochondrial matrix and is converted into acetyl-CoA. Under anaerobic conditions, pyruvate is used as a hydrogen acceptor and converted into lactate. In anaerobic conditions, pyruvate remains in the cytosol.
- 11. (e) Terminal oxidation is the name of oxidation found in aerobic respiration that occurs towards the end of catabolic process and involves the passage of both electrons and protons of reduced coenzymes to oxygen.
- 12. (c) During the hydrolysis of typical chemical bonds, about 3000 calories per mole are liberated. The release of any one of the two terminal phosphates of ATP yields about 7300 calories per mole, instead of the 3000 calories from common chemical bonds. The standard free energy of hydrolysis of ATP to ADP and phosphate is 7.30 K cal at pH 7.0 and temperature 37°C in the presence of excess Mg²⁺.
- 13. (b) Fructose 1, 6-diphosphate in the presence of enzyme aldolase is converted into a glyceraldehyde-3phosphate and a dihydroxy acetone-3-phosphate molecules.

Fructose 1, 6-diphosphate \Longrightarrow 3PGA+DiHAP.

T Self Evaluation Test

- 1. Enzymes found attached to inner membrane mitochondria instead of matrix is/are [AFMC 2006]
 - (a) Succinic dehydrogenase (b) Cytochrome oxidase
 - (c) Both (a) and (b)
- (d) Malic dehydrogenose
- Anaerobic respiration is also known as
 - (a) Intramolecular respiration
 - (b) Intermolecular respiration
 - (c) Extramolecular respiration
 - (d) Molecular respiration
- 3. The process by which ATP is produced in the inner membrane of a mitochondrion. The electron transport system transfers protons from the inner compartment of the outer, as the protons flow back to the inner compartment, the energy of their movement is used to add phosphate to ADP, forming ATP [AIIMS 2009]
 - (a) Chemiosmosis
- (b) Phosphorylation
- (c) Glycolysis
- (d) Fermentation
- 4. Which of the following processes make direct use of oxygen
 - [Kerala PMT 2006; CPMT 2010]
 - (a) Glycolysis
- (b) Fermentation
- (c) Electron transport
- (d) Kreb's citric acid cycle
- (e) Hydrolysis
- What is active glucose 5.
 - (a) FAD-glucose
- (b) NAD-glucose
- (c) Phosphoglucose
- (d) Glycerophosphate
- 6. High fatty acids are breaking by
- [RPMT 1999]

- (a) β -oxidation
- (b) α-oxidation
- (c) Glycolysis
- (d) All of these
- 7. How many ATP will be produced during the production of 1 molecule of acetyl CoA from 1 molecule of pyruvic acid
 - [MP PMT 1996, 2006]

- (a) 3 ATP
- (b) 5 ATP
- (c) 8 ATP
- (d) 38 ATP
- 8. Fruit keep better in refrigeration, this is due to
 - (a) Non-availability of O2
- (b) Absence of moisture
- (c) Accumulation of O₂
- (d) Inactivation of respiration
- Vant Hoff's law states that
- [KCET 1994]
- (a) The respiration rate increases two or three times for every rise of 5° C
- (b) The respiration rate decreases two or three times for every rise of 10° C
- (c) The respiration rate does not increase or decrease with change in temperature
- (d) The respiration rate increases two or three times for every rise of 10° C
- A characteristic feature of ripening of some fruits (like banana) is a sudden increase in respiration which is known as
 - (a) Climacteric
- (b) Anthesis
- (c) Climatic
- (d) Photorespiration
- R.Q. is highest when respiratory substance is
 - (a) Fat
- (b) Malic acid
- (c) Glucose
- (d) Protein

- An indispensable role in energy metabolism is played by (a) Sodium
 - (b) Phosphorus
 - (c) Calcium
- (d) Potassium
- Fermentation is conducted by

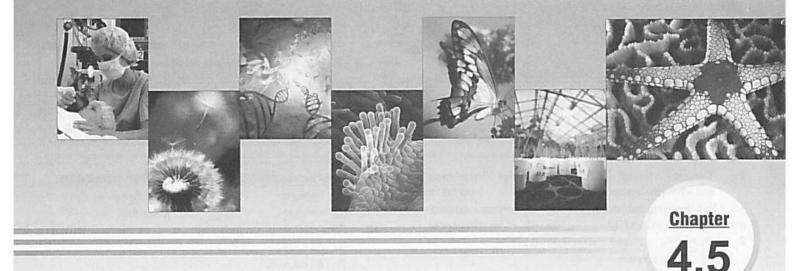

[NCERT]

- (a) All fungi
- (b) All bacteria
- (c) Some fungi and some bacteria
- (d) All micro-organisms

Answers and Solutions

1	C	2	a	3	a	4	C	5	C
6	a	7	a	8	d	9	d	10	a
11		12	b	13	c	- Albert	1000	A BASE	

- All the enzymes of Kreb's cycle, fatty acid synthesis and amino acid synthesis are found in matrix but succinic dehydrogenese and cytochrome oxidase are present on inner membrane of mitochondria.
- 3. (a) Chemiosmosis is the diffusion of ions across a selectively-permeable membrane. More specifically, it relates to the generation of ATP by the movement of hydrogen ions across a membrane during cellular
- (a) Fats hydrolyse in fatty acids and glycerol. Fatty acids after β -oxidation forms to acetyl CoA and glycerol forms to triose phosphates.
- (a) During acetyl CoA formation by pyruvic acid, only one NADH2 is formed by which 3 molecules of ATP are formed.
- 8. (d) Respiratory rate is low in refrigeration.
- 9. (d) The respiration rate increases two or three times for every rise of 10°C called or Vant Hoffs law which is between 2 to 2.5.
- (a) Some fruits (e.g., banana and apple) show high rates of respiration during their ripening. This rise in respiratory rate is called climacteric.
- (b) Because malic acid is an organic acid, which after oxidation produces more CO2, due to which the value of R.Q. is four.
- 12. (b) Because phosphorus produces energy coins ATP.
- (c) Fermentation is anaerobic breakdown of carbohydrates into alcohol, organic acids with the help of microorganisms (fungi, bacteria).

Growth can be defined as a vital process which brings about irreversible permanent change in any plant or its part with respect to its size, form, weight and volume.

Regions of growth: In unicellular plants there is overall growth and not confined to any specific region but in multicellular plants growth is restricted to specific regions having meristematic cells. On the basis of their position in the plant body (higher plants) meristems are divided into three main categories.

- (1) Apical meristems: These meristems are found at shoot and root apex. As a result of activity of these meristems plant increases in length. In angiosperms and gymnosperms there is a group of meristematic cells but in bryophytes and pteridophytes there is a single tetrahedral cell found at the shoot apex.
- (2) **Intercalary meristems**: These meristems are found above the nodes. As a result of the activity of these meristems increase in length takes place. e.g., Bambusa.
- (3) Lateral meristems.: These meristems are made up of cells which divide in radial direction only. They form laterally placed new cells towards the centre and periphery. Cork cambium (phellogen) and vascular cambium are the examples of lateral meristems. Increase in girth of shoots and roots take place because of the activity of this cambium.

Phases of growth

- (1) **Cell division (Formative phase) :** Growth is based on mitotic cell division.
- (2) **Cell enlargement**: Cell division is followed by cell enlargement. The cell increases in size due to vacuolation (by absorption of water). The cell enlargement has been explained in two different ways. According to the first view, the turgor of the cell is responsible for cell enlargement. The other view considers that as a result of growth of the cell wall the volume of the cell increases.

(3) **Cell maturation (Differentiation)**: Cell differentiation followed by cell division and cell enlargement leads to the development of specialized mature tissue cell. *e.g.*, xylem tracheids and trachea, sieve tubes and companion cells.

Growth curve: The rate of growth varies in different species and different organs. The young leaf sheath of banana grows for a time at the rate of almost three inches per hour. Growth begins slowly, then enters a period of rapid enlargement, following which it gradually decreases till no further enlargement occurs. The mathematical curve which represents this variation in growth rate is some what flattened S-shaped curve or sigmoid curve. Time in which growth takes place has been called grand period of growth. This term was coined by Sachs. The analysis of growth curve shows that it can be differentiated into three phases:

- (1) **Lag phase**: The rate of growth is very slow in lag phase. More time is needed for little growth in this phase.
- (2) Log phase (Exponential phase): The growth rate becomes maximum and more rapid. Physiological activities of cells are at their maximum. The log phase is also referred to as grand period of growth.

(3) Final steady state

Log phase Lag phase

Fig: 4.5-1 A typical S-shaped grand period of growth curve

(Stationary phase) or Adult phase: When the nutrients become limiting, growth slows down, so physiological activities of cells also slows down. This phase indicates maturity of growth system. The rate of growth can be measured by an increase in size or area of an organ of plant like leaf, flower, fruit etc. The rate of growth is called efficiency index.

UNIVERSAL BOOK DEPOT 1960

In many plants another phase is also evident in their growth curve. This is called linear phase or phase of maximum growth rate. Sachs called it as grand phase.

Measurement of growth

The following methods are designed to measure growth in length:

- Direct method: Measurement is done between two marked points by a scale at regular intervals.
 - (2) Horizontal microscope (Travelling microscope)
- (3) Auxanometer: Several kinds of auxanometers have been devised to measure the growth in length of a plant. Two of them are:
 - (i) Arch auxanometer
 - (ii) Pfeffer's auxanometer (Automatic auxanometer)
- (4) Bose's crescograph: The crescograph invented by Sir Jagdish Chandra Bose is a more delicate instrument and gives magnification upto 10,000 times. The rate of growth of root can be measured by the use of a root auxanometer.

Factors influencing rate of growth: Growth is affected by the factors which affect the activity of protoplasm. It is affected by a large number of factors both environmental and physiological. Physiological factors such as absorption of water, minerals, photosynthesis, respiration etc, and environmental factors including climatic and edaphic both. The effect on these factors on one region of plant are also transmitted to other region of the plant.

Since growth is a resultant of many metabolic processes, it is affected by many external and internal factors, which are as follows:

External factors

- Light: Light affects variously e.g., light intensity, quality and periodicity.
- (i) Intensity of light: In general, light retards growth in plants. High light intensities induce dwarfing of the plant. Plants at hill tops are short whereas those of a valley are quite tall. Very weak light induces the rate of overall growth and also photosynthesis. Development of chlorophyll is dependent on light and in its absence etiolin compounds are formed which gives yellow colour to the plant. The phenomenon is called etiolation. Similarly high light intensity affects indirectly and increases the rate of water loss and reduces the rate of water growth.
- (ii) Quality of light: The different colours (different wavelengths) affect the growth of plant. In blue-violet colour light internodal growth is pronounced while green colour light reduces the expansion of leaves as compared to complete spectrum of visible light. The red colour light favours elongation but they resemble etiolated plants. Infrared and ultraviolet are detrimental to growth. However, ultraviolet rays are necessary for the development of anthocyanin pigments in the flowers. Blue and violet colour increases size of lamina of leaf.

- (iii) Duration of light: There is remarkable effect on duration of light on the growth of vegetative as well as reproductive structures. The induction and suppression of flowering are dependent on duration. The phenomenon is termed photoperiodism.
- (2) **Temperature :** Temperature has pronounced effect on the growth of plant. The temperature cardinals for growth vary according to temperature zones. The minimum, optimum and maximum temperatures are usually $5^{\circ}C$ (arctic), $20-30^{\circ}C$ (temperate) and $35-40^{\circ}C$ (tropical). The optimum temperature needed for the growth of a plant is much dependent on the stages of development.
- (3) Water: As water is an essential constituent of the living cell, a deficiency of water causes stunted growth.
- (4) **Oxygen**: In poorly aerated soil there is low concentration of oxygen and a high concentration of CO_2 . Under such conditions plants usually show stunted growth. Normal growth of most plants occurs only when abundant oxygen is present since O_2 is important for respiration. It has been reported that oxygen plays some important role during G_1 stage of cell division.
- (5) **Mineral salt :** Absence of essential mineral salts results in abnormal growth. For example, the absence of nitrogen prevents protein-synthesis, while the absence of iron prevents chlorophyll formation and thus leads to pale and sickly growth of plants, known as chlorotic condition.
- (6) **Pollutants**: Several pollutants such as automobile exhaust, peroxyacetyl nitrate (PAN), pesticides etc have detrimental effect on plant growth. Citrus and Gladiolus are very sensitive to fluorides. Poor growth of tobacco is observed in regions where ozone concentration is high. White pine cannot survive under high O_3 concentration. Cotton plants are similarly very sensitive to ethylene.
- (7) Carbon dioxide: CO₂ is essential for photosynthesis and hence nutrition. Due to change in photosynthetic rate, with the increase or decrease in CO₂ concentration, the plant growth is also affected.

Internal factors

- (1) **Nutrition**: It provides raw material for growth and differentiation as well as source of energy. C/N (Carbohydrate/Nitrogen) ratio determines the type of growth. High C/N ratio stimulates wall thickening. Less protoplasm is formed. Low C/N ratio favours more protoplasm producing thin walled soft cells. According to law of mass growth, the initial rate of growth depends upon the size of germinating structure (seed, tubes, rhizome, bulb, etc.)
- (2) Growth regulators: These are manufactured by living protoplasm and are important internal growth regulators which are essential for growth and development. These growth regulators include several phytohormones and some synthetic substances.

Differentiation, Dedifferentiation and Redifferentiation

The cells derived from root apical and shoot-apical meristems and cambium differentiate and mature to perform specific functions. This act leading to maturation is termed as differentiation. During differentiation, cells undergo few to major structural changes both in their cell walls and protoplasm. For example, to form a tracheary element, the cells would lose their protoplasm. They also develops a very strong, elastic, lignocellulosic secondary cell walls, to carry water to long distances even under extreme tension.

Plants show another interesting phenomenon. The living differentiated cells, that by now have lost the capacity to divide can regain the capacity of division under certain conditions. This phenomenon is termed as **dedifferentiation**. For example, formation of meristems — interfascicular cambium and cork cambium from fully differentiated parenchyma cells. While doing so, such meristems/tissues are able to divide and produce cells that once again lose the capacity to divide but mature to perform specific functions, i.e., get **redifferentiated**.

Growth hormones and Growth regulators

The term hormone was first used by Starling (1906). He called it stimulatory substance. The growth and development in plants is controlled by a special class of chemical substances called hormones. They are needed in small quantities at very low concentrations as compared to enzyme. They are rarely effective at the site of their synthesis.

Thus, growth hormones are also called phytohormones term given by Thimann (1948), it can be defined as 'the organic substances which are synthesized in minute quantities in one part of the plant body and transported to another part where they influence specific physiological processes'. A group of plant hormones including auxins, gibberellins, cytokinins, ethylene and abscisic acid are presently known to regulate growth.

Auxins: Auxins (Gk. auxein = to grow) are weakly acidic growth hormones having an unsaturated ring structure and capable of promoting cell elongation, especially of shoots (more pronounced in decapitated shoots and shoot segments) at a concentration of less than 100 ppm which is inhibitory to the roots. Among the growth regulators, auxins were the first to be discovered.

Discovery: Julius Von Sachs was the first to indicate the presence of organ forming substances in plants. The existence of first plant growth hormone came from the work of Darwin and Darwin (1881). Darwin described the effects of light and gravity in his book, "Power of movements in plants". Darwin and his son found that bending movement of coleoptile of Canary grass (*Phalasis canariensis*) was due to exposure of tip to unilateral light. Boysen-Jensen (1910; 1913) found that the tip produces a chemical which was later named auxin. Paal (1914, 1919) removed coleoptile tip and replaced it asymmetrically to find a curvature. Auxin was first collected by Went (1928) from coleoptile tip of *Avena*. Went also developed *Avena* curvature test for bioassay of auxin.

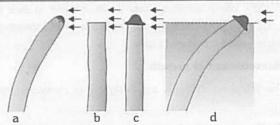

Fig: 4.5-2 Experiment used to demonstrate that tip of the coleoptile is the source of auxin. Arrows indicate direction of light

Types of auxins: There are two major categories of auxins natural auxins and synthetic auxins.

(1) **Natural auxins**: These are naturally occurring auxins in plants and therefore, regarded as phytohormones. Indole 3-acetic acid (IAA) is the best known and universal auxin. It is found in all plants and fungi.

The first naturally occurring auxin was isolated by Kogl and Haagen-Smith (1931) from human urine. It was identified as auxin-a (auxenotriolic acid, $C_{18}H_{32}O_5$). Later, in 1934 Kogl, Haagen-Smith and Erxleben obtained another auxin, called auxin-b

CH₂COOH

Indole acetic acid (IAA)

(auxenolonic acid, $C_{18}H_{30}O_4$) from corn germ oil (extracted from germinating corn seeds), and heteroauxin from human urine. Heteroauxin ($C_{10}H_9O_2N$) also known as indole-3-acetic acid (IAA), is the best known natural auxin. Besides IAA, indole-3-acetaldehyde, indole-3-pyruvic acid, indole ethanol, 4-chloro-idole acetic acid (4-chloro-IAA) etc., are some other natural auxins.

Natural auxins are synthesized (Young) in physiologically active parts of plants such as shoot apices, leaf primordia and developing seeds, buds (apex), embryos, from amino acid tryptophan. In root apices, they are synthesized in relatively very small amount. Auxins show polar movement. It is basipetal (from apex to base) in stem but acropetal (from root tip towards shoot) in the root. Auxins move slowly by diffusion from cell to cell and not through the vascular tissues. Auxins help in the elongation of both roots and shoots. However, the optimum concentration for the two is quite different.

It is 10 ppm for stem and 0.0001 ppm for the root. Higher concentration of auxins show inhibitory effect on growth.

(2) Synthetic auxins: These are synthetic compounds which cause various physiological responses common to IAA. Some of the important synthetic auxins are 2, 4-D (2, 4-dichlorophenoxy acetic acid) is a weedicide, 2, 4, 5-T (2, 4, 5-trichlorophenoxy acetic acid), IBA (indole 3-butyric acid), NAA (naphthalene acetic acid, PAA (Phenyl acetic acid), IPA (Indole 3-propionic acid). IBA is both natural and synthetic auxin. Certain compounds inhibit action of auxin and compete with auxins for active sites and are called antiauxins. e.g., PCIB (p-chlorophenoxy isobutyric acid), TIBA (2, 3, 5-tri iodobenzoic acid). TIBA is used in picking cotton balls.

Bioassay of Auxins : Testing of biological activity (growth) of a substance (auxin) by employing living material is called bioassay.

(1) Avena coleoptile curvature test: Avena curvature test carried out by F.W. Went (1928) demonstrated the effect of auxins on plant growth by performing some experiments with the oat (Avena sativa) coleoptile.

- (2) **Split pea stem curvature test:** This test was also discovered by Went, 1934.
- (3) Root growth inhibition test (Cress root inhibition test) Functions of auxins: Auxins control several kinds of plant growth processes. These are as follows:
- (1) Cell elongation: Auxins promote elongations and growth of stems and roots and enlargement of many fruits by stimulating elongation of cells in all directions.

The auxins cause cell enlargement by solubilisation of carbohydrates, loosening of microfibrils, synthesis of more wall materials, increased membrane permeability and respiration.

(2) Apical dominance: In many plants, the apical bud grows and the lower axillary buds are suppressed. Removal of apical bud results in the growth of lower buds. The auxin (IAA) of the terminal bud inhibits the growth of lateral buds. This phenomenon is known as apical dominance.

This property of auxins has found use in agriculture. Sprouting of lateral buds (eyes) of the potato tuber is checked by applying synthetic auxin (NAA).

Moving on a grass lawn facilitates better maintenance primarily owing to removal of apical dominance.

(3) Control of abscission layer: Auxin inhibits abscission of leaves and fruits. Abscission layer is produced when the auxin content falls below a minimum.

Premature drop of fruits such as apple, pear and citrus can be prevented to a great extent by spraying the trees with a dilute solution of IAA, NAA or some other auxin.

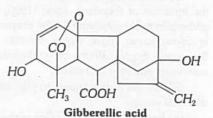

- (4) **Weed control**: By the spray of 2, 4-D, broad-leaved weeds can be destroyed but 2, 4-D does not affect mature monocotyledonous plants.
- (5) **Root differentiation:** Many new plants are usually propagated by stem cutting e.g., Rose, Bougainvillea. If we dip the lower cut end of a cutting in dilute solution of auxins (specially IBA gives very good results) very soon large number of roots are developed on the cut ends due to which these cuttings develop into successful plants.
- (6) Parthenocarpy: Parthenocarpy can be induced by application of IAA in a paste form to the stigma of a flower or by spraying the flowers with a dilute solution of IAA. Banana, oranges and grapes are now-a-days grown parthenocarpically on commercial scale. Auxins are applied in lanolin paste on stigma for inducing parthenocarpy.
- (7) Control of lodging: In some plants when the crop is ripe and there is heavy rain accompanied by strong winds, the plants bend as a result of which the ear (inflorescence) gets submerged in water and decays. If a dilute solution of any auxin is sprayed upon young plants the possibility of bending of plants is reduced as the stem becomes stronger by the application of auxins.
- (8) Flowering: In pineapple, NAA promotes flowering. In lettuce, auxins help in delaying the flowering. In cotton plants, the use of auxins increases the cotton seeds production.
- (9) Differentiation of vascular tissues: Auxins induce the differentiation of xylem and phloem in intact plants and also in callus produced in vitro during tissue culture experiments.
- (10) **Sex expression**: The spray of auxins increases the number of female flowers in cucurbits. In maize, application of NAA during the period of inflorescence differentiation can induce formation of hermaphrodite or female flowers in a male inflorescence.

Thus auxins cause femaleness in plants.

- (11) **Healing**: Healing of injury is effected through auxin induced division in the cells around the injured area. The chemical was formerly named traumatic acid or traumatin.
- (12) **Nodule formation :** In legumes, IAA is known to stimulate nodule formation.
- (13) Respiration: According to French and Beevers (1953) the auxin may increase the rate of respiration indirectly through increased supply of ADP by rapidly utilizing the ATP in the expanding cells.

Gibberellins: Gibberellins are weakly acidic hormones

having gibbane ring structure which cause cell elongation of intact plants in general and increased internodal length of genetically dwarfed plants (i.e., corn, pea) in particular.

Discovery

Gibberellins were first isolated from the fungus Gibberella fujikuroi (Fusarium moniliforme) the causal organism of Bakanae disease or foolish seedling disease of rice plants in Japan by Kurosawa in 1926.

In 1939, Yabuta and Sumiki and coworkers working in Tokyo isolated an active substance from the fungus and called it Gibberellin A. This gibberellin preparation was probably a mixture of several gibberellins. The first gibberellin to be obtained was Gibberellin A-3. Cross et al. (1961) explained the detailed structure of gibberellic acid. Now 60 gibberellins have been identified from different groups of plants.

Many of them occur naturally in plants. Gibberella fujikuroi has as many as 15 gibberellins. All the different types of gibberellins, known so far, have gibbane skeleton and are acidic in nature. Anti-gibberellins like malic hydrazide, phosphon D, Alar and chorocholine cheoride (CCC) or cycocel are also called antiretardants (stimulates flowering and inhibits the growth of nodes). Commercial production of GA is still carried out by culturing this fungus in large vats.

Bioassay of gibberellin : Gibberellin bioassay is performed through dwarf maize/pea test and cereal endosperm test.

Functions of gibberellin

- (1) Stem elongation: The gibberellins induce elongation of the internodes. The elongation of stem results due to rapid cell division and cell elongation induced by gibberellins.
- (2) Leaf expansion: In many plants leaves become broader and elongated when treated with gibberellic acid. This leads to increase in photosynthetic area which finally increases the height of the plant. Interestingly, gibberellins show no effect on roots.
- (3) Reversal of dwarfism: One of the most striking effects of gibberellins is the elongation of genetic dwarf (mutant) varieties of plants like corn and pea. It is believed that dwarfism in the mutant variety of plant is due to blocking of the capacity for normal gibberellin production (deficiency of gibberellin). When gibberellin is applied to single gene dwarf mutants e.g., Pisum sativam, Vicia faba and Phaseolus multiflorus, they grow to their normal heights. It is further interesting to note that application of gibberellins to normal plants fail to show any remarkable effects.

(4) **Bolting**: Gibberellins induce stem elongation in 'rosette plants' e.g., cabbage, henbane, etc. Such plants show retarded internodal growth and profuse leaf development. In these plants just prior to the reproductive phase, the internodes elongate enormously causing a marked increase in stem height. This is called bolting.

Bolting needs long days or cold nights. It has been further noticed that if cabbage head is kept under warm nights, it remains vegetative. The exogenous application of gibberellins induced bolting in first year itself in plants like cabbage (normally bolting occurs next year due to effect of endogenous gibberellins).

(5) **Flowering**: Gibberellins also play an important role in the initiation of flowering. Lang (1960) demonstrated that added gibberellin could substitute for the proper environmental conditions in *Hyoscyamus niger* which requires long day treatment for flowering. Such effects of gibberellin are common among vernalised and long day plants.

Gibberellin is also known to play essential role in germination of cereal seeds.

- (6) **Enzyme formation :** One of the most dramatic effects of GA is its induction of hydrolytic enzymes in the aleurone layer of endosperm of germinating barley seeds and cereal grains. GA stimulates the production of digestive enzymes like proteases, α -amylases, lipases which help to mobilise stored nutrients. GA treatment stimulates a substantial synthesis of new mRNA. Thus GA acts to uncover or depress specific genes, which then cause the synthesis of these enzymes. It is assumed that GA acts on the DNA of the nucleus.
- (7) **Breaking of dormancy**: Gibberellins overcome the natural dormancy of buds, tubers, seeds, etc. and allow them to grow. Sprouting of potato in cold storage occur due to GA. In this function gibberellins act antagonistically to abscisic acid (ABA).
- (8) Parthenocarpy: Gibberellins have been considered to be more effective than auxins for inducing parthenocarpy in fruits like apple, tomato and pear. GA application has also resulted in the production of large fruits and bunch length in seedless grapes.
- (9) Sex expression: Gibberellins control sex expression in certain plants. In general, gibberellin promote the formation of male flowers either in place of female flowers in monoecious plants such as cucurbits or in genetically female plants like Cannabis, Cucumis.
- (10) **Substitution for vernalization**: Vernalization is the low temperature requirement of certain plant (i.e., biennials) to induce flowering. The low temperature requirement of biennials for flowering can be replaced by gibberellins.
- (11) **Malt yield**: There is increased malt production when gibberellins are provided to germinating barley grains (due to greater production of α -amylase).
- (12) Delayed ripening: Ripening of citrus fruits can be delayed with the help of gibberellins. It is useful in safe and prolonged storage of fruits.
- (13) **Seed germination**: Gibberellins induce germination of positively photo-blastic seeds of lettuce and tobacco in complete darkness.

Cytokinins (Phytokinins): Cytokinins are plant growth hormones which are basic in nature, either aminopurine or phenyl urea derivatives that promote cell division (cytokinesis) either alone or in conjugation with auxin.

Discovery: The first cytokinin was discovered by Miller, Skoog and Strong (1955) during callus tissue culture of *Nicotiana* tobaccum (tobacco).

It was synthetic product formed by autoclaving Herring sperm (fish sperm) DNA. This synthetic product was identified as 6-furfuryl amino-purine and named as kinetin. He found that normal cell division induced by adding yeast extract.

Various terms such as kinetenoid (Burstran, 1961), phytokinin (Dendolph et al. 1963) phytocytomine (Pilet 1965) have been used for kinetin like substances but the term cytokinin proposed by Letham (1963) has been widely accepted. Letham et al. (1964) discovered first natural, cytokinin in unripe maize grain (Zea mays). It was named as zeatin (6 hydroxy 3 methyl trans 2-butenyl amino purine).

About 18 cytokinins have been discovered, e.g., dihydrozeatin, IPA (Isopentenyl adenine), benzyl adenine. The most widely occurring cytokinin in plant is IPA. It has been isolated from *Pseudomonas tumefaciens*. Many are found as constituents of tRNAs. Cytokinins are synthesized in roots as well as endosperm of seeds. Coconut milk and Apple fruit extract are rich in cytokinins. Cytokinins in coconut milk are called coconut milk factor.

Kinetin (6 furfuryl amino purine) is a derivative of the nitrogen base adenine. Cytokinins are produced in actively growing tissues such as embryos, developing fruits and roots.

Cytokinin is transported to different parts of the plant through xylem elements.

NH-CH₂

Kinetin (6-furfuryl aminopurine)

According to Osborne and Black (1964), the movement of cytokinin is polar and basipetal.

Bioassay of cytokinins: Bioassay is done through retention of chlorophyll by leaf discs, gains of weight of a tissue in culture, excised radish cotyledon expansion, root inhibition test etc.

Functions of cytokinins

- (1) **Cell division:** Cytokinins are essential for cytokinesis and thus promote cell division. In presence of auxin, cytokinins stimulate cell division even in non-meristematic tissues. In tissue cultures, cell division of callus (undifferentiated mass of parenchyma tissue) is enhanced when both auxin and cytokinin are present. But no response occurs with auxin or cytokinin alone.
- (2) Cell enlargement and Differentiation: Under some conditions cytokinins enhance the expansion of leaf cells in leaf discs and cotyledons. These cells considered to be mature and under normal conditions do not expand. Cytokinins play a vital role in morphogenesis and differentiation in plants. It is now known that kinetin-auxin interaction control the morphogenetic differentiation of shoot and root meristems.
- (3) **Delay in senescence**: Cytokinin delay the senescence (ageing) of leaves and other organs by controlling protein synthesis and mobilization of resources (Disappearance of chlorophyll). It is called Richmond Lang effect. It was reported by Richmond and Lang (1957) while working on detached leaves of *Xanthium*.
- (4) Counteraction of apical dominance: Auxins and cytokinins act antagonistically in the control of apical dominance. Auxins are responsible for stimulating growth of apical bud. On the other hand, cytokinins promote the growth of lateral buds. Thus exogenous application of cytokinin has been found to counteract the usual dominance of apical buds.
- (5) **Breaking of dormancy**: Cytokinins break seeds dormancy of various types and thus help in their germination. They also induce germination of positively photoplastic seed like lettuce and tobacco even in darkness.

UNIVERSAL BOOK DEPOT 1960

- (6) Accumulation and Translocation of solutes: Cytokinins induce accumulation of salts inside the cells. They also help solute translocation in phloem.
- (7) Sex expression: Cytokinins promote formation of female flowers in some plants.
- (8) Enzyme activity: Cytokinins stimulate the activity of enzymes especially those concerned with photosynthesis.
- (9) Parthenocarpy: Development of parthenocarpic fruits through cytokinin treatment has been reported by Crane (1965).
- (10) **Pomalin**: A combination of cytokinin (6-benzladenine) and gibberellin (GA_4 , GA_7) called pomalin is particularly effective in increasing apple size.
- (11) **Initiation of interfasicular cambium :** Cytokinins induce the formation of interfasicular cambium in plants e.g., *Pinus radiata*.
- (12) Nucleic acid metabolism: Guttman (1957) found a quick increase in the amount of RNA in the nuclei of onion root after kinetin treatment.
- (13) Protein synthesis: Osborne (1962) demonstrated the increased rate of protein synthesis on kinetin treatment.
- (14) **Short day plants**: Cytokinins promote flowering in some short-day plants like *Lemna* and *Wolffia*.

Ethylene: Ethylene is a gaseous hormone which stimulates transverse growth but retards the longitudinal one.

Discovery: The effect of ethylene had been known since long. Kerosene lamps and hay have been used by fruit merchants to hasten colour development (ripening) in fruits. These effects are due to ethylene. Neljubow (1901) observed that ethylene gas alters the tropic responses of roots. Denny (1924) reported that ethylene induces ripening of fruits. Crocker *et al.* (1935) identified ethylene as gaseous plant hormone.

Ethylene is produced in plants from the amino acid methionine. It is synthesized in almost all plant parts-roots, leaves, flowers, fruits, seeds. It is more synthesized in nodal regions. Maximum synthesis of ethylene occurs during climacteric ripening of fruits. High concentration of auxin induce ethylene formation. When a fruit ripens, its respiration rate gradually decreases, but when it is reversed by a sharp increase called climacteric. Some of the inhibitory effects earlier attributed to auxin are known to be caused by ethylene.

The commercial product for providing ethylene is ethaphon (2-chloroethyl phosphoric acid). Ethaphon is a liquid from which ethylene gas is released, hence this substance is used for artificial ripening of fruits.

Bioassay of ethylene: It is done on the principle of triple response which includes three characteristic effects of ethylene on etiolated seedlings of pea-viz.

- Swelling of nodes.
- Inhibition of elongation of internodes of stem.
- Induction of horizontal growth of stem against gravity.

Functions of ethylene

(1) **Fruit growth and Ripening:** Ethylene promotes fruit growth and its ripening. The hormone is used in the artificial ripening of climacteric fruits (e.g., Apple, Banana, Mango).

Suitable combination of gases in atmosphere for fruit ripening is 80% ethylene (C_2H_4) and 20% CO_2 .

- (2) Transverse growth: Ethylene inhibits longitudinal growth but stimulates transverse growth so that stem looks swollen.
- (3) Epinasty (leaf bending): Epinasty represents more growth on upper surface of leaf than on lower surface. Epinasty is said to be controlled by ethylene in many plants.
- (4) **Abscission**: Ethylene stimulates formation of abscission zone in leaves, flowers and fruits.
- (5) Apical dominance: Ethylene inhibits the growth of lateral buds and thus cause apical dominance (in pea). It is believed that auxin might be functioning partly through synthesis of ethylene in causing apical dominance.
- (6) **Root initiation :** In low concentration, ethylene stimulates root initiation and growth of lateral roots and root hair.
- (7) **Flowering**: Ethylene stimulates flowering in pineapple and related plants though in other cases, the hormone causes fading of flowers. Fading flowers of *Vanda* are known to release ethylene. Sleep disease (inrolling of petals in blossomed flowers) in due to ethylene.
- (8) **Sex expression**: Ethylene application increases the number of female flowers and fruits in cucumber plants.
- (9) Dormancy: It breaks dormancy of different plant organs but not of lateral buds.

Abscisic acid (ABA): Abscisic acid is a mildly acidic growth hormone, which functions as a general growth inhibitor by counteracting other hormones (auxin, gibberellins, cytokinins) or reactions mediated by them.

Discovery: The hormone was first isolated by Addicott et al. (1963) from cotton balls. They named it as abscisin II. Simultaneously, Wareing and Cornforth isolated a substance that can induce bud dormancy. They named the substance as dormin. Later, both these substances were found to be the same and were named as abscisic acid. It is produced in many parts of the plants but more abundantly inside the chloroplasts of green cells. The synthesis of abscisic acid is stimulated by drought, water logging and other adverse environmental conditions. Therefore, it is also called stress hormone. The hormone is formed from mevalonic acid or xanthophylls. Chemically it is dextro-rotatory cis sesquiterpene. The hormone is transported to all parts of the plant through diffusion as well as through conductive channels.

In some plant tissues (especially in young shoots) occur a related compound called xanthoxine.

Whether xanthoxine is an intermediate of the ABA-biosynthesis or whether it is an independent product remains unknown. The structure indicates that both ABA and xanthoxine are terpene derivatives.

Bioassay of abscisic acid

(1) Rice seedling growth inhibition test: Mohanty, Anjaneyulu and Sridhar (1979) used rice growth inhibition method to measure ABA like activity. The length of second leaf sheath after six days of growth is measured.

(2) Inhibition of α -amylase synthesis in barley endosperm test: ABA inhibits the synthesis of α -amylase in the aleurone layers which is triggered by gibberellins. Goldschmidt and Monselise (1968) developed the bioassay method to estimate ABA activity by determining the extent of inhibition of α -amylase synthesis induced by treating barley seed endosperm with GA.

Functions of abscisic acid

- (1) Control: It keeps growth under check by counteracting the effect of growth promoting hormones, i.e., auxins, cytokinins and gibberellins. As growth is primarily controlled by gibberellins, abscisic acid is popularly called antigibberellic hormone. It will inhibit seed germination, growth of excised embryos, growth of Duckweed and other plants.
- (2) Dormancy: Abscisic acid acts as growth inhibitor and induces dormancy of buds towards the approach of winter. Dormancy of seeds is mainly caused by abscisic acid. Because of its action in inducing dormancy abscisic acid (ABA) is also called dormin. The buds as well as seeds sprout only when abscisic acid is overcome by gibberellins.
- (3) **Abscission**: ABA promotes the abscission of leaves, flowers and fruits in plants.
- (4) **Senescence**: Abscisic acid stimulates senescence of leaves by causing destruction of chlorophyll (an effect opposite to that of cytokinins) and inhibition of protein and RNA synthesis. The effect, however, can be reversed by application of cytokinins in *Lemna*.
- (5) Antitranspirant: Abscisic acid can be used as antitranspirant. Application of minute quantity of ABA to leaves reduces transpiration to a great extent through partial closure of stomata. It thus conserves water and reduces the requirement of irrigation.
- (6) **Hardiness**: Abscisic acid promotes cold hardiness and inhibits growth of pathogens.
- (7) **Flowering**: ABA delays flowering in long day plants. However, in some short day plants (e.g., strawberry, black current) it promotes flowering.
- (8) **Rooting**: Abscisic acid can be used to promote rooting in many stem cuttings.

Wound hormone or Traumatic acid or Necrohormone: Haberlandt (1913) reported that injured plants cells release a chemical substance (wound hormone), which stimulate the adjacent cells to divide rapidly in order to heal up the wound. English et al. (1939) finally isolated and crystallized this wound hormone and named it as Traumatic acid. Although traumatic acid has been found to be very active in inducing meristematic activity in uninjured green bean pods, but it is not effective in most of the plant tissues including tobacco pith tissues.

Morphactins: Morphactins are synthetic growth regulators which act in variety of ways on the natural regulation mechanisms of plants. The important ones are phenoxyalkancarboxylic acid (synthetic auxin), substituted benzoic acids, Malic acid hydrazide, Fluorene-9 carboxylic acids and their derivatives, Chloroflurenol, Chloroflurun, Flurenol, Methylbenzilate, Dichloroflurenol, etc. Morphactins have fundamental action on morphogenesis of plants and this characteristic designation (morphactins) is derived from morphologically active substances.

The actions of these substances are systematic and after their uptake they are transported and distributed not polarly (as seen by IAA) but basi- and acropetally. Generally these are growth inhibitors. These contain 'fluorene ring' in their structure.

Functions

- (1) **Seed germination**: In general, morphactins inhibit seeds germination particularly the emergence of the radicle from the seed shell. This property can be counteracted with GA₃ and almost completely by cytokinins. The germination of fern spores is also delayed by morphactins.
- (2) **Growth seedling:** Morphactins inhibit the growth of seedling affecting the shoot and often also root. With this property they show a similarity with cytokinin. The inhibitory effect of seedling shoot growth can be partly counteracted with GA_3 but not the inhibition of root growth.
- (3) **Stem elongation**: They have inhibitory effect on the stem elongation. Increased concentration produces dwarfing in the plants.
- (4) **Polarity of cell division**: Denffer and others (1969) observed in the dividing cells of the root tips of *Allium* that treatment of morphactin (CFI) results in random orientation of the mitotic spindle and plane of cell division, *i.e.*, they exercise depolarisation during cell division.

Jasmonic acid (Jasmonates): According to Parthier (1991), jasmonic acid and its methyl esters are ubiquitous in plants. They have hormone properties, help regulating plant growth, development and they seem to participate in leaf senescence and in the defense mechanism against fungi.

Just like ABA jasmonates inhibit a premature germination

of the oil-containing seeds of Brassica and Linum. After germination they induce the synthesis of the seed storage proteins Napin and Cruciferin as well as that of several more elaiosome-associated proteins.

Calines (Formative hormones): Certain other natural growth hormones in plants called as calines or formative hormone which are through to be essential for the effect of auxin an root, stem and leaf growth they are:

- (1) Rhizocaline or Root forming hormone: It is produced by the leaves and translocated in a polar manner down the stem.
- (2) Caulocaline or Stem forming hormone: It is produced by the roots and is transported upward in the stem.
- (3) Phyllocaline or Self forming hormone: It is produced probably by the cotyledons. It stimulates mesophyll development in the leaves and is synthesized only in the presence of light.

Physiology of flowering plant

Flowering in a plant occurs at a particular time of the year and controlled by many morphological and environmental conditions. Two important controlling factors are photoperiod or light period, i.e., photoperiodism, low temperature i.e., vernalization.

(1) Photoperiodism (Light period): The effects of photoperiods or daily duration of light periods (and dark periods) on the growth and development of plants, especially flowering is called photoperiodism.

UNIVERSAL BOOK DEPOT 1960

The role of photoperiodism in the control of flowering was demonstrated for the first time by W.W Garner and H.A. Allard (1920). They observed that Maryland mammoth variety of tobacco could be made to flower in summer by reducing the light hours with artificial darkening. It could be made to remain vegetative in winter by providing extra light. On the basis of length of photoperiod requirements of plants, the plants have been classified into following categories.

- (i) **Short day plants (SDP)**: These plants initiate flowering when the day length (Photoperiod) become shorter than a certain critical period. Most of winter flowering plants belong to this category e.g., cocklebur (Xanthium), Chrysanthemum, sugarcane, tobacco (Mutant Maryland mammoth), soybean, strawberry, Dahlia etc.
- (ii) Long day plants (LDP): These plants begin flowering when the day length exceeds a critical length. This length too differs from species to species. The long day plants fail to flower, if the day length is shorter than the critical period. e.g., spinach (Spinacea oleracea), henbane (Hyoscymus niger), radish, sugarbeet, wheat, lattuce, poppy, larkspur, maize etc.
- (iii) Day neutral plants: These plants can flower in all possible photoperiods. The day neutral plants can blossom throughout the year. e.g., cucumber, cotton, sunflower, tomato, some varieties of pea, etc.

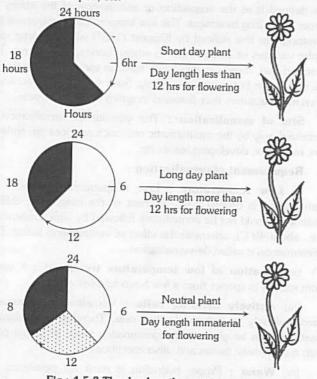

Fig: 4.5-3 The day-length requirements for flowering in three catagories of plants

- (iv) Intermediate plants: These plants flower only under day lengths within a certain range usually between 12-16 hours of light but fail to flower under either longer or shorter photoperiods. e.g., Mikania scandens, Eupatorium hyssopifolium and Phaseolous polystacous.
- (a) **Amphiphotoperiodic plants**: Such plants remain vegetative on intermediate days length and flower only on shorter or longer day lengths. *e.g.*, *Media elegans*.

- (b) **Short long day plants**: These plants require short photoperiods for initiation of flowering and long photoperiods for blossoming. e.g., *Triticum vulgare*, *Secale cereale*.
- (c) Long short day plants: These plants require long photoperiods for initiation of flowering and short photoperiods for blossoming. e.g., Bryophyllum, Cestrum.

Critical period: Critical photoperiod is that continuous duration of light, which must not be exceeded in short day plants and should always be exceeded in long days plant in order to bring them to flower. There is no relation with the total day length. Thus, the real distinction between a SDP and LDP is whether flowering is induced by photoperiods shorter or longer than the critical period. The critical day length for *Xanthium* (a short day plant) is 5 – 6 hours and that for *Hyoscymus niger* (a long day plant) is about 11 hours, yet the former is SDP as it flowers in photoperiods shorter than its critical value, whereas the latter is LDP requiring photoperiods longer than its critical value. Both *Xanthium* and *Hyoscymus niger* flower with 14 hours of light per day. Thus, day length in which a plant flowers is no indication of its response class in the absence of further information.

Skotoperiodism (Dark period): When photoperiodism was discovered, the duration of the light period was thought to be critical for flowering. Subsequently, it was found that when the long night period was interrupted by a brief exposure to light, the short day plants, failed to flower. Thus, for flowering, these plants require a long night or critical dark period rather than a short day length. Similarly, long day plants respond to nights shorter than the critical dark period. Curiously, they do not need an uninterrupted dark period. Therefore, a short day plant is also called long night plant and a long day plant as a short night plant.

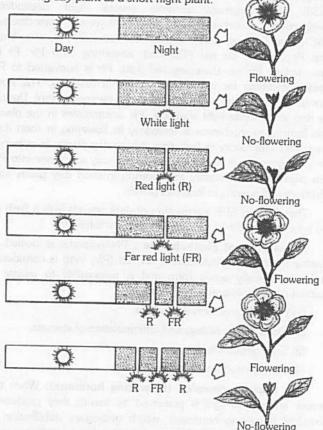

Fig: 4.5-4 Effect of night (Dark) interruption on flowering in a short-day plant

In the night interruption experiments, when the short day plants were exposed to a flash of light before achieving a critical dark period, flowering was prevented. It is called light break reaction.

Mechanism of photoperiodism

Photoreceptor: The chemical which perceives the photoperiodic stimulus in leaves is phytochrome. The wavelengths of light are absorbed by the leaves. This becomes evident by the fact that defoliated (leaves removed) plant does not flower. Presence of even a single leaf is sufficient to receive required amount of photoperiod. Partially mature leaves are more sensitive to light while very young or mature leaves are much less sensitive to photoperiodic induction.

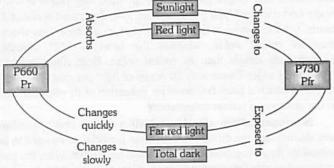

Fig: 4.5-5 The phytochrome concept

Garner and Allard's early work led to the discovery, isolation and much of the characterization of the pigment responsible for absorbing light involved in photoperiodic phenomenon of plants. Borthwick, Hendricks and their colleagues later termed this pigment phytochrome. Pigment was isolated by Butter et al. (1959). This pigment controls several light dependent developmental processes in plants besides flowering, Phytochrome exist in two interconvertible forms. The red (660nm), absorbing form Pr and the far red (730 nm), absorbing form Pfr. Pr is converted to Pfr on absorbing red light. Pfr is converted to Pr rapidly absorbing far red light or slowly in darkness. The slow conversion to red absorbing form is under thermal control. During the day when white light available, Pfr accumulates in the plant. This form of phytochrome is inhibitory to flowering in short day plants and stimulatory to flowering in long day plants. In evening, Pfr undergoes thermal and spontaneous decay to change into Pr. This pigment is stimulatory to flowering in short day plants and inhibitory to flowering in long day plants.

Therefore, in SDP interruption of dark periods with a flash of red light converts *Pr* into *Pfr* and flowering is inhibited.

Importance of phytochrome: Phytochrome is located in plasmamembrane. Phytochrome far red (*Pfr*) form is considered to be biologically active form and is responsible to initiate a number of physiological process such as.

- (1) Elongation of stem and leaves.
- (2) Plastids morphology and differentiation of stomata.
- (3) Seed germination.
- (4) Photoperiodism and transpiration.

The florigen complex (Flowering hormone): When the proper amount of light is perceived by leaves, they produce a chemical (flowering hormone), which undergoes stabilisation in dark. Later on, this chemical passes to shoot apex and causes its differentiation into flowering shoot.

Chailakhyan (1936) a Russian investigator on photoperiodism, proposed that it be called 'florigen'. According to him (1958) the "Florigen complex", the true flowering hormone includes two groups of substances formed in leaves:

Gibberellins: Which are necessary for formation and growth of stem.

Anthesins: Substances which are necessary for flower formation.

Photomorphogenesis: When plants are grown in continuous darkness they become etiolated i.e., such plants are longer, weaker, having yellowish half opened leaves, while light grown plants do not show such conditions. When etiolated plants are kept in light they gradually develop green colour and become normal. The effect of light in reversing etiolation involves two kinds of action; one at the biochemical level for the synthesis of the chlorophyll and secondly at the level of morphogenesis light acts to promote expansion of the leaves and inhibits elongation of the internodes. This phenomenon is called photomorphogenesis and is independent of the direction of light.

The action spectrum of photomorphogenesis reveals that plants are most sensitive to red light, but blue light is ineffective.

(2) Vernalization: Russian agronomist Lysenko coined the term vernalization (1929-30). According to him vernalization may be defined as the method of inducing early flowering in plants by pretreatment of their seeds at low temperatures. Chourad (1960) has defined it as the acquisition or acceleration of the ability to flower by chilling treatment. The low temperature requirement for flowering was first noticed by Klipport (1857) while working with winter varieties of cereals such as wheat, barley, oat and rye. He observed that, these varieties when sown in spring failed to flower the same year but grow vegetatively. Such winter varieties, when sown in the autumn, they flowered in spring of the same year.

Site of vernalization : The stimulus of vernalization is perceived only by the meristematic cells such as shoot tip, embryo tips, root apex, developing leaves etc.

Requirement of vernalization:

- (i) **Low temperature**: Low temperature required for vernalization is usually 0-4°C is most of the cases. The chilling treatment should not be immediately followed by high temperature (i.e., about 40°C), otherwise the effect of vernalization is lost. This phenomenon is called de-vernalization.
- (ii) Duration of low temperature treatment: It varies from species to species from a few hours to a few days.
- (iii) **Actively dividing cells**: Vernalization stimulus is perceived only by actively dividing cells. Therefore, vernalization treatment can be given to the germinating seeds or whole plant with meristematic tissues and other conditions.
- (iv) Water: Proper hydration is must for perceiving the stimulus of vernalization.
- (v) Oxygen: Aerobic respiration is also a requirement for vernalization. The stimulus has been named as vernalin (reported by Mechlers).

Process of vernalization: Usually vernalization treatment is given to the germinating seeds. The seeds are moistened sufficiently to allow their germination. They are then exposed to a temperature of 0-4°C for a few weeks and sown to the fields. Lysenko developed the process of vernalization. It is completed in two stages.

- (i) Thermostage: Germinating seeds are treated with 0-5°C in presence of oxygen and slight moisture. The seed dormancy is broken.
- (ii) Photostage: This stage is very essential to initiate the reproductive phase. After vernalization plants must be subjected to a correct photoperiod in order that they may produce flowers.

Importance of vernalization

- (i) Vernalization is believed to overcome some inhibitor and induce synthesis of growth hormones like gibberellins.
 - (ii) It reduces the vegetative period of plant.
 - (iii) It prepares the plant for flowering.
 - (iv) It increases yield, resistance to cold and diseases.
 - (v) Vernalization can remove kernel wrinkles in wheat.
- (vi) Vernalization is beneficial in reducing the period between germination and flowering. Thus more than one crop can be obtained during a year.

Senescence and Death

Plant and their parts develop continuously from germination until death. The production of flowers, fruits and seeds in annuals and biennials leads to senescence. The latter part of the developmental process, which leads from maturity to the ultimate complete loss of organization and function is termed senescence. Several workers equate ageing and senescence as same process. Ageing is a sum total of changes in the total plant or its constituents while senescence represents degenerative and irreversible changes in a plant. The study of plant senescence is called phytogerontology.

Types of senescence : Plant senescence is of four typeswhole plant senescence, shoot senescence, sequential senescence and simultaneous senescence. The last three are also called organ senescence.

- (1) Whole plant senescence: It is found in monocarpic plants which flower and fruit only once in their life cycle. The plants may be annual (e.g., rice, wheat, gram, mustard etc.), biennials (e.g., cabbage, henbane) or perennials (e.g., certain bamboos). The plant dies soon after ripening of seeds.
- (2) **Shoot senescence**: This type of senescence is found in certain perennial plants which possess underground perennating structures like rhizomes, bulbs, corm etc. The above ground part of the shoot dies each year after flowering and fruiting, but the underground part (stem and root) survives and puts out new shoots again next year. e.g., banana, gladiolus, ginger etc.
- (3) **Sequential senescence**: This is found in many perennial plants in which the tips of main shoot and branches remain in a meristematic state and continue to produce new buds and leaves. The older leaves and lateral organs like branches show senescence and die. Sequential senescence is apparent in evergreen plants e.g., Eucalyptus, Pinus, Mango.
- (4) **Simultaneous or synchronous senescence**: It is found in temperate deciduous trees such as elm and maple. These plants shed all their leaves in autumn and develop new leaves in spring. Because of this shedding of leaves, autumn season is also called fall. e.g., Dalbergia, Elm, Mulberry, Poplar.

Theories of senescence

- (1) Wear and tear: According to this theory, senescence occurs due to loss of activity and cells undergo wear and tear due to disintegration of organelles.
- (2) Toxicity: It is viewed that senescence takes place due to accumulation of toxic and deleterious substances in all.
- (3) Loss of metabolites: It is assumed that senescence leads to gradual depletion of essential metabolites in a cell.

(4) Genetic damage

Characteristics of ageing and senescence

- There is general decline in metabolic activities, decline in ATP synthesis and also decreased potency of chloroplast.
 - (2) Decrease in RNA and DNA.
 - (3) Decrease in semipermeability of cytoplasmic membranes.
- (4) Decrease in the capacity to repair and replace wornout cells.
- (5) There may be accumulation of chromosomal aberrations and gene mutations with advancing age. As a result of these changes protein synthesis becomes defective.
- (6) Increased production of hydrolytic enzymes such as proteases and nucleases.
 - (7) Deteriorative change in cell organelles and membranes.
- (8) Decrease in the internal content of auxin and cytokinins and increase in the production of abscisic acid or ethylene.

Importance of senescence : Biologically, senescence and death have following advantages :

- (1) It maintains efficiency since the old and inefficient organs are replaced by young efficient part like leaves, buds, flowers and fruits. etc.
- (2) During senescence, the cellular breakdown results in release of many nutrients including amino acids, amides, nucleotides, simple sugars and minerals. The same are withdrawn from the senescing organs into the main trunk and later utilised in the growth and developed of new parts.
- (3) Shoot senescence is a mechanism to help the plants perennate during the unfavourable periods.
- (4) Simultaneous or synchronous leaf fall occurs in autumn prior to winter. It reduces transpiration, which is essential for survival in winter, when the soil in frozen and roots can not absorb water.
- (5) Litter of fallen leaves and twigs is an important source of humus and mineral replenishment for the soil.

Abscission

The process of shedding of leaves, fruits or flowers by a plant is called abscission. The shedding of plant parts takes place by the formation of a special layer of cells called abscission layer, within the region of attachment. The middle lamella between certain cells in this layer in often digested by polysaccharide hydrolyzing enzymes such as cellulase and pectinases.

Tips & Tricks

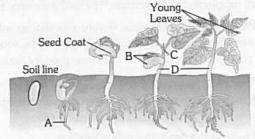

- The double sigmoid growth curve occurs in some fruits e.g., Grapes, plum.
- Measurement of growth in young root by making it at 1mm intervals with Indian Ink was first done by Strasburger
- The development of shoot and root is determined by cytokinin and auxin ratio.
- Mixture of 2, 4-D and 2, 4, 5-T (dioxin) is given the name 'Agent orange' which was used by USA in Vietnam war for defoliation of forests (i.e., in chemical warfare).
- In glass houses when plants are kept on artificial light and temperature, then this method is called phytotron and is applicable in agriculture, horticulture and tissue culture,
- E Phytotron is a method in which plants are grown in controlled environment.
- When each meristem influences other meristems then this phenomenon is called growth correction.
- ABA is used in dryfarming.
- Malic hydrazide is a growth retardant which checks cell division. So during seed storage this is applied for checking sprouting of potato tubers so that the importance of potato may be lowered down.
- Auxin and Cytokinin in combined form shows synergistic effect (affects development of physical structure).
- SDP's contain anthesins and synthesize gibberellic acid for flowering. Whereas LDP's contain GA and synthesize anthesins for flowering.
- Leaves show maximum expansion in violet light.
- & Knott (1934) found that the locus of photoperiodic induction is the leaves.
- Wellensick (1964) found that the locus for perception of cold treatment is the meristmatic cells (at all places) especially the shoot apex.
- Reduced availability of auxin stimulates leaf fall while presence of auxin slows down leaf fall. Cytokinin prevent senescence through stimulating anabolic activity. They are called antiageing hormones Florigen hormone synthesized in the
- Geotropic stimulus is perceived by root cap in case of root by stem apex in case of stem.

Growth

- Maximum growth in roots occurs
 - (a) At apex
- (b) In presence of light
- (c) Behind the apex (d) In presence of soil

The given figure indicates the stages of seed germination 2.

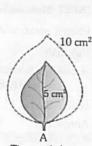

Identify A. B. C and D respectively

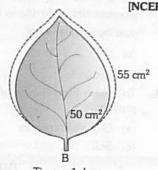

[NCERT]

- (a) Root hair, Cotyledons, Epicotyl and Hypocotyl
- (b) Mesocotyl, Cotyledons, Epicotyl and Hypocotyl
- (c) Radicle, Cotyledons, Epicotyl and Hypocotyl
- (d) Plumule, Cotyledons, Epicotyl and Hypocotyl
- Which of the following instrument can be used to record plant growth by seconds i.e. in fraction of a minute
 - (a) Arc auxanometer
- (b) Arc indicator
- (c) Space marker disc
- (d) Crescograph
- Which two factors primarily affect the developmental phase of growth of plants
 - (a) Light and temperature
 - (b) Rainfall and temperature
 - (c) Light and wind
 - (d) Temperature and relative humidity
- Evergreen trees remain green throughout the year on 5. account of
 - (a) Absence of leaf fall
 - (b) Leaves falling in small numbers at intervals
 - (c) Supply of the moisture throughout the year
 - (d) Cold climate
- The growth involves 6.
 - (a) Cell division
- (b) Cell enlargement
- (c) Cell maturation
- (d) All the above
- Where would you look for active cell division in plants 7.
 - (a) In the pith cells
 - (b) In the cells of cortex
 - (c) In the internodal region
 - (d) At the tip of root and shoot
- Plant growth in length is increased by 8. (a) Apical meristem
- [MP PMT 1998] (b) Lateral meristem
 - (c) Dermatogen
- (d) Periblem
- Growth is
 - (a) Unidirectional backward (b) Reversible
 - (c) Unidirectional forward
- (d) None of the above
- Phytotron is a device by which
 - [CPMT 1995; AIIMS 1998; MH CET 2001]
 - (a) Electrons are bombarded
 - (b) Protons are liberated
 - (c) Plants are grown in controlled environment
 - (d) Mutation are produced in plants
- The S-shaped growth curve and 'grand period of growth' may change with
 - (a) Sudden fluctuation in light intensity
 - (b) Change in temperature
 - (c) Fluctuation in humidity
 - (d) It remains unaffected

See the figure and choose the correct option from table

[NCERT]

Time = 1 day

Time = 1 day

	Α-	Leaf	B-L	eaf
DER P	AGR	RGR	AGR	RGR
(a)	0.5	100%	1.5	100%
(b)	5	100%	5	10%
(c)	100%	5	10%	5
(d)	1%	1	2%	2

- Deeply sown seeds do not germinate and do not come up over due to the deficiency of
 - (a) Light
- (b) Water
- (c) Oxygen
- (d) Nutrients
- 14. The rate of growth of any organism follows [MP PMT 1998]

Typical growth curve in plants is [AIPMT (Cancelled) 2015]

- (a) Hyperbola curve
- (b) J-shaped curve
- (c) Sigmoid curve
- (d) Parabola curve
- 15. Exponential growth occurs in
- [Odisha JEE 2009]
- (a) Yeast
- (b) Asexual reproduction
- (c) Bacterial
- (d) All of these

- 16. Dendrochronology is
- [Kerala CET 2003]
- - (a) Secondary growth
 - (b) Apical growth
 - (c) Seasonal variation
 - (d) Determination of age of tree
- 17. In vascular plants, light promotes
 - (a) Growth
- (b) Development
- (c) Differentiation
- (d) De-differentiation
- 18. In lag phase, the growth is
 - (a) Slowest
- (b) Fastest
- (c) Intermediate
- (d) No growth at all
- 19. To remove seed dormancy by mechanical removing of seed coat is called [DPMT 2003; J & K CET 2008]
 - (a) Stratification
- (b) Scarification
- (c) Vernalization
- (d) Photoperiodism
- Highest growth is found in

[NCERT; Pb. PMT 1999; RPMT 1999; CBSE PMT 2004]

- (a) Static phase
- (b) Exponential phase
- (c) Descending phase
- (d) Lag phase
- The growth in plants is

- (a) Limited
- (c) Unlocalised
- [MP PMT 1999]
- (b) Unlimited
- (d) None of these

- 22. Which of the following is the primary motive force responsible for growth
 - (a) Root pressure
- (b) Turgor pressure
- (c) Osmotic pressure
- (d) DPD
- 23. Given below is a graph drawn on the parameters of growth versus time A, B, C respectively represent

[NCERT; Kerala PMT 2007; AIIMS 2011]

Size

- (a) Exponential phase, log phase and steady state phase
- (b) Steady state phase, log phase and lag phase
- (c) Slow growing phase, lag phase and steady state phase
- (d) Lag phase, steady state phase and logarithmic phase
- (e) Lag phase, log phase and steady state phase
- 24. "Traumatin" is present in
 - (a) Old leaves
- (b) Cork
- (c) Wood
- (d) Injured portion
- 25. Seeds of parasitic plants like Orobanche germinate in the presence of
 - (a) Auxin produced by the roots of the host
 - (b) GA3 produced by the roots of the parasite
 - (c) Exudates of the host plant
 - (d) Exudates of the parasite
- 26. Growth is maximum in the zone of [AFMC 1994]
 - (a) Cell division
- (b) Cell elongation
- (c) Cell maturation (d) All of these
- The instrument by which the rate of growth of stem is accurately measured is [CPMT 1995, 2002;

Kerala CET 2003; J & K CET 2005; Odisha JEE 2012] Or

Growth in length of a plant can be measured by

[Pb. PMT 2004; AMU (Med) 2005; RPMT 2005; HP PMT 2005; AFMC 2010]

- (a) Hydrometer
- (b) Auxanometer
- (c) Osmometer
- (d) Potometer
- Several horticultural techniques are followed for the production of 'bonsai' plants. One of them is drastic pruning of root system. Which of the following physiological factor is involved in that method [CBSE PMT 1990]
 - (a) Inadequacy of mineral nutrients
 - (b) Deficiency of auxins
 - (c) Impairment of water absorption
 - (d) Deficiency of cytokinins
- Distribution of growth in a root by marking it at equal intervals with Indian ink was originally studied by
 - (a) Wellensick
- (b) Strasburger
- (c) Went
- (d) Nitsch
- 30. Classical experiments on growth were performed by
 - (a) Lamarck and Boysen-Jennsen
 - (b) Boysen-Jennsen and Darwin
 - (c) Darwin and Lamarck
 - (d) De Vries and Paul
- The type of growth of bands in conifers is
 - (a) Lateral
- (b) Delinquent
- (c) Caudex
- (d) Excurrent

Growth Hormones

- Among plants 'pheromones' are secreted by the cells of following plants for the given function [BHU 1994]
 - (a) All plants for growth and development
 - (b) Yeast for facilitating mating
 - (c) All fungi for sexual reproduction
 - (d) Rhizopus for the formation of zygospore
- 2. The natural plant hormones were first isolated from
 - (a) Corn germ oil and human urine
 - (b) Cotton fruits, spinach leaves and rice plants
 - (c) Avena coleoptile spinach leaves and the fungus gibberella
 - (d) Human urine and rice seedlings
- 3. Who used the term 'phytohormones' for plant hormone
 - (a) Balis
- (b) Morgan
- (c) Went
- (d) Thimann
- 4. Phytohormones control
- [CBSE PMT 1990]
- (a) Growth
- (b) Physiological functions
- (c) Rooting
- (d) Flowering
- Legume seeds exhibit dormancy because of
 - (a) Undeveloped embryo
- (b) Hard seed coat
- (c) Absence of cytokinin
- (d) Absence of GA₃
- 6. By hormone application it is possible to obtain seedless fruits. In which of the following it is undesirable to obtain seedless fruits
 - (a) Tomato
- (b) Orange
- (c) Watermelon
- (d) Pomegranate (Anar)
- In which of the following respect, the plant hormones differ from enzymes [BVP 2003]
 - (a) Required in less quantity
 - (b) They are expended in the process
 - (c) They release some energy
 - (d) None of the above
- 8. Plant hormones are usually
 - (a) Proteins
- (b) Lipids
- (c) Carbohydrates
- (d) Aromatic compounds
- Whose technique is employed for the extraction and elimination of hormones
 - (a) Beck
- (b) Beer
- (c) Garner
- (d) Allard
- 10. Who for the first time speculated the presence of organ forming substances in plant now called hormones

[MP PMT 2001]

- (a) Darwin
- (b) Went
- (c) Yabuta
- (d) Sachs
- Rhizocalin is a additional hormonal substance which is secreted by
 - (a) Cotyledons
- (b) Roots
- (c) Leaves
- (d) Stem
- Certain chemical substances having profound effect on growth, are called [MP PMT 1997]
 - (a) Catalytic agents
- (b) Phytohormones
- (c) Enzymes
- (d) Compost

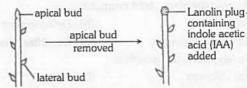

- 13. The pineapple which under natural conditions is difficult to blossom has been made to produce fruits throughout the year by application of [NEET (Karnataka) 2013]
 - (a) NAA, 2, 4-D
- (b) Phenyl acetic acid
- (c) Cytokinin
- (d) IAA, IBA
- To induce formation of organs in a callus it is necessary to provide [MHCET 2015]
 - (a) Growth hormones
- (b) Water
- (c) Soil
- (d) Antibiotics

Auxin

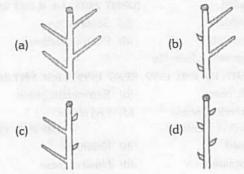

- Leaf fall occurs as abscission layer is formed when the content of [MP PMT 1996]
 - (a) Auxin increases
- (b) Auxin decreases
- (c) Abscisic acid decreases
- (d) Gibberellic acid decreases
- 2. Dr. F. Went noted that if coleoptile tips were removed and placed on agar for one hour, the agar would produce a bending when placed on one side of freshly cut coleoptile stumps. Of what significance is this experiment

[CBSE PMT 2014]

- (a) It supports the hypothesis that IAA is auxin
- (b) It demonstrated polar movement of auxins
- (c) It made possible the isolation and exact identification of auxin
- (d) It is the basis for quantitative determination of small amounts of growth-promoting substances
- 3. Apical dominance in higher plants is due to
- [NCERT]
- (a) Balance between auxin and cytokinin
 - (b) Enzyme activity and metabolism
 - (c) Carbohydrates
 - (d) Photoperiodism
- 4. See the following diagram

After two weeks the appearance of the shoot would be [NCERT]

UNIVERSAL BOOK DEPOT 1960

[NCERT]

- Which one of the following plant function is not generally governed or controlled by auxin [AMU (Med.) 2010]
 - (a) Apical dominance
- (b) Phototropism
- (c) Photosynthesis
- (d) Growth
- Which of the following movements is not related to change in auxin levels [CBSE PMT 1990]
 - (a) Nyctinastic leaf movement
 - (b) Movement of roots towards soil
 - (c) Movement of sunflower tracking the direction of the sun
 - (d) Movement of shoot towards light
- Parthenocarpy is induced by

[KCET 1994]

- (a) ABA
- (b) Auxins
- (c) Zeatin
- (d) Cytokinin
- Who among the following discovered the Avena curvature test to find out the concentration of auxins [NCERT]
 - (a) F.W. Went
- (b) L.J. Audus
- (c) K.V. Thimman
- (d) F. Skoog
- 9. One of the synthetic auxin is

[CBSE PMT 2009]

Or

Flowering in pineapple is promoted by

- (a) NAA
- (b) IAA
- (c) GA
- (d) IBA
- Which of the following is not naturally occurring plant hormone [MP PMT 1996;

CPMT 1999; JIPMER 2001; BVP 2002; KCET 2009]

- (a) 2, 4-D
- (b) GA,
- (c) Gibberellin
- (d) IAA
- 11. Highest concentration of auxins exist in

[CBSE PMT 1990; MP PMT 2000]

- (a) At the base of various plant organs
- (b) Growing tip of plants
- (c) In leaves
- (d) In xylem and phloem cells only
- A well known naturally occurring auxin is or A natural growth regulator (hormone) is
 - (a) 2, 4-D
- (b) Indole acetic acid
- (c) NAA
- (d) Maleic hydrazide
- 13. See the following

Above structure is of an auxin, that is

- (a) IAA
- (b) Auxin b
- (c) Auxin a
- (d) None of the above
- Which one among the following chemical is used for causing defoliation of forest trees [CBSE PMT 1998]
 - (a) Amo-1618
- (b) Phosphon-D
- (c) Maleic hydrazide
- (d) 2, 4-D

- 15. Auxins inhibits the growth of
 - (a) Apical bud
 - (b) Lateral axillary buds
 - (c) Roots on stem cuttings
 - (d) Parthenocarpic development of fruits
- Phototropism in shoots is attributed to
 - C:LL
 - (a) Auxin
- (b) Gibberellins
- (c) Cytokinins
- (d) Abscisic acid
- Differentiation of shoot is controlled by [CBSE PMT 1999]
 - (a) High gibberellin : cytokinin ratio
 - (b) High cytokinin: auxin ratio
 - (c) High auxin: cytokinin ratio
 - (d) High gibberellin: auxin ratio
- How does pruning help in making the hedge dense

[CBSE PMT 2006]

- (a) The apical shoots grows faster after pruning
- (b) It releases wound hormones
- (c) It induces the differentiation of new shoots from the rootstock
- (d) It frees axillary buds from apical dominance
- 19. Both in callus and suspension cultures commonly used auxin is [Kerala CET 2005; Odisha JEE 2012]
 - (a) NAA
 - (b) IBA
 - (c) 2, 4-D
 - (d) 2, 4, 5-Trichlorophenoxy acetic acid
 - (e) Abscisic acid
- 20. Levitt performed experiments. He observed that auxin treated cells were able to absorb water even when kept in hypertonic solution. Which explains this observation best
 - [Manipal 2005]
 - (a) Auxin treated cells lose selective permeability
 - (b) ATP production increases and therefore much energy is available for active absorption
 - (c) Auxin lowers the water potential of cells
 - (d) Auxin increases the solute potential of cells
- 21. Which of the following ion is pulled out in apoplast by the auxin during growth [CPMT 1999]
 - (a) Na+
- (b) K+
- (c) Mg²⁺
- (d) H+
- Pruning of plants promotes branching because the axillary buds get sensitized to [AIIMS 2004]
 - (a) Ethylene
- (b) Gibberellin
- (c) Cytokinin
- (d) Indole acetic acid
- One of the commonly used plant growth hormone in tea plantations is [CBSE PMT (Mains) 2010]
 - (a) Ethylene
- (b) Abscisic acid
- (c) Zeatin
- (d) Indole-3-acetic acid
- 24. Auxin-B was first isolated by
 - (a) Kogl and Erxlaben
 - (b) Kogl, Erxlaben and Haagen-Smith
 - (c) Miller and Skoog
 - (d) Yabuta and Sumiki

BOOK D	744 Plant Growth and Development

30.	Which of the following is not a physiological effect/an	40.	Auxins are abundantly produced in [CBSE PMT 1990; BHU 2008]
	influence of auxin [KCET 2006; Kerala PMT 2012]		(a) Root
	(a) Initiates rooting in stem cuttings		(b) Meristematic region of the root
	(b) Promotes flowering		(c) Shoot
	(c) Prevents fruit and leaf drop at early stages(d) Inhibits the growth of lateral buds		(d) Meristematic region of the shoot
	(e) Promotes bolting	41.	The presence of auxins in a solution could be tested by [MP PMT 1999]
31.	The substances which have proved very effective to induce		(a) Avena sativa stem tip test (b) Carbon tetrachloride test
	rooting from cut end of the stem is		(c) Iodine test (d) Defoliation test
	[EAMCET 1995; BHU 1999; Pb. PMT 2000]	42.	In plants auxin synthesis occurs in
	Or No. 11		[MP PMT 1994; CPMT 1999; KCET 2000] (a) Cortex (b) Phloem cells
	Abscission of fruits is prevented by [Pb. PMT 1999; RPMT 1999]		(c) Root and shoot tips (d) Xylem cells
	(a) Phenyl acetic acid (b) α-naphthalene acetic acid	43.	You are given a tissue with its potential for differentiation in
	(c) Indole acetic acid (d) Indole butyric acid	. OMERATIVES	an artificial culture. Which of the following pairs of
32.			hormones would you add to the medium to secure shoots as well as roots [NEET (Phase-II) 2016]
	elsewhere. The movement of auxin is largely		well as roots [NEET (Phase-II) 2016] (a) Gibberellin and abscisic acid
	[CBSE PMT 2000; KCET 2007]		(b) IAA and gibberellin
	(a) Basipetal (b) Acropetal		(c) Auxin and cytokinin
	(c) Acropetal and basipetal (d) Centropetal		(d) Auxin and abscisis acid

Plant Growth and Development 745 UNIVERSAL BOOK DEPOT 1966 Apical dominance is not affected by Gibberellins [MP PMT 2001] (a) Indole acetic acid (b) Gibberellic acid Gibberellin was first extracted from (c) Indole acetaldehyde (d) Indole butyric acid [CPMT 1993, 94, 96, 98, 2003; AFMC 2006] The hormone which was discovered through 'foolish (a) Gibberella fujikuroi (b) Algae seedling' disease of rice is (c) Bacteria (d) Roots of higher plants [AIIMS 1994; CBSE PMT 2007; BHU 2008] 2. Specific property attributed to gibberellins is **IKCET 20041** Or (a) Shortening of genetically tall plants Bakane disease in paddy is caused by (b) Elongation of genetically dwarf plant [VITEEE 2006; WB JEE 2009] (a) Indole-3-acetic acid (c) Promotion of rooting (b) Ethylene (c) Gibberellic acid (d) Yellowing of young leaves (d) Kinetin 13. Gibberellins were first discovered in fungal genus The hormone involved in metabolism of food material in 3. cereal grain during germination is [DPMT 2003; BVP 2004] [MP PMT 1999] (a) Mucor (b) Rhizopus (a) Auxin (b) CKN (c) Agaricus (d) Fusarium (c) GA (d) None of these The rosette habit of cabbage can be changed by application Cell elongation in internodal region takes place due to of [KCET 2011] [MP PMT 1999; CBSE PMT 2004: (a) IAA (b) GA DPMT 2007; J & K CET 20121 (c) ABA (d) Ethaphon (a) Gibberellins (b) Ethylene At the onset of seed germination, the digestive enzymes amylase are produced by the action of (c) Cytokinins (d) Indole acetic acid Which of the following plant hormone substitutes for long 5. [BHU 2005; AMU (Med.) 2006] photoperiods in flowering plants [BHU 2004] The activity of a amylase in the endosperm of barley (a) Auxins (b) Gibberellins geminating seed is induced by [MP PMT 2002] (c) Cytokinins (d) Ethylene (a) Auxins (b) Gibberellins Gibberellic acid induces flowering [CBSE PMT 1997] (c) Cytokinins (d) Ethylene (a) In some gymnospermic plants only 16. The chemical nature of gibberellins is that they are (b) In long day plants under short day conditions [KCET 2006] (c) In short day plants under long day conditions (a) Acidic (b) Alkaline (d) In day neutral plants under dark conditions (c) Proteinaceous (d) Amines 7. Which one of the following pairs, is not correctly matched The gibberellins are plant growth hormones. They cause elongation of stems. Gibberellin was first isolated by [CBSE PMT 2007] Japanese workers from (a) Abscissic acid - Stomatal closure [CPMT 1993, 94, 2003; (b) Gibberellic acid - Leaf fall AIEEE Pharmacy 2003; DPMT 2004] (a) Endosperm of barley (b) Sporophyte of moss (c) Cytokinin - Cell division (c) A parasitic fungus (d) Scutellum of rice (d) IAA - Cell wall elongation Parthenocarpic tomato fruites can be produced by Cytokinin [CBSE PMT 2006] 1. Cytokinin is a hormone whose main function is (a) Raising the plants from vernalized seeds [AFMC 1997, 2000, 12; CPMT 2000, 10; (b) Treating the plants with phenylmercuric acetate AIIMS 2001; BHU 2004; Odisha JEE 2004] (c) Removing androecium of flowers before pollen grains (a) Induction of cell division and delay in senescence are released (b) To take part in cell division (d) Treating the plants with low concentrations of (c) Refers to cell movements gibberellic acid and auxins (d) To cause dormancy 9. Gibberellins can promote seed germination because of their Richmond Lang effect can be observed in plants by the influence on treatment of [AIIMS 2005; NEET 2013] [MP PMT 1993; Odisha JEE 2012] (a) Cytokinin (b) Ethylene (a) Rate of cell division (c) Abscisic acid (d) Gibberellins (b) Production of hydrolyzing enzymes 3. A plant hormone used for inducing morphogenesis in plant (c) Synthesis of abscisic acid tissue culture is [CBSE PMT 1998] (d) Absorption of water through hard seed coat Or 10. Dormancy of seed is broken by For plant tissue culture among the following which one is [RPMT 2002; Pb. PMT 2004; WB JEE 2016] required (a) Auxin and Cytokinin (b) Gibberellins and ethylene (a) Abscisic acid (b) Gibberellins

(c) Cytokinins

(d) Ethylene

(c) Ethylene and auxin

(d) Cytokinin and auxin

- (c) Both (a) and (b)
- (d) None of the above
- One hormone helps in ripening of fruits while the other stimulates closure of stomata. These are respectively

[Kerala PMT 2008]

- (a) Abscisic acid and auxin
- (b) Ethylene and abscisic acid
- (c) Abscisic acid and ethylene
- (d) Ethylene and gibberellic acid
- (e) Gibberellic acid and abscisic acid
- Match the items in Column I with Column II and choose the correct option

	Column – I	Column - II		
A.	Human urine	1.	Cytokinin	
3.	Gibberella fujikuroi	2.	Auxin	
Ξ.	Herring fish DNA	3.	Ethylene	
).	Ripening fruits	4.	Abscisic acid	
E.	Aged leaves of plants	5.	Gibberellins	

[Kerala PMT 2007]

- (a) A-2, B-5, C-1, D-3, E-4
- (b) A-2, B-3, C-4, D-5, E-1
- (c) A-1, B-5, C-2, D-4, E-3
- (d) A-5, B-4, C-3, D-2, E-1
- (e) A-3, B-2, C-1, D-5, E-4
- Which one of the following generally acts as an antagonist to gibberellins [NCERT; CBSE PMT (Mains) 2012; BHU 2012]
 - (a) Zeatin
- (b) Ethylene
- (c) ABA
- (d) IAA
- 12. Abscisic acid treatment results in
 - c acid treatment results in [CBSE PMT 1991; Odisha JEE 2005; GUJCET 2007; J & K CET 2010]

(a) Leaf expansion

- (b) Stem elongation
- (c) Stomatal closure
- (d) Root elongation

(c) Auxins

(c) Gibberellic acid

(a) Necrohormone

Wound hormone is called

(b) Hormone only(d) Phyllocaline

(d) Abscisic acid

Which plant hormone promotes seed, bud dormancy and 13. [CBSE PMT 1999; causes stomatal closure

Or

AIIMS 1999, 2002; DPMT 2006; WB JEE 2008] Or

Presence of which of the following in seed is associated with dormancu [CBSE PMT 1999; BVP 2002]

Leaf abscission, fruit fall, bud dormancy occurs by which

[CPMT 1998; AFMC 2004; Phytohormone BHU 2006; J & K CET 2010]

(a) IAA

(b) Abscisic acid

(c) GA1

(d) Cytokinin

In the extreme drought condition which of the following plant hormone is produced due to which stomata closes [AMU (Med.) 2005; J & K CET 2012]

(a) ABA

(b) I.A.A

(c) Gibberellin

(d) Ascorbic acid

Choose the wrongly matched pair from the following

[Kerala PMT 2006]

(a) Auxins - "to grow"

(b) Gibberellins - Gibberella fujikurai

(c) Cytokinins - Herring sperm DNA

(d) Abscissic acid - Flowering hormone

(e) Ethylene - Gas hormone

16. Phytotron is [CPMT 2003]

(a) Fish culture

(b) Plant hormone

(c) Animal hormone

(d) None of these

17. The shedding of leaves, flowers or fruits due to change in the hormonal balance in plant is referred as

[J & K CET 2005]

(a) Senescence

(b) Abscission

(c) Photoperiodism

(d) Vernalisation

Which one of the following plant hormones (Phytohormone) 18. [NCERT; MHCET 2000; is known as a stress hormone

MP PMT 2006; WB JEE 2008; AIIMS 2012; **CBSE PMT 2014**]

(a) Gibberellins

(b) Kinetin

(c) Auxin

(d) Abscisic acid

19. Which of hormone is responsible for the following [CBSE PMT 2001] senescence

(a) GA

(b) ABA

(c) Auxin

(d) Cytokinin

Photoperiodism and Vernalization

1. The response of different organisms to the environmental rhythms of light and darkness is called

[CBSE PMT 1998; Kerala PMT 2009]

The effect of daily light period on flowering is called

[CPMT 1999]

(a) Phototaxis

(b) Phototropism

(c) Vernalization

(d) Photoperiodism

With which of the following process Cholodny-Went theory [Odisha JEE 2008] is concerned

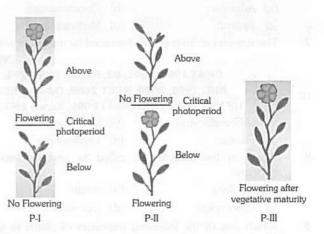

(a) Phototropism

(b) Photomorphogenesis

(c) Photorespiration

(d) Photoperiodism

3. See the following experiment and observe the result

Now identify plants (P - I, II and III)

[NCERT]

(a) P - I = Long day plant; P - II = Long day plant; P - III Day neutral plant

(b) P - I = Short day plant; P - II = Short day plant; P - III = Day neutral plant

(c) P - I = Short day plant; P - II = Long day plant; P - III Day neutral plant

(d) P - I = Long day plant; P - II = Short day plant; P - III = Day neutral plant

The red absorbing form of phytochrome gets converted to the far-red absorbing form after getting irradiated at

[BHU 1994]

(a) 660 nm

(b) 730 nm

(c) 530 nm

(d) 660 nm to 730 nm

The pigment involved in red-far red light interconversion is [CPMT 1994; CBSE PMT 1995, 2002] Or

> The pigment involved in photomorphogenetic movements is [BHU 2000]

> > Or

Pigment involved in photo-perception in flowering is

(a) Cytochrome

(b) Xanthophyll

(c) Lycopen

(d) Phytochrome

Importance of day length (Photoperiodism) in flowering of plants was first shown in

[CBSE PMT 2008; CBSE PMT (Pre.) 2010]

(a) Cotton

(b) Petunia

(c) Lemna (Photoperiodism) (d) Tobacco

Nicotiana sylvestris flowers only during long days and N. tobacum flowers only during short days. If raised in the laboratory under different photoperiods, they can be induced to flower at the same time and can be cross fertilized to produce self-fertile offspring. What is the best reason for considering N. sylvestris and N.tobacum to be [AIIMS 2007] separate species

(a) They are physiologically distinct

(b) They are morphologically distinct

(c) They cannot interbreed in nature

(d) They are reproductively distinct

Plant Growth and Development 749 8. Phytochrome is found in [MP PMT 2007] 21. Photoperiodism is substituted by [MP PMT 2005] (a) Algae (b) Fungi (a) Temperature (b) Mineral nutrient (c) Vascular cryptogams (d) Flowering plants (c) Vit. (d) Iron 9. Effect of length of day (light duration) on flowering is called If plants are given only visible light it's growth will [JIPMER 2001] (a) Phototropism (b) Photoperiodism [MP PMT 2005] (c) Photorespiration (d) None of the above (a) Increase (b) Decrease Saccharum officinarum grows well in 10. [Odisha JEE 2008] (c) Unusual form (d) None of these (a) Low temperature (b) Swampy area Phytochrome occurs in two forms. In which form it promotes (c) Dry and arid condition (d) Moist condition the germination of seeds of some species[CPMT 1995, 2004] When the dark period of short day plants is interrupted by a 11. brief exposure of light, then the plant (a) P_f forms [CBSE PMT 1994] (b) P. forms (a) Will not flower at all (c) Both forms (d) None of these (b) Flower immediately 24. When flowering is regulated by length of day and night, it is (c) Give more flowers called [Odisha JEE 2004; MP PMT 2012] (d) Turn into a long day plant (a) Photoperiodism (b) Phototropism Which of the following hormones can replace vernalization (c) Nyctinasty (d) None of these [BHU 1994] Most of the plants are seasonal due to [MP PMT 1997] Genetic dwarfness can be overcome by treating with (a) Photoperiodism (b) Phototropism [MHCET 2003] (a) Auxin (b) Ethylene (c) Photosynthesis (d) Photolysis (c) Gibberellins (d) Cytokinins Name 'phytochrome' was given by 26. [MP PMT 2001] Which of the following is a short day plant 13. [HP PMT 2005] (a) Mothes (b) Borthwick and Hendrick (a) Wheat (b) Barley (c) Sorokin et al (c) Larkspur (d) Wickson and Thimman (d) Dahlia 27. One set of a plant was grown at 12 hours day and 12 hours What helps in flowering [DPMT 2006; Odisha JEE 2012] night period cycles and it flowered while in the other set (a) Cytochrome (b) ABA night phase was interrupted by flash of light and it did not (c) C-phytochrome (d) Ethylene produce flower. Under which one of the following categories will you place this plant [CBSE PMT 2004] 15. Vernalisation stimulates flowering in (a) Day neutral (b) Short day [NCERT; CBSE PMT (Mains) 2012] (c) Long day (d) Darkness neutral (a) Zamikand (b) Turmeric 28. The low temperature treatment that reduces the period (c) Carrot between sowing and flowering is called [BHU 1999, 2006; (d) Ginger CPMT 2000; DPMT 2003, 04; BVP 2004; 16. Photoperiodic stimulus is received by [MP PMT 1999] AMU (Med.) 2005, 06; HP PMT 2005; Kerala PMT 2006] (a) Leaves (b) Buds (c) Meristem (d) Flowers The practice of subjecting seeds to low temperatures for a 17. Biological clock in plants is controlled by [BHU 2012] period of time in order to cause growth and flowering during summer season is called (a) Phytochrome (b) Cryptochrome [CBSE PMT 1992; WB JEE 2016] (c) Both (a) and (b) (d) Gibberellin (a) Chemotaxis (b) Vernalization 18. The period of suspended growth due to exogenous (c) Freezing injury (d) None of the above condition is termed as [J & K CET 2005] Phytochrome is closely related to [RPMT 1999] (a) Quiescence (b) Dormancy (a) Chlorophyll 'e' (b) Bacterio chlorophyll (c) Phycocyanin 'c' (c) Perennation (d) Carotinoid (d) Hibernation Treatment of seed at low temperature under moist Short day plant is [Odisha JEE 2005] conditions to break its dormancy is called [CBSE PMT 2006] (a) Xanthium (b) Pisum (a) Chelation (b) Stratification (c) Cucumis (d) Avena (c) Scarification (d) Vernalization 20. Through their effect on plant growth regulators, what do the 31. In SDP flowering does not occur IBHU 20031 temperature and light control in the plants (a) When intermediate light is given red \rightarrow far red \rightarrow red [NCERT; CBSE PMT (Mains) 2012] (b) Interrupted by a flash of far light (a) Apical dominance (b) Flowering (c) Interrupted by a flash red → far light (c) Closure of stomata (d) All of these (d) Fruit elongation

BOOK	750 Plant Growth and Development		
32.	The term "photoperiodism" was proposed by or The phenomenon of photoperiodism in plants was discovered by	41.	Photoperiodism affects (a) Vegetative growth (b) Internode elongation
	[MP PMT 1994, 98, 2002, 12]		(c) Seed germination (d) All of these
	(a) Lysenko and Thimman	42.	Florigen is synthesized in [RPMT 1995]
	(b) Blackman and Skoog		(a) Stem (b) Leaves (c) Root (d) Fruits
	(c) Garner and Allard	43.	(c) Root (d) Fruits With respect to photoperiodism, these are long day plant
	(d) Chailakhyan and Borthwick	40.	[MP PMT 2007; GUJCET 2007]
33.	A hypothetical chemical involved in the flowering of plants is or Chemical agent which has important role in flowering is		(a) Wheat, oat, soyabean
	[CBSE PMT 1991]		(b) Wheat, Xanthium, paddy
	(a) Gibberellin (b) Kinetin		(c) Wheat, poppy, soyabean
	(c) Indole acetic acid (d) Florigen		(d) Wheat, poppy, beet
34.	Phytochrome is used in [RPMT 1992; Kerala CET 2001, 03]	44.	Which of the following is a long day plant
	(a) Flowering only		[CBSE PMT 2001; AFMC 2010]
	(b) Seed germination only		(a) Mirabilis
	(c) Transpiration only		(b) Glycine max
	(d) All physiological processes exhibited by the plants such		(c) Mirabilis jalapa
	as seed germination, flowering (photoperiodism), stem		(d) Spinacia oleracea (Spinach)
	elongation and transpiration	45.	What is the action spectrum of photoperiodism
35.	In short day plants (SDP) flowering is induced by	43.	
	[CBSE PMT 1992]		(a) 430 and 660 nm (b) 640 and 660 nm
	(a) Long night		(c) 660 and 730 nm (d) 700 and 900 nm
	(b) Photoperiod less than 12 hours	46.	Proteinaceous pigment which is the centre of activities
			concerned with light is [CBSE PMT 2001]
	(c) Photoperiod shorter than initial value and uninterrupted long night		(a) Phytochrome (b) Chlorophyll
	(d) Short photoperiod and interrupted long night		(c) Anthocyanin (d) Carotenoids
36.	If a tree flowers thrice in a year (October, January and July) in Northern India, it is said to be [CBSE PMT 1997]	47.	A few normal seedlings of tomato were kept in a dark room. After a few days they were found to have become white- coloured like albinos. Which of the following terms will you
	(a) Photosensitive but thermo-insensitive		use to describe them [Bihar MDAT 1995; DUMET 2009
	(b) Thermosensitive but photo-insensitive		CBSE PMT 2014
	(c) Photo and thermo-insensitive		(a) Etiolated (b) Defoliated
	(d) Photo and thermosensitive		(c) Mutated (d) Embolised
37.	For germination of seed, which light is necessary	48.	The wavelength of light absorbed by Pr form o
	[AFMC 1996]		phytochrome is [CBSE PMT 2007]
	Or		(a) 640 nm (b) 680 nm
	Which wavelength of light is responsible for best flowering [MP PMT 2011]		
	(a) Red light (b) Green light	40	
	(c) Far-red light (d) Blue light	49.	Phytochrome is sensitive to [BHU 2001; Pb. PMT 2004]
38.	Phytochrome becomes active in		(a) Red light (b) Far red light
30.	The state of the s		(c) Green light (d) Both (a) and (b)
	[MP PMT 1998; CBSE PMT 1998]	50.	Chrysanthemum flowers either in winter season or in
	(a) Green light (b) Blue light		evening because it is a [J & K CET 2008
	(c) Red light (d) None of these		(a) Short-day plant (b) Long-day plant
39.	Phytochrome is [MP PMT 1993]		(c) Day-neutral plant (d) Mid-day plant
	(a) Absorption of blue light by leaves	51.	Phytochrome is a [NEET (Phase-II) 2016
	(b) Absorption of PR and PFR in reversible manner		(a) Chromoprotein (b) Flavoprotein
	(c) Absorption of red light with wavelength $660m\mu$		
1200	(d) Absorption of far–red light with wavelength $740m\mu$		(c) Glycoprotein (d) Lipoprotein
40.	A pigment concerned with both floral induction and seed germination is [MP PMT 2002; CPMT 2010]	52.	Plants which disregard the requirement of a definite day length for the flowering are called [WB JEE 2016]
	(a) Florigen (b) Chlorophyll		(a) Short day plants (b) Long day plants
	(c) Plastocyanin (d) Phytochrome		(c) Day neutral plants (d) Long short-day plants

Critical Thinking

Objective Questions

- During cell enlargement phase of growth, molecules of new cell wall material are inserted between the original molecules of stretched wall. This process is known as
 - (a) Intussusception
- (b) Apposition
- (c) Integration
- (d) None of the above
- Senescence as an active developmental cellular process in the growth and functioning of a flowering plant, is indicated in [CBSE PMT 2008]
 - (a) Annual plants
 - (b) Floral parts
 - (c) Vessels and tracheid differentiation
 - (d) Leaf abscission
- 3. Phytohormones are

[CBSE PMT 1990; AFMC 2006]

- (a) Hormones regulating growth from seed to adulthood
- (b) Growth regulators synthesised by plants and influencing physiological processes
- (c) Hormones regulating flowering
- (d) Hormones regulating secondary growth
- Identify two physiological processes induced by two different phytohormones having a common precursar which is formed due to the catalytic activity of pyruvic dehydrogenase complex
 - (I) More female flowers in cucumber
 - (II) α-amylase production in barley grain
 - (III) Acceleration of fruit ripening in tomato
 - (IV) Delay in sprouting of potato tubers

The correct combination is

[EAMCET 2009]

- (a) I, II
- (b) I, III
- (c) II, IV
- (d) III, IV
- Choose the correct sequence of stages of growth curve for bacteria [AIIMS 2007]
 - (a) Lag, log, stationary, decline phase
 - (b) lag, log, stationary phase
 - (c) Stationary, lag, log, decline phase
 - (d) Decline, lag, log phase
- Which of the following is more essential for the breaking of seed dormancy [Odisha JEE 2008; MHCET 2011]
 - (a) Light
- (b) Heat
- (c) Cold
- (d) Moisture
- Moving on a grass lawn facilitates better maintenance primarily owing to [JIPMER 1994]
 - (a) Removal of apical dominance and promotion of lateral meristem
 - (b) Removal of apical dominance
 - (c) Wounding which stimulate rapid regeneration
 - (d) None of the above

- Apical dominance means
 - (a) Suppression of growth of apical bud by axillary buds
 - (b) Suppression of growth of axillary buds by presence of apical bud
 - (c) Stimulation of growth of apical bud by removal of axillary buds
 - (d) Inhibition of growth of axillary buds by removal of apical bud
- 9. Clinostat is the apparatus used to
 - (a) Measure the rate of growth in plant
 - (b) Measure the quantity of auxin in plant
 - (c) Measure the effect of light on plant
 - (d) Eliminate the effect of gravity on plant
- Which of the following statement is false with respect to application of auxins
 - (a) Control direction of growth of plants
 - (b) Inhibits lateral bud growth
 - (c) Initiate and promote cell division actively particularly in tissue culture
 - (d) Produce hyperelongation effect
- 11. A green plant bends towards the source of light when exposed to the light on only one side, it bends towards the source of light as it grows. Which of the following is the best explanation of the phenomenon [AIPMT (Cancelled) 2015]
 - (a) The apices of their stems are attracted by light
 - (b) They need light for photosynthesis
 - (c) Some auxins accumulates on the shaded side to induce greater cell elongation on that side
 - (d) Light stimulates the cells on the illuminated side to increase in length
- What will be the effect on phytochrome in a plant subjected to continuous red light [CBSE PMT 1997]
 - (a) Level of phytochrome will decrease
 - (b) Phytochrome will be destroyed
 - (c) Phytochrome synthesis will increase
 - (d) None of these
- Exogenous application of gibberellins induces male flower formation on genetically female plants in
 - (a) Carica
- (b) Cucumis
- (c) Coccinia
- (d) Cucurbita
- 14. A genetically dwarf plant can be converted into a tall plant by the use of [MP PMT 1996]
 - (a) Kinetin
- (b) GA₃
- (c) IAA/X-rays
- (d) 2, 4-D
- 15. One hormone is used to speed up the malting process in barley, another is used to promote flowering in pineapple, while the third helps in the delay of leaf senescence. These are respectively [Kerala PMT 2012; AMU (Med) 2012]
 - (a) Auxin, gibberellin and cytokinin
 - (b) Gibberellin, cytokinin and auxin
 - (c) Gibberellin, auxin and cytokinin
 - (d) Cytokinin, auxin and gibberellin
 - (e) Auxin, cytokinin and gibberellin

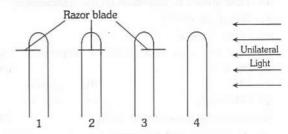

- 16. The ripening of fruits can be accelerated by
 - (a) Reducing the supply of water to plant when fruits are maturing
 - (b) Increasing the supply of nitrogen to the atmosphere surrounding them
 - (c) Warming up the surroundings artificially
 - (d) Artificially adding ethylene gas to the atmosphere surrounding them
- Which one of the following statements is true for the phytochrome [MP PMT 1995]
 - (a) Phytochrome is a phytohormone
 - (b) Phytochrome is a photosynthetic pigment
 - (c) Phytochrome is a pigment that controls growth, photomorphogenesis and development of many plants
 - (d) Phytochrome is a regulatory protein that controls several dark-dependent developmental processes
- 18. Which one of the following synthetic growth regulators is used to promote synchronized flowering in pineapple

[KCET 2010]

- (a) Benzyl aminopurine
- (b) Phenylmercuric acetate
- (c) Indolebutyric acid
- (d) 2-chloroethylphosphoric acid
- 19. Which one of the following pairs is incorrectly matched

	and we experience of the		[NCERT; Kerala PMT 2011]
(a)	Adenine derivative	-	Kinetin
(b)	Carotenoid derivative	-	ABA
(c)	Terpenes	10.70	IAA
(d)	Indole compounds	-	IBA
(e)	Gas	10	Ethylene

- 20. The viability of seeds is tested by [NEET (Karnataka) 2013]
 - (a) 2, 6 dichlorophenol indophenols
 - (b) 2, 3, 5 triphenyl tetrazolium chloride
 - (c) DMSO
 - (d) Safranine
- The given figure shows four coleoptiles set up at the start of an experiment

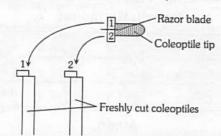

Which two coleoptiles will bend towards the light source

[NCERT]

- (a) 3 and 4
- (b) 2 and 3
- (c) 1 and 4
- (d) 1 and 2

UNIVERSAL BOOK DEPOT 1960

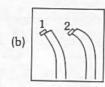

22. Two blocks of Agar 1 and 2 were kept in the positions shown in the diagram below for several hours and then transferred into two freshly cut coleoptiles

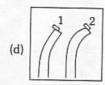

After two days of growth which of the following would result

INCERT

- 23. One hormone hastens maturity period in juvenile conifers, a second hormone controls xylem differentiation, while the third increases the tolerance of plants to various stresses they are respectively [KCET 2015]
 - (a) Gibberellin, Auxin, Cytokinin
 - (b) Auxin, Gibberellins, Cytokinin
 - (c) Gibberellin, Auxin, ABA
 - (d) Auxin, Gibberellins, ABA
- Which of the following enhances or induces fusion of protoplasts
 [AIPMT (Cancelled) 2015]
 - (a) Polyethylene glycol and sodium nitrate
 - (b) IAA and kinetin
 - (c) IAA and gibberellins
 - (d) Sodium chloride and potassium chloride
- 25. Seed dormancy can be broken by the following combination of chemicals [WB JEE 2016]
 - (a) GA3, IAA and ABA
 - (b) KNO3, GA3 and Ethylene chlorohydrin
 - (c) NAA, 2, 4, 5 T and IAA
 - (d) ABA, BAP and GA3
- 26. Seedless fruits can be induced by [WB JEE 2016]
 - (a) ABA and IAA
- (b) ABA and Zeatin
- (c) IAA and GA3
- (d) Ethylene and ABA

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below :

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- Assertion : Gibberellins induce flowering in long day plants.
 - Reason : Genetically tall plantbecome dwarf by application of Gibberellin. [AIIMS 1994]
- 2. Assertion : Agent orange is a mixture of 2,4-D and 2,4,5-T, used during Vietnam War.
 - Reason : 2,4-D and 2,4,5-T are used as herbicides.
- Assertion : Auxins promote apical dominance by suppressing the activity of lateral buds.
 - Reason : In moriculture, periodic pruning of shoot tips is done to make mulberry plants bushy.

[KCFT 2009]

- Assertion : "Touch" responses in Mimosa is an example of such movement.
 - Reason : Nastic movements occur in the direction of stimulus.
- **5.** Assertion : Photomodulation of flowering is phytochrome-regulated process.
 - Reason : Active form of phytochrome (Pfr) directly induces floral induction in shoot buds.

[AIIMS 2004]

- Assertion : Secondary roots and shoots are plagiogeotropic.
 - Reason : Plagiogeotropic roots are those which develop at an angle of 45° from the vertical axis.
- 7. Assertion : The apical bud is the only source of auxins.
 - Reason : Removal of apical bud promotes lateral bud growth.
- 8. Assertion : Cytokinin are antisenescent.
 - Reason : Effects of cytokinins is antagonistic to ethylene.

Answers and Solutions

Growth

- (c) Apex portion of root is made up of protective tissue 'root cap' and region of cell division is situated below the root cap.
- 4. (a) Differential length of light and temperature influence the developmental phase of plant. Photoperiodism and vernalization are the two important factors responsible for the flowering of plants.

- (d) First phase of growth is cell division, second phase is cell enlargement and third phase is cell maturation.
- (d) In apical meristem, tissue actively dividing cells are present.
- (a) Apical meristem are found at shoot and root apex. As a result of activity of these meristems plants increases in length.
- (c) Because growth is a irreversible process.
- 10. (c) In glass houses when plants are kept on artificial light and temperature, then this method is called phytotron and is applicable in agriculture, horticulture and tissue culture.
- **13.** (c) Most plants require oxygen for seed germination. That is why soil is ploughed before sowing the seeds.
- 14. (c) The growth of an organism/organ passes through different phases. If the growth rate of a plant part is plotted against time on a graph paper, a sigmoid/Sshaped growth curve is obtained.
- (a) It represents intial stage of growth. The rate of growth is very slow in lag phase.
- (b) Scarification is mechanical or chemical method to soften/weaken hard seed coat by chipping, filing or machine threshing, hot water, fat solvent, H₂SO₄.
- **20.** (b) Log phase is the rapid growing phase of plants between lag and stationary phase.
- 27. (b) Auxanometer can register total growth, rate of growth at specific time and overall pattern of growth. In arc auxanometer actual growth in length of a plant is measured as

 $\label{eq:actual growth} Actual \ growth = \frac{distance travelled \ by pointer \times radius of pulley}{Length of pointer from centre of pulley}$

- 29. (b) Measurement of growth in young root by marking it at 1mm intervals with Indian ink was first done by Strasburger.
- 30. (b) The existence of first plant growth hormone came from the work of Darwin and Darwin. They found that bending movement of coleoptile of canary grass was due to exposure of tip to unilateral light. Boysen-Jenson found that the tip produces a chemical which was later named auxin.

Growth Hormones

- (d) Growth hormones are also called phytohormomes term given by Thimann (1948).
- (b) Seed of many plants including the leguminosae, Malvaceae. Chenopodiaceae, Convolvulaceae and Solanceae have very hard seed coats. Such seed coats are impermeable to water.
- 6. (d) By parthenogenesis, seedless fruits are produced but in pomegranate, this process is inapplicable because in it seeds are important.
- 7. (a) Growth of the plant is very much regulated by certain chemical substances (hormones), which are synthesized by the plant in very small quantities. They are needed in small quantities at very low concentrations as compared to enzyme.
- (c) Rhizocaline is also called as root forming hormone and it is produced by the leaves and translocated in a polar manner down the stem.

UNIVERSAL BOOK DEPOT 1960

756 Plant Growth and Development

Auxins

- (b) Auxin inhibits abscission of leaves and fruits. Abscission layer is produced when the auxin content falls below a minimum.
- 2. (c) F.W. went isolated auxin from Avena coleoptile tip.
- (a) Presence of auxin causes apical dominance in plants and cytokinins are responsible for breaking of apical dominance.
- (c) Because photosynthesis is enzymatic reaction and it is anabolic process.
- (b) In presence of auxins unfertilized ovary get changed into fruit.
- 10. (a) 2, 4-D (2, 4-dichlorophenoxy acetic acid) is a artificial
- (d) 2, 4 dichlorophenory acetic acid is used as a defoliant for broad leaved plants.
- 23. (d) Auxins are commonly use in hedge making.
- 27. (b) Because ethylene is responsible for ripening of fruits. Auxins promote elongations and growth of stems and roots and enlargement of many fruits by stimulating elongation of cells in all direction.
- 28. (a) Weeds are undesirable in a field with a crop that causes poor yeild. 2, 4-D is a famous herbicide or weedicide by which broad-leaved weeds can be destroyed but does not affect mature monocotyledonous plants.
- 29. (b) Abscission layer is produced when the auxin content falls below a minimum. Application of auxin retards the abscission of leaves, fruits, branches, etc.
- 31. (d) Many new plants are usually propagated by stem cutting. If we dip to the lower cut end of a cutting in dilute solution of auxins (especially IBA) very soon large number of roots are developed on the cut ends due to which these cutting develop into successful plants.
- 32. (a) Auxin show polar movement. It is basipetal (from apex to base) in stem but acropetal (from root tip towards shoot) in the root.
- 34. (b) 2, 4-D is a selective weedkiller. It is highly toxic to broad-leaved plants. It increases carbohydrate metabolism to such an extent that the plants burn themselves to death in dicots.
- 36. (a) Natural auxins are synthesized in physiologically active parts of plants such as shoot apices, leaf primordial and developing seeds, bud, embryos from amino acid tryptophan
- 38. (b) Hormones are secreted by cells in one part of the plant and produce their effect in other part of the plant.
- 39. (a) Avena curvature test carried out by F.W. Went demonstrated the effect of auxins on plant growth by performing some experiments with the oat (Avena sativa) coleoptile. IAA is the natural auxin.
- (c) Auxins and cytokinin induce development of root and shoot in a culture medium (respectively)

Gibberellins

- (a) Gibberellins was extracted from rice seedling suffering from 'bakanae disease' which is caused by Gibberella fujikuroi fungus.
- 2. (b) Gibberellins are weakly acidic hormones having gibbane ring structure which cause cell elongation of intact plants in general and increased internodal length of genetically dwarfed plants (i.e., corn, pea) in particular.
- (c) GA hormone promotes RNA, protein and enzyme synthesis. They helps in germination process.
- 4. (a) The gibberellins induce elongation of the internodes. The elongation of stem results due to rapid cell division and cell elongation induced by gibberellins.
- (b) The GA induced bolting in rosettes is exploited commercially to induce early production of seeds.
- 6. (b) When long day plant are grown under short day conditions the gibberellins are produced in insufficient quantities and flowering does not occur. However if the plant is transferred to long day conditions or gibberellin solution is applied to leaves flowering occurs.
- 7. (b) Gibberellic acid is mainly related with elongation of plant.
- 9. (b) Aleurone layer of endosperm releases α -amylase and protease hydrolytic enzyme, which promotes seed germination.
- 10. (b) Aleurone layered α -amylase promotes breaking of seed dormancy.
- (b) GA promote only plant elongation but the apical dominance by auxins.
- 12. (c) In 19th century, Japanese farmers observed that the seedlings of rice were abnormally elongated due to infection of fungus Gibberella fujikuroi. This effect is called as foolish seedling disease.
- (d) GA Ist discovered from Gibberella fujikuroi (Fusarium moniliforme) which is of ascomycetous fungus.
- **15.** (b) GA enhances seed germination by enhancing α -amylase sunthesis and thus overcomes dormancy.
- (c) Gibberella fujikuroi is the ascomycetous fungus, which is parasitic in nature.

Cytokinin

1. (a) The cytokinin is a true cell division factor, promotes meristematic tissue regions. The cytokinin prevents distruction of chlorophyll in leaves. In presence of kinin the rate of mitotic cell division gets increased. Under this effect when green leaves are kept in cytokinin solution then they become green for long time. So this effect of cytokinin is called as Richmond–Lang effect of senescence.

Plant Growth and Development 757

- 2. (a) Cytokinins delay the senescence of leaves and other organs by controlling protein synthesis and mobilization. Reported by "Richmond and Lang" in 1957 working on "Xanthium leaves"
- (c) Cytokinin is a plant hormone which plays a part in organ formation (morphogenesis) with auxin.
- (b) Cytokinesis formation of cell after the karyokinesis in the cytoplasm of cell.
- 5. (c) Cytokinins help in delaying senescence.
- (b) Cytokinin promotes flowering in some SDP like Lemna, Wolffia.
- 7. (b) Bio chemically the cytokinin is aminopurines.
- (b) In liquid endosperm of coconut kinetin (cytokinins) are present.
- 12. (a) Cytokinin concentration are highest in meristematic regions and area of continuous growth such as root, young leaves, developing fruits and seed.
- 13. (b) Cytokinin prevents decolouration of chlorophyll study under Richmond – lang effects. Cytokinin increase shelf life of vegetables and cut flowers and keep them fresh for longer time by preventing deterioration of protein chlorophyll.
- 14. (b) Kinetin induces cell division.
- (b) Cytokinin promotes RNA synthesis in nuclei after treatment.
- 18. (b) Letham first synthesized cytokinin from corn milk.

Ethylene

- (a) Ethylene retards the flowering in most of the plants but increase flowering in pineapple in off season.
- 4. (a) Ethylene is gaseous hormone which stimulates transverse or isodiamteric growth but retards the longitudinal one.
- (d) Ethylene is a gaseous plant hormone and it is responsible for fruit ripening.
- 11. (d) Root development and root hair formation C_2H_4 .
- 12. (a) Suitable combination of gases in atmosphere for fruit ripening is 80% ethylene (C_2H_4) and 20% CO_2 .
- (d) As ethylene inhibits longitudinal growth but stimulates transverse growth.

ABA and Other growth regulators

- (d) Spray of abscisic acid causes very fast abscission of leaves, and also causes dormancy of buds and seeds.
- (b) Because IAA, NAA and GA are growth promoters and ABA is growth inhibitor.
- (d) Seed germination is limited and hence abscisic acid induces dormancy of seeds and buds.

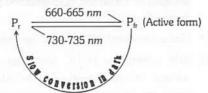

- (a) Wound hormone is also called as traumatic acid or necrohormone.
- (a) Maleic hydrazide is a growth retardant which checks cell division.
- (a) Morphactins are synthetic growth regulators which act in variety of ways on the natural regulation mechanism of plants.
- (b) Morphactins have inhibitory efficient on the stem elongation. Increased concentration produces dwarfing in the plants.
- 11. (c) Gibberellins and ABA are antagonistic with each other.
- 12. (c) ABA inhibits the H⁺|K⁺ exchange and promotes the leakage of maleic acid. The reduction of osmotically active solutes would render the guard cells flaccid and keep the stomatal pore closed.
- 13. (b) Abscisic acid (also called stress hormone) is a mildly acidic growth hormone which function as a general growth inhibitor by counteracting other hormones (auxin, gibberellin, cytokinin) or the reactions mediated by them. ABA induced bud dormancy, seed dormancy closure of stomata and stopage of cabial activity.
- 18. (d) The synthesis of abscisic acid is stimulated by drought, water logging and other adverse environmental condition. Therefore, it is also called as stress hormone.
- 19. (b) Abscisic acid stimulates senescence of leaves by causing destruction of chlorophyll and inhibition of protein and RNA synthesis.

Photoperiodism and Vernalization

- (d) Photoperiodism is the term to denote a biological response to changes in the ratio of light and darkness in a 24 hour cycle.
- (a) In phototropism according to Cholodny Went theory, unilateral light produces more auxin and hence more growth on the shaded side resulting in bending.
- (a) Phytochrome exists in two interconvertible forms. The red (660 nm), absorbing form Pr and far red (740 nm), absorbing from Pfr.
- 5. (d) Phytochrome is responsible for absorption of red and far red light and it is involved in red-far red light interconversion. According to Buttler in 1959, light absorbing pigment are called as phytochrome. These are proteinaceous substances in which coloured pigment is chromatophore.
- (d) Phytochrome is chromoprotein (Photosensitive) photoreceptor, blue pigment protein complex, found in almost all flowering plants (angiosperms).
- (a) If dark period of SDP is interrupted, the plant will not have flower because in SDP, dark period is critical and necessary for flowering.

758 Plant Growth and Development

- 12. (c) The stimulus of vernalization in known as vernalin. The stimulus of vernalization that induce flowering could be a particular gibberellin or a mixture of gibberellins. If GA is sprayed on the single gene dwarf plants, genetic dwarfism is overcome and plants become long e.g., maize, pea, etc.
- 14. (c) Phytochrome is an amorphous photoreceptor protein pigment. It exists in two states, i.e., phytochrome Red (P_r) and phytochrome far-red (P_{fr}).

It is considered that during the day $P_{\rm fr}$ form of the phytochrome is accumulated in the plant which is inhibitory to flowering in short-day plants but is stimulatory in long day plants.

- 16. (a) Photoperiodic stimulus is perceived by mature/old leaves.
- 20. (b) Flowering is induced by light temperature.
- (b) Because in vernalized plant 'vernalin' substance is produced which is responsible for flowering.
- (c) Phytochrome is bright blue or bluigh green pigment which is similar to phycocyanin.
- 30. (b) In stratification apple, plum, seeds, are exposed in well areated, moist condition under low temperature of 0 - 10° C for weeks of months.
- 32. (c) The effect of photoperiod on flowering was discovered by Garners and Allard at USA in 1920 in case of Maryland mammoth variety of Tobacco which is an SDP.
- 33. (d) Florigen: In the process of flowering, this hypothetical hormone is applied which is gibberellin in nature.
- 34. (d) In photoperiodism, photoreceptor pigment called phytochrome are in fully developed mature leaves which receive the stimulus of light.
- 35. (c) In SDP the dark period is critical and must be continuous. If this dark period is interrupted even with a brief exposure of red light, the short day plant will not flower.
- 36. (b) Since flowering can take place during any part of the year therefore the plant is not sensitive to photoperiod.
- (a) Red light of 660 nm stimulates germination in positively photoblastic seeds.
- 38. (c) Phytochrome occurs in two i.e., Pr. (Red light) and Pfr. (far red light) and both are interconvertible. It is considered that during day time Pfr form accurnulates in plants which is inhibitory to flowering in SDP During night Pr form accumulates in plants which is stimulatory to flowering.

- 43. (d) Long-day plant will be induced to flower only when the period of available light exceeds a given critical or limiting period. Wheat, poppy, oat, beet etc. are longday plants.
- **45.** (c) Because two types of phytochrome is present in plants i.e., P_{660} and P_{730} .
- 47. (a) Etiolation is depigmentation in leaf when plant is placed in dark for more than 36 hrs. Plants get etiolated in dark, because chlorophyll is not synthesized in darkness.
- **48.** (a) Actual absorption spectrum of P_R is 660 which is not in answer so answer may be 640 nm.
- 52. (c) Day neutral plants flowering in plants is not affected due to variation in photoperiod. (Day length and night length)

Critical Thinking Questions

- (a) During enlargement phase of growth new particles of cellulose are deposited between particles of the old wall, is known as intussusception.
- (b) Phytohormones are biochemical substances which regulates physiology of the plants.
- 7. (b) Sometimes apical bud inhibits the growth of lateral buds, it is called apical dominance. By moving on a grass lawn apical buds are removed and apical dominance of grass is breaked.
- (b) The apex inhibits the growth of axillary bud is called apical dominance.
- (d) Clinostat (= klinostat) is an instrument which can eliminate the effect of gravity and allow a plant to grow horizontally by slowly rotating it.
- (c) Because cytokinins initiate and promote cell division actively in plants tissue and tissue culture.
- (c) Accumulation of auxin at the apex of the plant, which is responsible for the phototropism movement so that plant cells are elongated.
- 12. (d) If phytochrome P_{660} is exposed to red-light, it changes to P_{730} and if P_{730} is exposed to far-red light, it changes quickly back to P_{660} because both are in interconvertible form.
- 14. (b) GA is sprayed on these single gene dwarf plants, genetic dwarfism is overcome and plants become long e.g., maize, pea.
- 16. (d) Ethylene is unique in that it found only in gaseous form, and accelerates ripening of fruits, leaves abscission and promotes senescence.
- (c) Phytochrome is pigment which regulates growth and development like, photoperiodism, chloroplast development, leaf abscission and senescence etc.

Assertion and Reason

- (c) Application of GA can induce flowering in long day plants. It has no favourable effect on size of flower and fruit in certain plants. The genetically dwarf plants can be made tall by application of GA.
- 2. (b) The first selective herbicides to be discovered and used widely were 2,4-D and its derivatives. These compounds are very potent auxins. 2,4-D and 2,4,5-T destroy dicots weeds. They block their seive elements and disturb mitosis. The plant is ultimately destroyed. Agent orange, which was used in the war in Vietnam as a defoliant is an effective mixture of free 2,4-D and the N-butyl ester of 2,4,5-T.
- 3. (a) Auxin is produced by shoot tip and acts as a growth promoter for apical bud and inhibit the growth of lateral buds. When a terminal bud is removed, the nearest axillary buds begin to grow and the plant branches rapidly. In case of mulberry plants, pruning is done to remove apical dominance and causes more branching of the main body of the plant.
- 4. (c) Nastic movements are non-directional movements in which the response is determined by the structure of the responsive organ and not the direction of the stimulus. "Touch" responses in Mimosa are an example of movements that do not necessarily occur towards or away from the stimulus. The movement is produced due to turgor changes in the cells of pulvinus or swollen area lying at the base of the petiole, pinnae and pinnules.
- 5. (c) Phytochrome is a receptor pigment present in leaves. They are responsible for flowering in plants. Phytochrome are two types P_r (Red light) and P_f (far-red light) P_{fr} are responsible for flowering in LDP.
- 6. (a) Secondary roots and shoots are plagiogeotropic that is, they grow to a position at an oblique angle (45°) to the gravitational force. Root and stem branches lie at an angle other than 90° to the direction of gravity.
- 7. (e) The apical bud is not the only source of auxins. Young developing leaves also produce auxins and it has been shown that auxins from this source may inhibit lateral bud growth. When the apical bud is removed, the lateral buds sprout. However, if a paste of auxin is painted on the cut end of the decapitated shoot, the lateral buds remain inhibited, as if the apical bud is present.
- 8. (b) When cytokinins are added directly to the abscission layer, senescence of the zone is retarded. This delayes the degradation of protein and chlorophyll of the plant parts and hence delays senescence. As they act as antisenescent, they act as antagonistic to ethylene which accelerate senescence.
- 9. (b) In most fruits the rate of respiration will undergo a sharp rise and then fall near the end of ripening. Kidd and West termed this phenomenon "climacteric rise". The climacteric acts as a trigger that sets in progress those changes that rapidly transform the fruit from an unripe to a ripe condition. Finally, application of ethylene to unripe fruit will bring on a premature climacteric and accelerate ripening.

- 10. (b) Stratification of seeds may affect the disappearance of inhibitors and the buildup of germination promoters such as the gibberellins and cytokinins. Natural stratification occurs when seeds shed in the fall are covered with cold soil, debris and snow. In artificial stratification, layers of seeds are alternated with layers of moistened Sphagnum sand or some other appropriate material are stored at low temperatures.
- 11. (c) If total growth is plotted against time, an S-shaped or sigmoid curve is obtained. It consists of four parts-lag phase, log phase, phase of diminishing growth and stationary phase. Growth is slow in the lag phase, rapid during log or exponential phase, slow again during the phase of diminishing growth. Growth stops completely during the stationary phase. Log phase is also called as grand phase of growth due to fast growth in this phase.
- 12. (c) It has been demonstrated that flowering in plant is more of a response to the dark period than to the light period. In short day plants, plants can flower in complete darkness if supplied with exogenous nutrients. Flowering is prevented in them if dark period below the critical level is interrupted by a flash of light. Interruption of light by dark inhibits flowering under normal photoperiods.
- 13. (a) Phototropism is a paratonic directional growth movement of curvature which is induced and determined by the direction of light stimulus. Shoots grow towards the source of light hence called positively phototropic while roots grow away from the source of light hence called negatively phototropic.
- 14. (c) Light energy become effective when it is absorbed by a pigment. These pigments are called phytochromes. It occurs in two forms namely P_r and P_{fr}. The two forms are interconvertible. The P_r form absorbs red light of 660 nm and changed to P_{fr}. The P_{fr} form absorb far red light of 730 nm and changed to P_r. The P_r form stimulates whereas P_{fr} form inhibit flowering. P_{fr} form of phytochrome is the active form. The P_r form is not considered to be active.
- 15. (c) Cajlakhjan, working on floral initiation, coined the term florigen for the flowering hormone thought to be present in photoinduced leaves and plants. It is supposed that leaf prepare a special compound A on receiving CO₂. A on turn produces B in dark and is followed by formation of C (florigen). The florigen translocates from vegetative meristems to floral initiation.
- 16. (b) Many plants do not come to flower before they experience a low temperature. These plants remain vegetative during the warm season, receive low temperature during winter, grow further and then bear flowers and fruits. Vernalization is, therefore, a process of shortening of the juvenile or vegetative phase and hastening flowering by a previous cold treatment. The stimulus of vernalization is perceived only by the meristematic cells, e.g., shoot tip, embryo tips, root apex, developing leaves etc.

- (b) Higher amounts of auxin and lower amounts of cytokinin
- (c) Higher amounts of cytokinin and lower amounts of
- (d) Auxin and cytokinin in equal amounts
- Which of the following plant material is widely used in the preparation of culture medium
 - (a) Pinus longifolia
- (b) Cocos nucifera
- (c) Borassus flabellifer
- (d) Cycas revoluta
- 5. Exponential growth in plants can be expressed as

[Kerala PMT 2011]

- (a) $L_t = L_0 + rt$
- (b) $L_e = L_t rt$
- (c) $W_1 = W_0 e^{rt}$
- (d) $W_1 = W_0 ert$
- 6. Which Hormone is responsible for vernalization [MP PMT 2011]
 - (a) Florigen
- (b) Colchicine
- (c) Abscission
- (d) Vernalin
- Antiauxin used in picking cotton balls is
 - (a) NPA
- (b) 2-4D
- (c) TIBA
- (d) Both (a) and (c)
- A substance which is used to stimulate the increase in size of the apple fruit is [NCERT]
 - (a) Morphactin
- (b) Promalin
- (c) Ethylene
- (d) Ethapone

- Storage sprouting of potato can be prevented by
 - (a) IAA
- (b) Maleic hydrazide
- (c) Cytokinins
- (d) Gibberellins
- 10. A substance isolated from herring sperm DNA and named as 'kinetin' by [NCERT]
 - (a) Miller
- (b) Skoog
- (c) Saltza and Strong
- (d) All the above

Answers and Solutions

- (a) The term vernalisation was coined by Lysenko to the method of accelerating the flowering ability of biennials or winter annuals, by exposing their soaked seeds to low temperatures for a few weeks.
- (a) It is more delicate instrument and gives magnification upto 10,000 times. It uses as a root auxanometer.
- (b) Because liquid endosperm of Cocos nucifera possesses kinetin (cytokinin) growth hormone which is responsible for rapid cell division in culture medium.
- 8. (b) Promalin is a mixture of cytokinin–6-benzaldenine, GA₄ and GA₇. It is very active in stimulating increase in apple size particularly in red delicious apples.
- 9. (b) Maleic hydrazide: It is a growth retardant which checks cell division. So during seed storage this is applied for checking sprouting of potato tubers so that the importance of potato may not be lowered down.
- (a) Isolation and identification of kinetin, (6furfurylaminoprine) from nucleic acid preparations, was first reported by Miller (1956).

Chapter

5.1

Digestion and Absorption

Animals are not able to synthesise their own food, therefore they depend on ready-made food for their nutritional requirements. The term nutrition refers to the sum total of all the processes related with the conversion of the raw foodstuff into the stuff of the body to supply energy for different metabolic activities and also for the repair and growth. In other word we can define nutrition as the process by which an organism derives energy to work and other materials, required for growth and maintenance of the various activities of life.

Food intake: Different organisms obtain food in different ways but carry out similar chemical reactions to utilize it. To take food, protozoans use pseudopodia, flagella or cilia; sponges and mussels, a current of water; Hydra, tentacles beset with stinging cells; planarians and earthworms, a muscular pharynx; flukes and leeches, oral sucker; insects and other arthropods, mouth parts of various kinds; and seastars and sea urchins, tubefeet. Sharks capture prey with the jaws; frog and lizard with the tongue; birds with beaks of sorts; rabbit and hare use forepaws, lips and teeth; cattle, lips and teeth; carnivores, claws and teeth; giraffes, tongue; elephants, proboscis (trunk); humans, monkeys and apes use hands.

Digestion

The process by which complex food is converted into simplest food with the help of digestive enzymes (Hydrolytic enzymes) is called digestion. Hence process of digestion is a hydrolytic process.

Types of digestion

(1) Intracellular: When the process of digestion occurs within the cell in the food vacuole. Examples: Protozoa, Porifera, Coelenterata and free living platyhelminthes.

(2) Extracellular: When the process of digestion occurs outside the cell. Examples : Coelenterates and phylum platyhelminthes to phylum chordata.

Digestive system of human

Digestion in vertebrates occurs in the digestive tract or alimentary canal. The various parts involved in digestion can be broadly grouped in two groups -

- (i) Digestive tract or alimentary canal
- (ii) Digestive glands

Digestive tract or alimentary canal

On the basis of the embryonic origin, the alimentary canal of vertebrates can be divided into three parts -

- (1) Fore gut / Stomodaeum: Ectodermal. It includes buccal cavity / oral cavity, pharynx, oesophagus, stomach and small part of duodenum.
- (2) Mid gut / Mesodaeum : Endodermal. It includes small intestine, and large intestine.
- (3) Hind gut / Proctodaeum: Ectodermal. It includes anal canal and anus.

Parts of alimentary canal and its histology Mouth

The mouth is a transverse slit bounded by two movable lips or labia, upper lip and lower lip. Upper lip has small ridges on the sides, a tubercle in the middle and a vertical groove (philtrum) above

Vestibule

It is a narrow space between lips and gums in front and gums and cheeks on the sides. Its lining contains mucous glands. In the vestibule, a small median fold of mucous membrane, the superior labial frenulum, connects the middle of the upper lip to the gum and usually a similar but smaller inferior labial frenulum connects the middle of the lower lip to the gum.

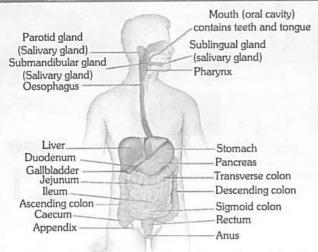

Fig: 5.1-1 Human Alimentary canal

Buccopharyngeal cavity

It includes anterior buccal cavity lined by stratified squamous epithelial cells and posterior pharyngeal cavity lined by columnar epithelial cells. It is distinguished into three region. Pharynx is a vertical canal beyond the soft palate. The food and air passages cross here. Pharynx may be divided into three parts; Nasopharynx, Oropharynx and Laryngopharynx.

Main structures of Buccopharyngeal cavity are -

- (1) **Palate**: The roof of buccal cavity is called Palate. In crocodiles and mammals horizontal shelf like processes of premaxilla and maxilla and the palatine bones of upper jaw fuses and forms a secondary palate which separates the buccal cavity from nasal cavity. Palate is distinguished into three regions –
- (i) Hard palate: Anterior, bony portion formed of maxilla and palatine bones in human and premaxilla, maxilla and palatine bones in rabbit. Hard palate have transverse ridges called palatine rugae. Such rugae or ridges are more developed in carnivorous mammals because their function is to firmly grip the food and prevent it from slipping out the cavity.
- (ii) **Soft palate**: Posterior soft part, made up of connective tissue and muscles.
- (iii) Vellum palati/uvula: Posterior most part of soft palate, which hangs in the region of pharynx. It closes the internal nostrils during degglutition.
- (2) Palatine glands: Numerous mucous glands. Chiefly present in soft palate, secretes mucous for lubrication.
- (3) Naso-palatine duct : One pair, present in rabbit, extends from nasal passage to the buccal passage, contains Jacobson's organ concerned with olfaction.
 - (4) Vibrissae: A tuft of hairs on upper lip of rabbit.
- (5) Hare-cleft: A cleft on the upper lip of rabbit, which makes it bilobed.

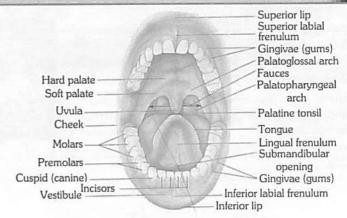

Fig: 5.1-2 Structures of the Oral cavity

(6) Tongue (linguae): Ectodermal, single, pinkish, oval, elongated highly muscular (mesodermal) and protrusible present on the floor of buccopharyngeal cavity the cells present are stratified squamous epithelial cells. A furrow termed the sulcus terminalis divides the oral part and pharyngeal part of the tongue. The limbs of the sulcus terminalis run laterally and forward from a median pit, named the foramen caecum.

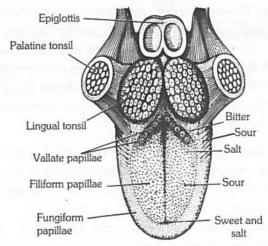

Fig : 5.1-3 Locations of papillae and areas of taste on the tongue

Posterior part of tongue (endodermal) is attached with hyoid, middle one with the floor of buccopharyngeal cavity with the help of frenulum lingum and anterior part is free. The tongue is provided with two specialized structure viz. lingual papillae and lingual glands or weber's gland. Lingual glands are the mucous glands, which secretes mucous. Lingual papillae are numerous, minute projections chiefly present on the dorsum of the tongue. All these lingual papillae can be grouped as simple lingual papillae and taste papillae. Taste papillae are of following types —

- (i) **Circumvallate**: Circular largest 8-12 in number, present in the posterior part of the tongue extending from one side to another. They possess taste buds. These are the largest of all the papillae.
- (ii) Fungiform: Mushroom shaped (Fungi shaped), numerous, present at the anterior margins and tip of the tongue. They have 200 taste buds.

UNIVERSAL BOOK DEPOT 1960

- (iii) Foliate: Leaf like flat, less 8-10 in number, present at the posterior margin of the tongue. They are absent in human and found in rabbit.
- (iv) Filiform: Conical shaped, smallest and most numerous distributed throughout tongue. They are without taste buds.

Hence, in human taste is recognized with the help of circumvallate and fungiform taste papillae. In man the anterior end of tongue feels sweet taste, posterior part feel bitter taste, sides feel sour taste and a small part behind the anterior end feel salty taste.

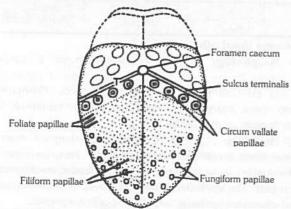

Fig: 5.1-4 Dorsal surface of human tongue, showing three kinds of papillae and some other associated structures

Functions of tongue: Important function of tongue are as follows –

- (i) Acts as universal toothbrush, as it helps in tooth cleaning.
- (ii) Helps in speaking.
- (iii) Helps in degglutition.
- (iv) Helps in mixing saliva with food.
- (v) Acts as a curry comb in many animals, hence help in body cleaning.
 - (vi) Helps in taste detection.
- (vii) In dog helps in regulation of body temperature. The phenomenon is called as "Panting".
 - (viii) In frog and other animals, it helps in prey capturing
- (7) **Teeth**: Teeth is a living structure. On the basis of embryonic origin, teeth in vertebrates are of following two types –
- (i) Horny/ectodermal/epidermal/false teeth: The teeth which develops only from ectoderm. Examples Cyclostomes, tadpole larva of frog, prototherian mammals etc.
- (ii) **True teeth**: The teeth which develops from both ectoderm and mesoderm. Examples Fishes, amphibians, reptiles, eutherian mammals etc.

Differentiation of teeth : Morphologically, teeth can be distinguished as homodont or heterodont.

- (i) Homodont: When all the teeth are structurally and functionally similar. Examples – Vertebrates except metatherian and eutherian mammals.
- (ii) **Heterodont**: When the teeth are different in structure and functions. They are distinguished into four types incisors, canines, premolars and molars. Examples metatherian and eutherian mammals.

- (a) Incisors: These are the front teeth borne by the premaxillae in upper jaw and tips of dentaries in lower jaw. They are single-rooted monocuspid and long, curved and sharp-edged. They are adapted for cutting or cropping and biting.
- (b) Canines: There is one pointed canine in each maxillary of upper jaw and each dentary of lower jaw next to the incisors. They are meant for piercing, tearing and offence and defence. They are single rooted and monocuspid.
- (c) Premolars: They have one root (only in upper first PM two roots) and two cusps (bicuspid). They are meant for crushing, grinding and chewing.
- (d) Molars: They have more than two roots (upper molars have three roots and lower molars have two roots) and 4 cuspid.

Attachment of teeth : On the basis of attachment of teeth at their bases with the jaw bones, teeth can be differentiated into –

- (i) Acrodont: Teeth are attached to the free surface or summit of the jaw bone, as in a shark or frog. Such teeth are apt to break off easily but are replaced.
- (ii) Pleurodont: In this condition, common in urodeles and lizards, teeth are attached to the inner side of jaw bone by their base as well as one side.
- (iii) **Thecodont :** Such teeth are characteristic of mammals. Teeth have well developed roots implanted in deep individual pits or sockets called alveoli or theca, in the jaw bone. These type of teeth also present in crocodilians, fossil toothed bird (Archeaeopteryx).

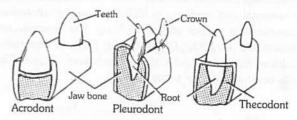

Fig: 5.1-5 Methods of attachment of teeth on jaws

Succession of teeth: According to their replacement (succession), teeth can be divided into 3 categories: polyphyodont, diphyodont and monophyodont.

- (i) Polyphyodont: In lower vertebrates, teeth can be replaced an indefinite number of times during life. e.g., – Fishes, amphibia, reptilia.
- (ii) **Diphyodont :** In most mammals teeth develop during life in two successive sets, a condition known as diphyodont. Teeth of the first set are known as deciduous teeth or milk teeth or lacteal teeth whereas the second set is called permanent teeth.
- (iii) Monophyodont: In some mammals such as platypus, marsupials, moles, sirenians, toothed whale etc. only one set of teeth develops known as monophyodont condition.

Types of cheek teeth

- (i) Bunodont: Crown with small, blunt and round cusps as in man, monkey, pig etc. found in mixed diet mammals.
- (ii) Secodont: With sharp cutting edges for tearing flesh as in carnivores.

- (iii) **Lophodont**: Only one cusp is present with transverse ridges called lophos, e.g., Elephant.
- (iv) Selenodont: With vertical crescentic cusps as in grazing mammals like cow, sheep and goat. Selenodont teeth are two types –
- (a) Brachyodont: Normal low crowned selenodont teeth with large roots are termed brachyodont. e.g. Ground squirrel, cattle.
- (b) Hypsodont: In large grazing mammals teeth are elongated, prism shaped with high crown and low roots. e.g. Horse.

Structure of teeth: Teeth divided into three parts -

- (i) **Root**: Inner most, attached to the bone with the help of cement (hyaluronic acid).
- (ii) **Neck**: Middle, small, covered with gum. Gum provides strength to the teeth.
- (iii) Apex or crown: External exposed part of teeth. Longest part, white in colour.

A small cavity present inside teeth called as pulp cavity or dentine pulp cavity. It contains blood vessels, lymphatic vessels, nerve fibres, connective tissue etc. and provides nutrition to odontoblast cells or osteoblast cells. The odontoblast cells are mesodermal in embryonic origin forming immediate covering of the pulp cavity. The cells secrete dentine/ivory. Bulk of tooth in a mammal is formed of dentine. Dentine is a layer of inorganic substances (62-69%), which surrounds the odontoblast cells. It origin. Enamel, secreted mesodermal in Ameloblast/Enameloblast cells, forms the outermost covering. It is ectodermal and made up of 92% of inorganic substances, hence considered as hardest part of the body. The inorganic substances present are [Ca₃(PO₄)₂,Ca(OH)₂.H₂O] Calcium phosphate (85%), Calcium hydroxide and Calcium Carbonate. Cement/Cementum attaches the tooth root to the bone.

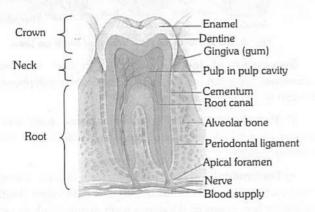

Fig: 5.1-6 Structure of tooth

Dental formula : Each mammalian species is characterized by its own specific dentition with a definite number and arrangement of teeth. Hence, dentition is of taxonomic importance. It is expressed by a dental formula as below —

Rabbit:
$$i\frac{2}{1}, c\frac{0}{0}, pm\frac{3}{2}, m\frac{3}{3} = \frac{8}{6} \times 2 = 28$$
 or briefly,

$$\frac{2033}{1023} = \frac{2+0+3+3}{1+0+2+3} \times \frac{2}{2} = \frac{16}{12} = 28$$
($i = \text{incisors}; c = \text{canines}; pm = \text{premolars}; m = \text{molars}$)

Horse and pig	$\frac{3.1.4.3}{3.1.4.3} \times 2 = 44$	Cat	$\frac{3.1.3.1}{3.1.2.1} \times 2 = 30$
Dog	$\frac{3.1.4.2}{3.1.4.3} \times 2 = 42$	Squirrel	$\frac{1.0.2.3}{1.0.1.3} \times 2 = 22$
Lemur	$\frac{2.1.3.3}{2.1.3.3} \times 2 = 36$	Rat	$\frac{1.0.0.3}{1.0.0.3} \times 2 = 16$
Man (adult set)	$\frac{2.1.2.3}{2.1.2.3} \times 2 = 32$	Elephant	$\frac{1.0.0.3}{0.0.0.3} \times 2 = 14$
Cow	$\frac{0.0.3.3}{3.1.3.3} \times 2 = 32$	Human set (milk set)	$\frac{2.1.0.2}{2.1.0.2} \times 2 = 20$

Table: 5.1-1 Dental formulae of some common mammals

Oesophagus (food tube)

- (1) **Morphology**: Single, ectodermal, dorsal to trachea, approximately 25 cm long. passes through thoracic cavity and opens into stomach present in abdominal cavity. Oesophagus anteriorly opens into pharynx through gullet and posteriorly into stomach through cardiac orifice.
- (2) **Histology**: Serosa is absent but outermost layer of connective tissue is called *as* tunica adventitia. Muscular layer are striated/voluntary in anterior region and unstriated/involuntary in posterior part. The epithelial lining is made up of non-keratinized stratified squamous epithelial cells. Goblet cells are present.

Oesophagus lack digestive glands but multicellular glands are found, which extends upto submucosa. Due to the presence of these submucosal mucous glands, submucosa of oesophagus is thickest than other parts of alimentary canal.

Function: Conduction of food.

Stomach

(1) Structure: Single oval, elongated, unilobed present within abdominal cavity below diaphragm. It consists of three parts as cardiac/fundic (anterior), corpus/body (middle, chief part) and pyloric (posterior part) in human, whereas in rabbit stomach is bilobed and consists of three parts as cardiac (Anterior), fundic (middle, chief part) and pylorus (posterior). Two types of valves are present in the stomach viz. Cardiac sphincter valve between oesophagus and stomach and pyloric sphincter valve between stomach and duodenum. In new born baby cardiac sphincter is much less developed that is why regurgitation of gastric contents is very common. Inner surface of stomach is raised into numerous longitudinal folds called gastric rugae. In case of ruminant mammals (cud chewing mammals) oesophagus consists of only skeletal or voluntary muscles.

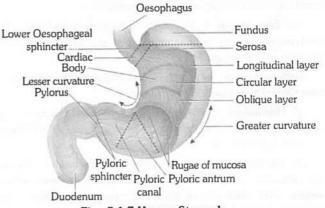

Fig: 5.1-7 Human Stomach

- (2) **Histology**: Outermost layer is serosa. Muscular layer is three layered with outer longitudinal, middle circular and inner oblique. Muscles are involuntary and unstriated. Epithelial lining is made up of simple columnar epithelial cells and specialized cells present in the gastric glands. The nomenclature of gastric glands is according to the parts of the stomach. Various types of gastric glands and the cells present in them are as follows –
- (i) **Anterior part**: Cardiac gastric glands in rabbit and human. Cells present are mucous neck cells secreting mucous.
- (ii) **Middle part**: Fundic gastric/Main gastric glands in rabbit and corpus in human has at least four distinct types of cells –
- (a) Peptic or zymogenic or chief or central cells :
 Secretes two digestive proenzymes pepsinogen and prorennin.
- (b) Oxyntic or parietal cells: Secretes HCl and castle's intrinsic factor required for the absorption of vitamin B_{12} . Hyperacidity is abnormally high degree of acidity due to the secretion of large quantity of HCl i.e. gastric juice.
 - (c) Mucous neck cells: Secretes alkaline mucous.
- (d) Argentaffin cells or Kultchitsky or enterochromaffincells: Responsible for the secretion of vasoconstrictor seratonin.
- (iii) **Posterior part :** Pyloric gastric glands in rabbit and human-cells are mucous neck cells secreting mucous and some cells, called "gastrin" or "G" cells, secrete a hormone, named gastrin, which increases the motility of gastric wall and stimulates gastric glands for active secretion.

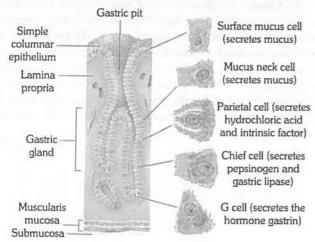

Fig: 5.1-8 L.S. Gastric gland

Functions

- (1) Storage of food.
- (2) Trituration or churning of food to mix with gastric juice.
- (3) Functions of gastric juice (discussed along with gastric juice).

Stomach of ruminants (cud-chewing mammals): The stomach of cattles have four parts, as rumen (paunch), reticulum(honeycomb), omasum (psalterium) and abomasum (rennet). Some authors believe that first three chambers are parts of

the oesophagus, the fourth chamber is the real stomach secreting HCl and enzymes. The embryological studies have proved that all the chambers are parts of the real stomach. Camel and deer lack omasum. Reticulum is the smallest part and its cells are provided with water pockets for the storage of metabolic water.

In the rumen, food undergoes mechanical and chemical breakdown. Mechanical breakdown results from through churning brought about by muscular contractions and aided by cornified surface of villi. Chemical breakdown is caused by symbiotic microorganisms (bacteria and ciliates) that release enzyme cellulase, which act on cellulose and simplify it into short-chain fatty acids, such as acetic acid, butyric acid, propionic acid. This is called microbial digestion.

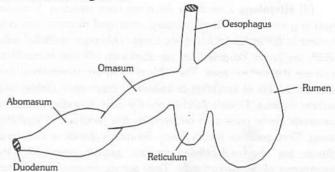

Fig: 5.1-9 The compound stomach of a ruminant

Small intestine

- (1) Structure: Endodermal, longest part of alimentary canal present in the abdominal cavity, supported by a peritoneal membrane called mesentery. Wall of jejunum and ileum has circular or spiral internal fold called fold of kerckring or valvulae conniventes. Also numerous finger like projection called villi project from the wall of lumen, increasing internal surface area about ten time. The distal end of ileum leads into the large intestine by ileocaecal valve in man but in rabbit sacculus rotundus and ileo-coecal valve both are present.
- (2) **Parts**: It is approximately 3 metres in human. It is divisible into three parts duodenum, jejunum and ileum.

Table: 5.1-2 Parts of small intestine

Duodenum	Jejunum	lleum
(Proximal part)	(Middle part)	(Posterior part)
25 cm. Long Forming U-shaped loop before leading to jejunum, pancreas lies in the loop.	About 1 m long and about 4 cm. wide. Wall is thicker and more vascular. Villi thicker and tongue-like. Plicae best developed. Peyer's patches are lacking.	About 2 m long and about 3.5 cm. wide. Wall is thinner and less vascular. Villi thinner and finger-like. Plicae less developed. Peyer's patches are present.

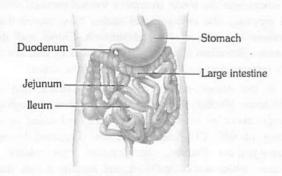

Fig: 5.1-10 Human intestine

(3) **Histology**: Serosa is the outer most covering. Muscular layer is generalized with involuntary, unstriated muscles. The cells present in the epithelial lining are simple columnar epithelial cells, which are brush-bordered *i.e.* provided with villi and microvilli to increase the surface area. The folds present are longitudinal and are called folds of kerckring or valvulae canniventes. Goblet cells secrete mucous. Peyer's patches are the oval, rounded masses of lymphatic tissue present in between lamina propria and epithelial lining. They produce lymphocytes. Brunner's glands or Duodenal glands are the multicellular mucous glands present in the submucosa of duodenum only. They secrete mucous. In addition there are also found granular arogyrophil cell.

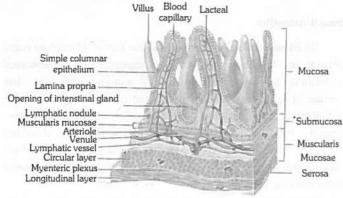

Fig: 5.1-11 Three dimensional view of layers of small intestine showing villi

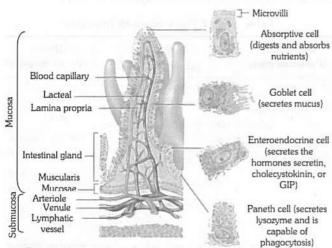

Fig: 5.1-12 Enlarged villus showing located, capillaries intestinal glands and cell types

(4) **Glands of small intestine**: Various glands found in small intestine. Each gland has three types of cells: (1) Undifferentiated epithelial cell (2) Zymogenic cell (paneth cell) and (3) Argentaffin (Enterochromaffin cell).

Table: 5.1-3 Glands of small intestine

Brunner's glands	Peyer's patches	Crypts of Leiberkuhn
Found in duodenum only.	These are lymph nodules.	Known as intestinal gland.
Mucus secreting gland as so known as mucus gland.	They produce lymphocytes. Lymphocytes are	Found in duodenum and ileum only.
	phagocytic in nature which destroy harmful bacteria.	Secrete succus entericus i.e intestinal juice.
Appear (Francis		Formed by folding of lamina propia.

Function: Digestion and absorption of food.

Large intestine

The name large intestine is due to large diameter (4-6 cm).

- (1) **Structure**: Endodermal, approximately 1.5-1.75 metre long.
 - (2) Parts: They are following -
- (i) **Caecum**: Spirally coiled 6 cm long in human and 45 cm long in rabbit. Its posterior end is present as a blind sac in abdominal cavity called vermiform appendix. Vermiform appendix is vestigeal but contains lymphatic tissue. Caecum in human is concerned with passage of food whereas in rabbit it is concerned with cellulose digestion and conduction of food.
- (ii) **Colon:** Single endodermal approximately $1.3\ m$ long in human distinguished into four limbs as ascending, transverse, descending and pelvic or sigmoid limb. Colon posses two specialized structures as Taeniae coli (present in the middle of colon) and Haustra, (dilated sac-like or pockets like structures surrounding taeniae). Colon is concerned with absorption of water of undigested food, 5%, salts, vitamins etc. hence concerned with faeces formation. Colon bacteria also synthesized vit. B_{12} and K.

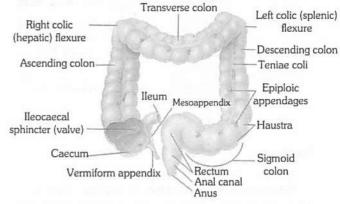

Fig: 5.1-13 Anterior view of large intestine showing major regions

(iii) **Rectum**: Single small dilated sac like in human whereas large beaded in rabbit. It is concerned with storage of faeces. Rectum has strong sphincter muscle in its wall. The sphincter keeps the canal as well as anus, closed when not used for defecation.

(iv) Function: Absorption of water from undigested food.

Anal canal and anus : Anal canal connects rectum with anus and it is about 3 cm. long. Anus is the terminal inferior opening of alimentary canal, which is guarded by an internal involuntary sphincter and an external voluntary sphincter.

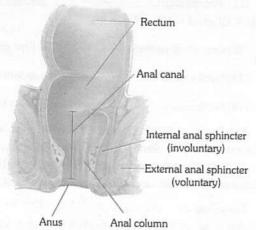

Fig: 5.1-14 Frontal section of anal canal

Digestive glands

The various types of digestive glands present in mammals are salivary glands, gastric glands, intestinal glands, pancreas and liver. The digestive glands secrete digestive juices. Parasympathetic nervous system increases the secretion of digestive juice whereas sympathetic nervous system decreases it.

- (a) Salivary glands: The three pairs of salivary glands present in humans are as follows -
- (1) **Parotid**: One-pair, largest salivary gland present below pinna. A stenson's duct arises from each gland, opening in vestibule between the 2nd molar teeth of upper jaw and cheeks. Parotid glands secrete enzymes. Viral infection of parotid glands causes "Mumps" (by paramyxo virus).
- (2) Sub-mandibular / sub-maxillary: One-pair, present at the junction of upper and lower jaw in cheek region. A wharton's duct arises from each gland and opens on lower jaw. These are seromucous glands.
- (3) **Sub-lingual**: One-pair, present in the floor of buccopharyngeal cavity. These are mucous glands 6-8 ducts, called ducts of rivinus or Bartholin's duct arises from these glands and opens below tongue on the floor of buccopharyngeal cavity.

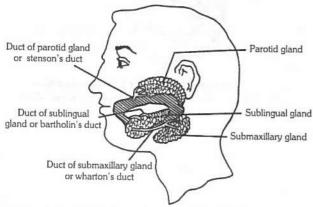

Fig: 5.1-15 Location of salivary glands in man

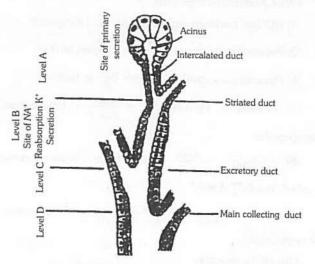

Fig: 5.1-16 An acinus of salivary gland

Saliva / salivary juice : The secretion of salivary glands is called saliva or salivary juice. Some of the characteristics are as follows –

- (1) Amount: 1.0-1.5 litre/day
- (2) Chemical nature: Slightly acidic.
- (3) pH: 6.3 6.8
- (4) Control of secretion: Autonomic reflex (parasympathetic nervous system increases salivation while sympathetic nervous system inhibit secretion.)
- (5) Chemical composition: Water (99.5%), mucous (acts as lubricant), salts (NaCl, $NaHCO_3$ etc.), enzymes (ptyalin, lysozyme) etc.

Functions: Salivary juice and its enzymes -

- (1) Makes the medium slightly acidic for the action of its enzyme.
 - (2) Help in taste detection, deglutition, speaking etc.
- (3) Starch Ptyalin/Diastase Maltose + Isomaltose + Limit dextrin.
 - (4) Bacteria (living) Lysozyme → Bacteria killed.

Gastric glands: There are approximately 35 million of gastric glands present in human stomach and grouped into three categories as already described along with stomach. The gastric gland secretes gastric juice.

Gastric juice

- (1) Amount: 2-3 liters/day.
- (2) Chemical nature: Highly acidic
- (3) pH: 1.0 3.5 (due to presence of HCI)
- (4) Control of secretion : By gastric hormone.
- (5) Chemical composition: Water (99%), mucous, inorganic salts, castle's intrinsic factor, *HCI* (0.5%, conc.) and enzymes prorennin and pepsinogen and gastric lipase.

Functions of gastric juice and its enzymes

- Inactivates the action of ptyalin.
- (2) Makes the medium acidic for the action of gastric enzymes.

- (3) HCl kills micro organisms.
- (4) HCI kills the living organism (prey etc.) if ingested.
- (5) Pepsinogen (inactive) \xrightarrow{HCl} Pepsin (active).
- (6) Prorennin (inactive) \xrightarrow{HCI} Rennin (active).
- (7) Proteins + Peptones $\xrightarrow{\text{Pepsin}}$ Polypeptides +

Oligopeptides.

- (8) Casein $\xrightarrow{\text{Rennin}}$ Paracasienate Above phenomenon is called "curdling of milk".
- (9) Lipids Gastric Lipase → Triglycerides +

Monoglycerides.

- (10) HCl is antiseptic.
- (11) It act as preservative.

Lactose intolerance: Among mammals, man alone takes milk even after becoming adult. In some humans, secretion of lactase decreases or ceases with age. This condition is called lactose intolerance. Lactose intolerant persons fail to digest lactose of milk. In their large intestine, lactose is fermented by bacteria, producing gases and acids.

Intestinal glands : Intestinal glands in mammals is a collective name for crypts of Lieberkuhn (secretes alkaline enzymatic juice) and Brunner's glands (secretes mucous). Intestinal glands secrete intestinal juice.

Succus entericus (intestinal juice)

- (1) Amount: 1.5 2.0 I/day.
- (2) Chemical nature: Alkaline.
- (3) pH: 7.6-8.3
- (4) Control of secretion: Nervous and hormonal (Enterocrinin
- (5) Chemical composition: Water (99%), mucous, inorganic salts, enzymes etc.

Function of Intestinal juice and its enzymes.

- (1) Inhibits the action of gastric enzymes.
- (2) Makes the medium alkaline for the action of it's enzymes.
- (3) Starch Amylase → Maltose + Isomaltose + limit dextrin.
- (4) Maltose $\xrightarrow{\text{Maltase}}$ Glucose + Glucose.
- (5) Isomaltose Isomaltase Glucose + Glucose.
- (6) Lactose (milk sugar) $\xrightarrow{\text{Lactase}}$ Glucose +Galactose.
- (7) Sucrose (cane sugar) $\xrightarrow{\text{Sucrase / Invertase}}$ Glucose + Fructose.
 - (8) Polypeptides + Oligopeptides $\xrightarrow{\text{Erepsin}}$ Amino acids.

- (9) Trypsinogen (inactive) Enterokinase Trypsin (active).
- (10) Lipids, $\xrightarrow{\text{Lipase}}$ Fatty acids + Glycerol + Monoglycerides.
- (11) Phospholipids Phospholipase → phosphorous + Fatty acids + Glycerol + Monoglycerides.
 - (12) Organic phosphate Phosphatase Free phosphate.
 - (13) Nucleic acid $\xrightarrow{\text{Polynucleotidase}}$ Nucleotides.
 - (14) Nucleosides Nucleosidase Nitrogenous bases.

Pancreas: Single, endodermal, flat, leaf-like yellowish, heterocrine (mixed) gland, present between the ascending and descending limb of duodenum and opens into duodenum through pancreatic duct. It can be divided into following parts –

Exocrine: It is the major part (about 99%) of pancreas. The exocrine tissue of the pancreas consists of rounded lobules (acini) that secrete an alkaline pancreatic juice. The juice is carried by the main pancreatic duct, also called duct of Wirsung, into the duodenum through the hepatopancreatic ampulla (ampulla of vater). An accessory pancreatic duct, also named duct of Santorini, may sometimes lead directly into the duodenum.

Endocrine : Minor part (1% only) also called as islets of Langerhans scattered in the exocrine part. It consist of four various type of cells, as $\alpha(A)$ cells, $\beta(B)$ cells, $\delta(D)$ cells and F or PP cells. α -cells secretes glucagon hormone, β -cells secretes insulin hormone and δ cells secrets somatostatin. The PP or F-cells secrete pancreatic polypeptid hormone to control somatostatin. The secretion passes directly into blood.

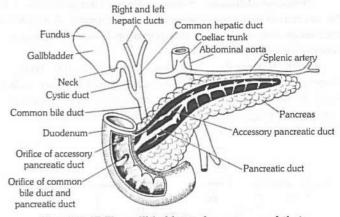

Fig: 5.1-17 The gallbladder and pancreas and their systems of ducts. Both empty into the duodenum, often by a common orifice

Pancreatic juice

- (1) Amount: 1-1.5 //day
- (2) Chemical nature: alkaline
- (3) pH: 7.1-8.2
- (4) Control of secretion: Hormonal and normal mechanism.

UNIVERSAL BOOK DEPOT 1962

Secretin hormones stimulate the production of more alkaline pancreatic juice but low in enzyme content. Pancreozymin or Cholecystokinin stimulates the production of enzyme rich pancreatic juice.

(5) Chemical composition: Water (99%), enzymes and salts.

Functions of pancreas and its enzymes

- (1) The islets of Langerhans secrete insulin and glucagon hormones.
 - (2) The exocrine part of pancreas secretes pancreatic juice.
 - (3) Elastase: It act upon elastin protein.

+ Dipeptides + Oligopeptides.

- (9) Emulsified Lipids

 Steapsin

 (Pancreatic lipase) Fatty acids +

 Glycerol + Monoglycerides.
 - (10) Nucleic acid Nucleosides + Nucleosides.
 - (11) Nucleic acid Nucleosidase Purines + Pyrimidines.
 - (12) Polypeptides Chymotrypsin Oligopeptides.

Liver

(1) **Structure**: The liver is largest and heaviest gland in the body. Its upper and anterior surfaces are smooth and curved to fit the under surface of the diaphragm; the posterior surface is irregular in outline. It consists of three lobes in frog: right, left and median; five lobes in rabbit: left lateral, left central, spigelian, right central and caudate; four lobes in man: right, left, quadrates and caudate lobe. It is divided into two main lobes: right and left lobes separated by the falciform ligament.

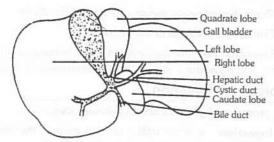

Fig: 5.1-18 Liver of man (ventral view)

A pear-shaped sac, the gall bladder is attached to the posterior surface of the liver by connective tissue. The right and left hepatic ducts join to form the common hepatic duct. The latter joins the cystic duct, which arises from the gall bladder. The cystic duct and

common hepatic duct join to form common bile duct or ductus cholidochus which passes downwards posteriorly to join the main pancreatic duct to form the hepatopancreatic ampulla (ampulla of Vater). The ampulla opens into the duodenum. The opening is guarded by the sphincter of Oddi. The sphincter of Boyden surrounds the opening of the bile duct before it is joined with the pancreatic duct. The basic structural and functional unit of the liver is the hepatic lobule.

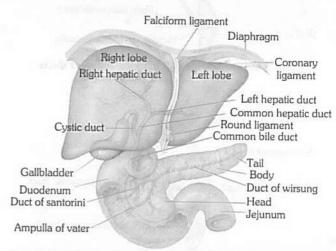

Fig: 5.1-19 Relation of Pancreas to the liver, gallbladder and duodenum

Each lobule is composed of plates of polyhedral, glycogen-rich cells, the hepatocytes, arranged radially around a central vein. Between the plates are radial blood sinusoids. At the periphery of the lobules, the branches of portal vein, hepatic artery, bile ducts, and lymphatics course together. A network of tubular spaces between the hepatocytes represents the bile canaliculi. At the periphery of the lobule the bile canaliculi empty into small hering's canals walled by cuboidal epithelium. These canals lead into bile ducts walled by columnar epithelium. The sinusoids are lined by incomplete endothelium with scattered phagocytic Kupffer cells, that eat bacteria and foreign substances

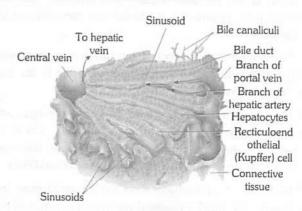

Fig: 5.1-20 Histology of a lobule

Gall bladder: The gall bladder is a slate-blue, pear-shaped sac connected with an supported from liver by a small omentum or ligament. Its distal part is called fundus, while the narrow part, continued as cystic duct, is called the neck.

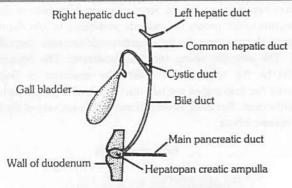

Fig: 5.1-21 Showing gall bladder, different ducts and hepatopancreatic ampulla

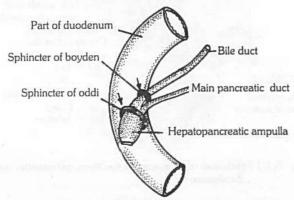

Fig: 5.1-22 Showing sphincter of boyden and sphincter of oddi

Functions of liver: Liver, the largest gland of vertebrate body, is an essential organ, which performs many functions –

- (1) It secretes bile which is a complex watery fluid containing bile salts (Na taurocholate and Na glycocholate), bile pigments (biliverdin and bilirubin), cholesterol, mucin, lecithin and fats etc. It breaks and emulsifies the fat.
- (2) In the liver, haemoglobin of the worn out erythrocytes breaks down to bile pigments bilirubin and biliverdin. The bile pigments are also converted in the bowel into stercobilin which colours the faeces.
- (3) Excess quantities of carbohydrates (glucose) are converted to glycogen (Glycogenesis) in the presence of insulin in the liver cells, and stored therein.
- (4) Glycogen is a reserve food material, which is changed into glucose (Glycogenolysis) and released into the blood at concentrations maintained constant by the liver. In this way, blood-sugar level is maintained under diverse dietary conditions.
- (5) Under abnormal conditions, liver can convert proteins and fats into glucose by complex chemical reactions. Formation of this "new sugar" *i.e.* from non-carbohydrate sources, is called gluconeogenesis.
- (6) If the level of blood-glucose rises beyond normal even after glycogenesis and catabolism, the excess glucose is converted into fat and stored in the liver. The process is termed lipogenesis.

- (7) Amino acids resulting from protein digestion finally come into the liver from the intestine. They are partly released into the blood for distribution and protein synthesis, partly transaminated into other amino-acids and deaminated.
- (8) In the embryo, red blood cells are manufactured by the liver. In the adult, liver stores inorganic salts of iron, copper and vitamin B_{12} (anti–anaemic factor) and thus helps in the formation of red blood cells and haemoglobin.
- (9) Liver functions as a store-house for blood and regulates blood-volume.
- (10) Fibrinogen, prothrombin and certain other blood coagulation factors are formed in the liver. Heparin is an intravascular anticoagulant that is stored in the liver.
- (11) The plasma proteins serum albumin and serum globulin are synthesized by the liver from the amino acids.
- (12) Liver synthesizes vitamin A from the provitamins A (carotenoid pigments). Liver cells also store fat–soluble vitamins A, D, E and K. Besides, it is the principal storage organ for vitamin B_{12} .
- (13) The liver is the site of detoxification of different toxic substances either produced in the body or taken along with food.
 - (14) It is the main heat producing organ of the body.
- (15) Kupffer cells in the liver sinusoids phagocytose and remove bacteria, worn-out blood elements and foreign particles.
 - (16) Liver is an important site of lymph formation.

Bile/chole

- (1) Amount: 800-1000 ml daily. On the average about 700 ml.
- (2) Source: Secreted by hepatic cells
- (3) Storage site: Gall bladder
- (4) Colour: Greenish-blue
- (5) Chemical nature: Alkaline
- (6) pH: 7.6-8.6

Functions of bile

- (1) Emulsification of fats.
- (2) Helps in absorption of fat-soluble vitamins.
- (3) Increases alkalinity to make the medium suitable for enzymatic action.
 - (4) Elimination of heavy metals such as Cu, Hg, Zn etc.
 - (5) Elimination of excess of bile pigments.
- (6) Stercobilin and urobilin (urobilin found in urine) is formed by bilirubin and biliverdin is responsible for colouration of faeces.

Physiology of digestion

The process of digestion involves following steps -

- Ingestion: It is the intake of food most of the animals capture the prey/food with the help of mouth or tongue.
- (2) Mastication: The process occurs in the buccopharyngeal cavity of mammals with the help of teeth. During this process food is broken down into small pieces, which increases its surface area. In frog teeth are not meant for mastication but prevents the escape of prey from mouth.

UNIVERSAL BOOK DEPOT 1960

(3) **Deglutition** / **swallowing**: The passage of food from buccopharyngeal cavity to oesophagus/stomach. In mammals bolus of the masticated food is formed in buccopharyngeal cavity which easily slides into oesophagus. It is a voluntary reflex mechanism. Peristalsis is alternative contraction and relaxation of circular and longitudinal muscles produces the wave of contraction due to which the food passes from front to backward direction in the lumen of alimentary canal. The phenomenon is called as peristalsis. Beside alimentary canal, it is also found in vas deference, ureter etc. Peristalsis is maximum in oesophagus and minimum in rectum.

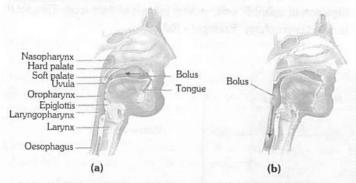

Fig: 5.1-23 Deglutition (swallowing); (a) Position of structures before swallowing, (b) During the pharyngeal stage of swallowing

Antiperistalsis is the peristaltic wave occurring in the reverse direction. It occurs in alimentary canal and results in vomiting. The phenomenon is called as "Regurgitation".

- (4) Digestion: The process by which complex food is converted into simple food with the help of digestive enzymes. The process of digestion in mammals starts in buccopharyngeal cavity.
- (i) **Digestion in buccopharyngeal cavity**: In buccopharyngeal cavity of mammals only starch is digested which is 5% of total food or 20-30% of carbohydrates.
- (ii) **Digestion in stomach**: Chiefly proteins is digested in stomach.
- (iii) Digestion in small intestine: All three component carbohydrates, proteins and fats digested in small intestine with the help of enzymes secreted by pancreas and intestinal glands.
- (5) Absorption: Ingestion and digestion are the first two phases of the physiological processes occurring in the alimentary tract. The third phase is that of absorption by which the digested nutrients are absorb through the wall of gut into blood.
- (i) **Absorption from the mouth :** Normally, there is no absorption from the mouth, but a few drugs may be absorbed into the blood through the mucous membrane, if allowed to dissolve under the tongue, *e.g.*, isoprenaline, glyceryl trinitrate.
- (ii) **Absorption from the stomach**: In the stomach, absorption takes place to a limited degree. The only substances normally absorbed from the stomach are some water, glucose and considerable amounts of alcohol. These substances are absorbed through the walls of the stomach into the venous circulation. Although iron absorption takes place in the small intestine, it is dissolved out of foods most effectively in the stomach in the presence of *HCl*.

(iii) Absorption from the small intestine: The small intestine is the main absorptive organ. About 90% of the ingested foodstuffs are absorbed in the course of passage through the small intestine.

There are two general pathways for the transport of materials absorbed by the intestine; the veins of the hepatic portal system which lead directly to the liver; and the lymphatic vessels of the intestinal area, which eventually lead to the blood by way of the lymphatic system and the thoracic duct.

Absorption of carbohydrates : The products of carbohydrate digestion are absorbed from the intestine into blood of the portal venous system in the form of monosaccharides, chiefly the hexoses (glucose, fructose, mannose and galactose).

Absorption of amino acids and protein: It is probable that under normal circumstances the dietary proteins are almost completely digested to their constituent amino acids and that these end products of protein digestion are then actively transported from the intestine into the portal blood. Surplus amino acids are also withdrawn from portal blood by liver cells and deaminated into ammonia and keto acids. The ammonia is converted to urea and released into blood for excretion by kidneys, while the keto acids are converted to glucose or pyruvic acid and utilized for energy-production or for storage as glycogen and fat.

Absorption of fats: The dietary fat is digested, by the action of the pancreatic lipase present in the intestine, partially into glycerol and fatty acids and partially to split products such as monoacyl glycerols. These products of fat digestion enter the mucosal cells of the small intestine in the forms of micelles, fatty acids and glycerol.

By the lacteals, the fat is carried to the cisterna chyli (meaning 'the receiver of the chyle') and then by the thoracic (lymph) duct to the left branchiocephalic vein, where it enters the blood. The lymph reaching the thoracic duct from the intestines contains an excess of fat giving it a milky appearance. It is called chyle. In this way, fatty acids and glycerol are eventually brought into the blood stream and so, by a circuitous route, to the liver. In the liver, they are reorganized and recombined to form human fat.

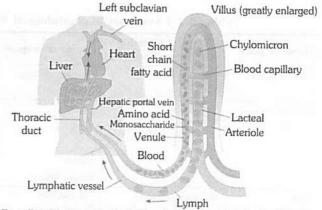

Fig : 5.1-24 Movement of absorbed nutrients into the blood and lymph

Absorption of vitamins : Water-soluble vitamins like members of B complex (except B_{12}) and vitamin C readily diffuse across the walls of the intestine into the blood. The fat-soluble vitamins A, D, E and K are dissolved in micelles, which enter the mucosal cells of the intestine, by simple diffusion. The absorption of these fat-soluble vitamins is markedly decreased in the absence of bile.

(iv) **Absorption in large intestine**: About 100-200 *ml*. of the water of undigested food is absorbed in the colon. It helps in maintaining the body water level. Some amount of mineral salts and vitamins are also absorbed. The symbiotic bacteria (*E. coli*) present in the large intestine, converts the inactive vitamins into active forms (i.e., they synthesizes vitamins (vitamin *B* complex and vitamin *K*) which are absorbed.

- (6) Assimilation: Conversion of absorbed food into active cytoplasm within cell is called as assimilation.
- (7) Faeces formation: The phenomenon occurs in colon due to absorption of water, salts, minerals and vitamins. The peristalsis in colon also helps in faeces formation.
- (8) Egestion / defaecation: The elimination of faeces from the alimentary canal is called egestion or defaecation. The faeces is waste matter discharged from the alimentary canal.

Pseudo-rumination or coprophagy: Animals swallows night faeces and recycle it through the gut to complete the digestion of cellulose and, making full use of their food. This habit is called coprophagy. Example – Rabbit.

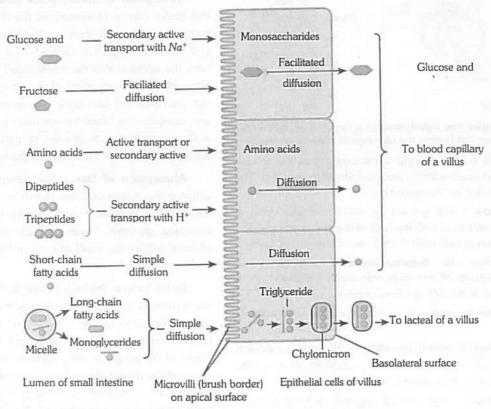

Fig: 5.1-25 Absorption of digested nutrients in the small intestine

Table: 5.1-4 Summary of physiology of digestion Major gastrointestinal enzyme in mammals

Name of gland	Name of digestive juice & optimum pH	Name of enzyme	Site of action	Substrates	Products
Salivary glands	Saliva (6.3 – 6.8)	Ptyalin / Salivary amylase	Mouth	Starch, dextrins, glycogen	Dextrins, maltose, isomaltose and limit dextrin.
Gastric glands	Gastric Juice (1-3)	Pepsin Rennin Gastric lipase	Stomach Stomach	Proteins, casein (Milk) Casein Fats	Peptones, paracasein (curd). Proteoses Paracasein Fatty acid and Glycerol.
Liver	Bile juice (7.6-8.6)	No enzymes	Duodenum	Fat	Makes the food alkaline, emulsifies fat and kills the harmful bacteria.

- 1	IN	焳	ø	ς	Δ			

				Digestion and	Absorption 773 UNIVERSAL BOOK DEPOT
Liver	Bile (7.6 – 8.6)	No enzyme but use and kills harmful bac	ful digestive juice, proteria.	ovides alkaline medium, s	tops the action of HCI. Emulsifies fat
Pancreas	Pancreatic Juice (7.1 – 8.2)	Amylase/Diastase	Small intestine	Starch, dextrins, glycogen.	'Limits' dextrins, maltose, isomaltose.
		Trypsin	Small intestine	Proteins, Chymotry- psinogen (inactive) procarboxy pept- idases (inactive) Fibrinogen (blood) Casein (milk)	Peptides, Chymotrypsin (active carboxy peptidases (active Elastase (active), Fibrin (clo Paracasein (curd)
		Chymotrypsin	Small intestine	Peptones	Peptides
		Carboxypeptidases	Small intestine	Peptides	Smaller peptides and Amin acids.
		Lipase / Steapsin	Small intestine	Triglycerides	Mono-glycerides, fatty acids
		DNAase	Small intestine	DNA	Deoxyribonucleotides
1-4-12-1-1		RNAase	Small intestine	RNA	Ribonucleotides
Intestinal glands	Intestinal Juice (7.5–8.3)	Enteropeptidase (enterokinase)	Small Intestine	Trypsinogen (inactive)	Trypsin (active)
		Aminopeptidase	Small Intestine	Peptides	Smaller peptides and amino acid
		Dipeptidases	Small Intestine	Dipeptides 'Limit dextrins'	Amino acids
		Isomaltase	Small Intestine	Isomaltose	Glucose
		Maltase	Small Intestine	Maltose	Glucose
		Sucrase/Invertase	Small Intestine	Sucrose	Glucose, fructose
		Lactase	Small Intestine	Lactose	Glucose, galactose
		Lipase	Small Intestine	Triglycerides	Monoglycerides, fatty acids
		Nucleotidase	Small Intestine	Nucleotides	Nucleosides, inorganic phosphate
(0)		Nucleosidase Phosphorylases	Small Intestine	Nucleosides Phosphate	Purine, pyrimidine, pentose, phosphate

(9) Hormonal control of digestion: Activities of digestive tract are coordinated by nervous and endocrine systems. Sight and smell of food stimulates nervous system which induces the salivary glands to produce large quantity of saliva, stomach to release its

hormone gastrin and intestine to produce intestinal hormones. Other hormones are produced in sequential order. All of them are polypeptide hormones.

Table: 5.1-5 Gastrointestinal hormones in mammals

Hormone	Source	Stimulus for secretion	Target organ	Action
Gastrin	Mucosa of pyloric stomach	Distension of stomach on food entry	Stomach	Stimulates secretion of gastric juice. Constricts cardiac sphincter.
Enterogastrone	Duodenal epithelium	Chyme entry into duodenum	Stomach	Slows gastric contractions to delay its emptying. Stops secretion of gastric juice.
Secretin	Duodenal epithelium	Acidic chyme entry into duodenum	Pancreas	Release of sodium bicarbonate in pancreatic juice. Steps up secretion of bile.
			Stomach	Inhibits secretion of gastrin.
Cholecystokinin (Pancreozymin)	Duodenal epithelium	Presence of fats in duodenum	Pancreas Gall Bladder	Release of enzymes in pancreatic juice. Release of bile from gall bladder.
Villikinin	Intestinal epithelium	Food in small intestine	Intestine	Accelerates movements of villi.
Duocrinin	Intestinal epithelium (Duodenal mucosa)	Acidic chyme in intestine	Intestine (Brunner's gland)	Release of viscous mucous from Brunner's glands.
Enterocrinin	Intestinal epithelium (Duodenal mucosa)	Acidic chyme in intestine	Intestine (crypts of Lieberkuhn's)	Release of enzymes from Lieberkuhn's crypts.

Nutrition

The substance used for nutrition are called nutrients. Nutreology is the study of food and their use in diet and therapy.

Types of nutrition

- Autotrophic / Holophytic : The individuals, which synthesizes their own food. It can be grouped into two following categories –
- (i) **Photoautotrophs**: The individual, which synthesizes their own food from CO_2 and H_2O in presence of sunlight. Examples Green plants, euglena, green sulphur bacteria, chlorobium.
- (ii) **Chemoautotrophs**: The individuals which synthesizes their food with the help of chemical. Examples Sulphur bacteria, nitrite bacteria, nitrosomonas, nitrifying bacteria–nitrosomonas, nitrobacter etc.
- (2) Heterotrophic: The animals derive organic food materials by consuming bodies or products of other living or dead plants or animals. Heterotrophs are of following three types on the basis of their mode of feeding.
- (i) **Holotrophic or Holozoic :** These individuals ingest mostly solid food. Example Animals.
- (ii) Saprotrophic or Saprobiotic: They feed on dead organic matter. They absorb food through their body surface, organic fluids formed due to putrefaction of dead organism. Example Bacteria, fungi, some protozoans etc.
- (iii) **Parasitic**: These individuals derive their food from the body of their host. These may live inside or upon the bodies of their hosts, or may only periodically visit them for feeding. e.g., Ectoparasites (Lice) and endoparasites (Ascaris, Taenia solium).
- (3) Myxotrophic nutrition: They carry out autotrophic as well as heterotrophic nutrition. Example – Euglena.

Modes of animal nutrition

On the basis of food, holozoic or holotrophic or ingestive nutritionally animals are classified into following –

- (1) **Herbivorous**: The animal which exclusively feeds on plants. Their length of alimentary canal is more as compared to others. Examples Tadpole larva of frog, rabbit, cow, horse, sheep etc.
- (2) Carnivorous: The animal which kills and feeds on other animals. The length of their alimentary canal is minimum. Examples – Tiger, lion etc.
- (3) Omnivorous: The animal which can take both plant and animal product as food. They have maximum type of digestive enzymes. Example – Human, Dog, Prawn.
- (4) Insectivorous: The animal which feeds on insects. Example – Frog, Common bats, wall lizards.
- (5) **Sanguivorous**: The animal which feeds on blood of other animal. Examples Leech, body louse, mosquito, vampire bat etc.
- (6) Carrion Eaters (Scavangers): They feeds on dead animals also termed as scavangers. Examples – Hyaena, neltura, kites etc.
- (7) Cannibalus: Organisms which feeds on its own species. Examples – Cockroaches, some fishes, frog, snakes etc.
- (8) Detritus: Animals feed chiefly upon organic matters present in the humus. Examples – Earthworm.
- (9) Coprophagus or pseudorumination or refection: Animals which feeds on their own faeces. Example – Rabbit, Guinea pig

- (10) Larvivorous: Feeds on larva. Example Gambusia (mosquito fish) and Dragon fly.
- (11) **Frugivorous :** Feeding on fruits. Example Parrot, Bat, Squirrel.
- (12) Food robbers: Feed upon food formed in alimentary canal. Example Ascaris, Taenia solium.
 - (13) Filter feeder: Paramecium, Unio, Sponge.

Feeding mechanism

- (1) Feeding mechanism in liquid feeders (fluid feeders) are as follows –
- (i) Diffusion: Many parasitic organisms (protozoans, tapeworm) absorb the dissolved organic food through general body surface.
- (ii) Pinocytosis (cell drinking): Ingestion of liquid food by invagination through surface of body. Pinocytosis channels are formed at body surface to enclose the fluid food from surrounding medium. Lower ends of channels are pinched off as pinocytic vesicle or pinosomes.
- (iii) **Blood sucking**: Their mouthparts are modified for sucking blood. Examples Vampire bat, mosquito etc.
- (2) Feeding mechanism in microphagus animals (filter feeders): The food of such animals (paramecium, sponges, corals, bivalves, tadpole etc.) is suspended in water fluid and they have filtering devices (clusters of pseudopodia, cilia, flagella, sheets of mucous etc.) or feeding on small microscopic animals like Amoeba, Paramecium etc.

Nutritional requirements

- (1) Food: All living organism needs food. Animals are unable to synthesize their own food hence they obtain it from outside sources. Animals require food for three main purposes, such as food as a fuel which provides energy and material for body maintenance, food for movement of body includes muscles contraction etc., food for growth as well as for the synthesis of body substances.
 - (2) Components of food: These are of following types -
- (i) **Carbohydrates**: They are made up of C: H: O, having H and O in the ratio of 2: 1 and the general formula is $(CH_2O)_n$. They are the chief source of energy. The source of carbohydrates in our food is cereals and pulses.

Table: 5.1-6 Types and examples of carbohydrates

Types of carbohydrate	Examples		
Monosaccharides	Glucose (the main blood sugar)		
	Fructose (found in fruits)		
	Galactose (in milk sugar)		
	Deoxyribose (in DNA)		
	Ribose (in RNA)		
Disaccharides	Sucrose (table sugar) = glucose + fructose		
	Lactose (milk sugar) = glucose + galactose		
	Maltose = glucose + glucose		
Polysaccharides	Glycogen, the stored form of carbohydrate in animals		
	Starch, the stored form of carbohydrate in food		
	Cellulose, part of cell walls in plants; not digested		
	by humans but aids movement of food through intestines		

Specific features

- (1) Storage amount: 900 gm approx.
- (2) Storage site: Chiefly liver and muscles.
- (3) Daily requirement: 500 gm approx.
- (4) Source: Chiefly cereals (rice, wheat, maize), pulses, potato, fruits, sugarcane, milk, honey, sugar etc.
 - (5) Caloric value: 4.1 k cal./gm
 - (6) Physiological value: 4.0 k cal./gm

Functions of carbohydrates

- (1) Carbohydrates, especially glucose, are the main respiratory fuels.
- (2) Ribose and deoxyribose sugars are components of nucleic acids (DNA and RNA). Galactose is a structural component of medullary sheath.
- (3) Monosugars act as monomers for the formation of disaccharides and polysaccharides.
 - (4) Starch and glycogen, serve as reserve fuel.
- (5) Excess of glucose may also be changed into fats (lipogenesis) and stored in liver, adipose tissue and mesenteries.
- (6) Glucose has antiketogenic role as it prevents the incomplete oxidation of fats and formation of ketonic bodies in the blood.
 - (7) Glucose spares the amino acids for protein synthesis.
- (8) Sucrose is the major form in which sugar is transported in the plant body. Sucrose is storage sugar of sugarcane and sugar beet.
- (9) Cellulose, hemicellulose etc. are the main components of cell wall of plants.
- (10) Chitin is main component of cell wall of fungi and exoskeleton of crustaceans.
- (11) Heparin prevents the blood clotting inside the blood vessels (Anticoagulants).
- (12) Glycoproteins form a protective layer, glycocalyx, on intestinal cells.
- (13) Hyaluronic acid acts as a lubricating fluid in the synovial joints between the limb bones.
- (14) Blood antigens like A, B and Rh-factor are glycoproteinaceous and provide immunity to the individual.
- (15) Sugars are also important components of some glycoproteinaceous hormones like FSH (Follicular stimulating hormone), LH (Luteinizing hormone) etc. FSH controls gametogenesis while LH controls the ovulation and formation of corpus luteum.
 - (16) Carbohydrates may be changed into amino acids.
- (17) Oligosaccharides of cell membrane help in cellular recognition.
- (18) Cellulose forms roughage of food which stimulates the secretion of digestive juices. It also helps in peristalsis.
 - (19) Cellulose nitrate is used in explosives.
- (20) Carboxy-methyl cellulose is used in cosmetics and medicines.
- (21) Cellulose acetate is used in preparing cellulose plastics, shatter-proof glass, fabrics etc.
- (ii) **Lipids and fats**: Fats and all fat like substances are called lipids. They are composed of C, H and O. They are insoluble in water but soluble in ether, alcohol, chloroform etc.

Table: 5.1-7 Types of lipids in the body

Types of Lipid	Functions			
Triglycerides (fats and oils)	Protection, insulation, energy storage.			
Phospholipids	Major lipid component of cell membranes.			
Steroids				
Cholesterol	Minor component of all animal cel membranes; precursor of bile salts, vitamin D, and steroid hormones.			
Bile salts	Needed for absorption of dietary lipids.			
Vitamin D	Helps regulate calcium level in the body; needed for bone growth and repair.			
Adrenocortical hormones	Help regulate metabolism, resistance to stress, and salt and water balance.			
Sex hormones	Stimulate reproductive functions and sexual characteristics.			
Eicosanoids	Have diverse effects on blood clotting, inflammation, immunity, stomach acid secretion, airway diameter, lipid breakdown, and smooth muscle contraction.			
Other Lipids				
Fatty acids	Catabolized to generate adenosine triphosphate (ATP) or used to synthesize triglycerides and phospholipids.			
Carotenes	Needed for synthesis of vitamin A. which is used to make visual pigments in the eyes.			
Vitamin E	Promotes wound healing, prevents tissue scarring, contributes to the normal structure and function of the nervous system, and functions as an antioxidant.			
Vitamin K	Required for synthesis of blood-clotting proteins.			
Lipoproteins	Transport lipids in the blood, carry triglycerides and cholesterol to tissues, and remove excess cholesterol from the blood.			

Specific features

- (1) Source: Butter, ghee, liver oil, vegetable cooking oil etc.
- (2) Daily requirement: 50 gm.
- (3) Storage site: Subcutaneous fat, adipose cells.
- (4) Caloric value: 9.45 k cal/gm.
- (5) Actual value: 9.0 k cal/gm.

Functions of lipids

- (1) The fats acts as concentrated fuel. The caloric fuel value of 1 gm of fats is 9.45 kcal, while the physiological fuel value of 1 gm of fats is 9.0 kcal (37 kJ), which is about 2.25 times more than the energy provided by same amount of glucose.
- (2) The fats are also highly suitable for storage as the reserve food material. It is mainly stored in the liver, beneath the skin, in the brown deposits and in the fat bodies. Normally, the fats constitute about 4% of liver by weight.
- (3) Fats stored in the subcutaneous tissue insulate the body against the loss of heat energy, so conserve the body heat. Thus, fats help in homeothermy.

- (4) Medullary sheath is formed of white fatty substance, myelin, which insulates the nerve fibres and prevents the loss of energy.
- (5) Fats forms the protective shock absorbing cushions around a number of organs like the eye balls, kidneys (renal fat), ovaries, etc.
- (6) These help in the absorption of fat-soluble vitamins like A, D, E and K.
- (iii) **Proteins:** They are composed of *C. H. O. N* and some in addition contain *S* and *P*. They are complex, versatile, macromolecules with very high molecular weight. Their unit is amino acids. Out of the 20 amino acids, required in human to build proteins, half of them are essential and rest are non-essential amino acid. Essential amino acids are those, not synthesized by human body and are present in food. The non-essential amino acids are those which can be synthesized by human body.

Table: 5.1-8 Types of amino acids

Dispensable or Essential amino acids	Non-dispensable or Nonessential amino acids		
Arginine	Glycine		
Histidine	Alanine		
Isoleucine	Serine		
Leucine	Aspartic acid		
Methionine	Asparagine		
Phenylalanine	Cystine		
Threonine	Glutamic acid		
Tryptophan	Glutamine		
Lysine	Proline		
Valine	Tyrosine		

Arginine and histidine are considered semi indispensable amino acids. These two are not essential in the adult organisms.

Classification of proteins: They are following types -

- (1) On the basis of structure of molecules
- (i) **Fibrous :** Examples Collagen, myosin, keratin, fibrin of coagulated blood etc.
- (ii) **Globular**: Examples Albumin, globulin, haemoglobin, enzymes, snake venom etc.
- (2) On the basis of their chemical nature: The proteins are divided into three categories –
- (i) Simple proteins: These are formed of peptide chains and yield only amino acids on hydrolysis. On the basis of shape, these may be fibrous proteins e.g. collagen of white fibres, elastin of yellow fibres, keratin of exoskeletal structures like nails, horns, hoofs, hair, feather etc.; globular proteins e.g. albumins and globulin of blood plasma, protamines, histones, glutelins etc.
- (ii) **Conjugated proteins**: These are formed of a proteinaceous and a non-proteinaceous prosthetic group. These include nucleoproteins (of chromosomes-DNA and proteins; and ribosomes-RNA and proteins), glycoproteins (of blood-antigens), phosphoproteins (casein of milk), lipoproteins (lipovitellin of egg-yolk), chromoproteins (haemoglobin of RBCs), haemocyanin, rhodopsin (visual purple), iodopsin (visual violet), cytochromes), metalloproteins (carbonic anhydrase enzyme with Zn^{2+}) etc.

(iii) Derived proteins: These are formed by the partial hydrolysis of simple proteins and include peptones, proteoses etc.

Specific features

- (1) Source: Chief source is pulses, egg, milk, meat, fish, leafy vegetables, soyabean, groundnut etc.
 - (2) Daily requirement: 70-100 gm.
 - (3) Caloric value: 5.6 k cal/gm.
 - (4) Physiological caloric value: 4 k cal/gm.

Table: 5.1-9 Types and functions of protein

Types of Protein	Functions
Structural	Form structural framework or various parts of the body.
	Examples: Collagen in bone and other connective tissues, and keratin in skin, hair, and fingernails.
Regulatory	Functions as hormones that regulate various physiological processes; control growth and development; as neurotransmitters, mediate responses of the nervous system.
	Examples: The hormone insulin, which regulates blood glucose level, and a neurotransmitter known as substance P, which mediates sensation of pain in the nervous system.
Contractile	Allow shortening of muscle cells, which produces movment.
	Examples: Myosin and actin.
Immunological	Aid responses that protect body against foreign substances and invading pathogens.
	Examples: Haemoglobin, which transports most oxygen and some carbon dioxide in the blood.
Catalytic	Act as enzymes that regulate biochemical reactions.
	Examples : Salivary amylase, sucrase and ATPase.

(iv) Vitamins

Historical review

N. I. Lunin (1881) discovered vitamins. The term 'vitamin' was first used by Funk in 1912. Hopkins and Funk (1912) propounded a 'vitamin theory'.

Definition: Vitamin are complex organic compounds needed daily in minute quantities and act as growth and metabolic regulatory substances.

Sources: Vitamins can only be synthesized by green plants, hence animals depend for their vitamin requirement upon the plants. Human body manufactures vitamin *D* using ultraviolet rays of sunlight and can store A, D, E, K and B₁₂. The chemical compositions of vitamins are known and it is possible to synthesize them.

Importance : The vitamins are not a sources of energy. They regulate the various metabolic processes. They mostly act as the constituents of coenzymes in the cells.

Types: Vitamins are divided into two groups -

- (a) Fat soluble vitamin: A, D, E and K.
- (b) Water soluble vitamin: B complex and C.

UNIVERSAL BOOK DEPOT 1960

Table: 5.1-10 Fat soluble vitamins

Name of vitamins and chemical formula	Discovery	Sources	Daily requirement per day	Functions	Name of Deficiency Disease	Symptoms	Other Features
Vitamin A or Retinol or anti xero-phthalmic or anti infection vitamin $C_{20}H_{29}O$	Mc- Collumn and Davis (1913)	Butter, liver oils, egg yolk, mango and orange, carrot, yellow, green vegetables.	2 mg	Part of visual pigment, maintenance of epithelia and prevention of keratinization of epithelium. Beta carotene act as Antioxidants.	Xerophthalmia Night blindness or nyctalopia Keratomalacia. Dermatosis	Drying of eyeball Unable to see in dim light Epithelium keratinised Dry scaly skin	Synthesized and stored in the liver. Destroyed by - strong light.
Vitamin D or Ergocalciferol or sunshine vitamin or anti ricket vitamin $C_{28}H_{44}O$	Steenbock and Hess 1924)	Cod liver oil, butter, fish, eggs, milk, brain, lung, and spleen.	0.01 mg	Facilitates absorption of calcium and phosphorus by intestine and their retention in body and deposition in bones.	Rickets in children Osteomalacia in adults.	Deformities of bones like bowlegs, pigeon chest Weak bones liable to easy fracture	Synthesized in the body on exposure of skin (7-hydroxy cholesterol) to light. Destroyed by – oral contraceptives
Vitamin E or α Tocopherol or anti-sterility vitamin $C_{29}H_{46}O_2$	Evan and sore (1922)	Fresh green vegetables, meat, yolk, vegetable oils, butter and cheese, peanuts wheat germs.	20 mg	Antioxidant and some role in ETS. DNA / RNA/RBC formation promote wound healing.	Anaemia Sterility Muscular atrophy	Destruction of RBC. In male causes sterility and in female abortion may occur. Effect not proved in man. Degeneration of muscles	Destroyed by UV – rays. It is also used for curing tumour and cancer
Vitamin K or Phylloquinone or anti haemorrhagic vitamin $C_{31}H_{46}O_2$	Dam and Droisy (1935)	Fresh green vegetables. tomatoes, liver, soyabean, cheese, egg.	0.07 – 0.14 mg	Synthesis of prothrombin for normal clotting of blood.	Haemorrhage	Reduced ability of blood to clot and also leads to haemorrhages.	Vitamin K is synthesised by intestinal microbes present in the intestine. Destroyed by—prolonged use of antibiotics.

Table: 5.1-11 Water soluble vitamins

Name of Vitamins and Chemical Formula	Discovery	Sources	D.R.	Function	Name of Deficiency Disease	Symptoms	Other Features
Vitamin B_1 or Thiamine or anti neuritic or antiberiberi $C_{12}H_{16}N_4SO$	C. Funk (1926)	Branrice, whole wheat flour, egg, meat, liver yeast etc.	1-1.5 mg	Act as an enzyme in cellular respiration, role in nutrition of nerve cells. Essential for carbohydrate metabolism, protein synthesis and control water balance in body. Major component of co-enzyme carboxylase.	Beri- beri or Dry beri - beri (man) Polyneuritis or wet beri – beri (animals) Cardiovascular atrophy	Loss of appetite and weight, retarded growth, muscular dystrophy. Nerves become extremely irritable. Heart enlargement	Beri-beri disease was discovered by Eijkman Destroyed by — cooking

UNIVERSAL BOOK DEPOT 1960

778 Digestion and Absorption

The second second					Committee of the second	A CONTRACTOR OF THE PROPERTY O	
Vitamin B_2 or G or yellow enzyme or Riboflavin or Lactoflavin or ovaflavin or hepatoflavin $C_{17}H_{26}N_4O_6$	Warburg and Christain	Cheese, egg, yeast, meat, liver, cereals, green, vegetable.	1-2 mg	Required for cell growth. Form pair of coenzyme (FMN, FAD).	Cheilosis Glossitis Keratitis	Cracking of skin at corners of mouth Inflammation of tongue Inflammation of skin	Stored in liver, Excess of this is eliminated in urine. It is associated with the physiology of vision
Vitamin B_3 Yeast factor or pantothenic acid or anti greying factor on chick antidermatitis factor $C_9H_{17}O_5N$	Williams (1933)	All foods, more in yeast, kidney, liver, egg, meat, milk, ground nut	5-10 mg	Part of co- enzyme A. needed for cell respiration, necessary for normal skin and nerves.	Burning feet syndrome, Nervous disorder	Nerve degeneration	It occurs in all types of plants and animal tissues. Its deficiency cause greying of hair
Vitamin B ₅ or Niacin or Nicotinic acid or pellagra preventing factor C ₆ H ₅ NO ₂	Goldberger (1912)	Fresh meat, liver, fish, milk, cereals, pulses, yeast etc.	16-20 mg	It is an essential component of NAD and NADP thus form coenzymes, metabolism of carbohydrates, functioning of gastrointestinal tract and nervous system	Pellagra, Dermatitis, Diarrhoea Dementia Death (4-D syndrome)	Rough skin Inflammation of skin which becomes scaly and papillated Dehydration Neural deterioration which may lead to madness	It is characterised by 3D's i.e. dermatitis diarrhoea and dementia Destroyed by - cooking Pellagra preventing factor Goldberger also called Goldberger's p-p factor It is also synthesized by colon bacteria
Vitamin B_6 or pyrido-xine or anti dermatitis factor $C_8H_{11}O_3N$	Gyorgyi (1928)	Brewer's yeast, liver, egg, yolk, kidney, milk, and vegetables.	2 mg	It is essential component of coenzyme pyridoxal phosphate. It promotes growth in rats used for curing tuberculosis.	Anaemia Dermatitis, paralysis & death of rats. Mental disorder Dermatitis	Nausea, lack of RBC (blood) Disturbance of central nervous system Skin leisons	Term B ₆ was coined by Gyorgy. Destroyed by – cooking and oral contraceptives
Vitamin H or B_7 or Biotin or coenzyme R $C_{10}H_{16}N_2O_3S$	Bateman and Allison (1916)	Yeast, vegetables and egg yolk	150-300 mg	It acts as coenzymes and essential for fat synthesis and energy production.	Dermatitis	Scaly and itchy skin	It is synthesized by intestinal bacteria Destroyed by — prolonged use of antibiotics
Folic Acid or Vitamin M or folacin or Anti anaemic factor	Day (1935)	Green vegetable (spinach) Banana, orange and Liver.	0.4 mg	It forms coenzymes and play essential role in cell metabolism, Necessary for erythropoiesis, required for DNA synthesis.	Megaloblastic anaemia. Sprue	Enlarged RBCs Ulceration of mouth	It is also synthesized by intestinal bacteria Destroyed by - cooking

UNIVERSAL BOOK DEPOT 1866

Vitamin B_{12} or Cyanocobalam ine or Animal protein factor (APF) or Intrinsic factor of castle $C_0H_{00}O_{14}N_{14}PCo$	Rickets (1948)	Meat, egg, liver, fish, synthesized by intestinal bacteria.	0.003 mg	Required for chromosome duplication and formation of blood corpuscles.	Pernicious anaemia	Reduced formation of erythrocytes in bone marrow	It is also known as anti pernicious factor Also synthesized by intestinal bacteria in human colon Destroyed by excessive heat
Vitamin C or Ascorbic Acid $C_6H_6O_6$	Szent Gyorgyi (1928)	Citrus fruits such as lemon, mango, amla, plumes, guava.	40-60 mg	Functions as part of oxidation-reduction system. Helps in secretion of collagen cement dentine. Helps body to develop resistance to diseases. Helps in absorption of Ca and Fe in the intestine. Wound healing.	Scurvy.	Spongy and bleeding gums, fragile blood vessels and bones.	Required by primates, all other vertebrates and some other invertebrates can synthesize vitamin C. It is the earliest known vitamin. It is wound healing vitamin. Destroyed by heating

Table: 5.1-12 Other Types of vitamins, functions and deficiency symptoms

Name of Vitamin	Function	Symptoms of deficiency
Inositol or mouse antialopecia factor	Stimulate growth of mice. Spectacle-eye condition in rat can be treated. Keep a limit on the cholesterol level in the blood of man.	Causes reduced growth and alopecia (loss of hair) in the mice. Also causes haemorrhagic degeneration of the adrenal gland.
Choline	It is an important lipotropic factor which prevent excessive development of fatty liver. It takes part in the formation of acetylcholine which is involved conduction of nerve impulse.	Chronic deficiency causes cirrhosis in the liver also causes haemorrhagic changes in kidney.
Vit.P or citrin	Control the permeability and fragility of the capillary wall to plasma protein works as the co-factor with vitamin C.	Its deficiency causes subcutaneous bleeding due to break down of capillary walls.

(vii) **Mineral elements**: They forms approximately 4% of body weight. They are essential to regulate the various metabolic activities of the animals. The various types of mineral are group

into two categories as minor element. Examples - Ca, S, P, Na etc. and trace element examples - Cu, Zn, Mn etc. Some of these minerals are described as follows -

Table: 5.1-13 Chart of important minerals required in animal bodies

Mineral elements	Sources	Significance	Effects of deficiency	
Minor elements (1) Calcium–Ca	Milk, Cereals, Cheese, Green Vegetables, Pods.	Required for formation of teeth and bones, blood clotting, functions of nerves and muscles.		
(2) Phosphorus–P	Milk, Meat, Cereals.	Required for formation of teeth and bones and acid-base balance; component of ATP, DNA, RNA.	Weak teeth and bones; retarded body growth and physiology.	
(3) Sulphur–S	Many proteins of food.	Component of many amino acids.	Disturbed protein metabolism	
(4) Potassium–K	Meat, Milk, Cereals, Fruits and Vegetables.	Required for acid-base balance; water regulation and function of nerves.	Low blood pressure, weak muscles; risk of paralysis.	
(5) Chlorine-Cl	Table Salt.	Required for acid-base balance; component of gastric juice.	Loss of appetite; muscle cramps.	
(6) Sodium-Na	Table Salt.	Required for acid-base and water balances and nervous functions.	Low blood pressure, loss of appetite; muscle cramps.	
(7) Magnesium–Mg	Cereals, Green Vegetables.	Cofactor of many enzymes of glycolysis and a number of other metabolic reactions dependent upon ATP.	Irregularities of metabolism, principally affecting nervous functions.	

(8) Iron–Fe	Meat, Eggs, Pods, Cereals, Green Vegetables.	Component of haemoglobin and cytochromes.	Anaemia weakness and weak immunity.
(9) lodine-I	Milk, Cheese, Seafood, Iodized salt.	Important component of thyroxin hormone and regulate metabolism of cell.	Goitre, cretinism.
Trace Elements (10) Fluorine–F	Drinking water, Tea, Seafood	Maintenance of bones and teeth.	Weak teeth, Larger amount causes mottling of teeth.
(11) Zinc–Zn	Cereals, Milk, Eggs, Meat, Seafood	Cofactor of digestive and many other enzymes.	Retarded growth, anaemia, rough skin, weak immunity and fertility.
(12) Copper–Cu	Meat, Dry fruits, Pods, Green Vegetables, Seafood.	Cofactor of cytochrome oxidase enzyme. Necessary for iron metabolism and development of blood vessels and connective tissues.	Anaemia, weak blood vessels and connective tissue and damage to central nervous system.
(13) Manganese–Mn	Dry fruits, cereals, Tea, Fruits and Green Vegetables.	Cofactor of some enzymes of urea synthesis and transfer of phosphate group.	Irregular growth of bones, cartilages and connective tissues.
(14) Cobalt-Co	Milk, Cheese, Meat.	Important component of vitamin B ₁₂	Anaemia.
(15) Selenium–Se	Meat, Cereals, Sea food.	Cofactor of many enzymes; assists vitamin E.	Muscular pain; weakness of cardiac muscles.
(16) Chromium–Cr	Yeast, Seafood, Meat, Some vegetables.	Important for catabolic metabolism.	Irregularities of catabolic metabolism and ATP production.
(17) Molybdenum-Mo	Cereals, Pods, Some Vegetable	Cofactor of some enzymes.	Irregular excretion of nitrogenous waste products.

Nutritional imbalances and disorders

Balanced diet: The diet which contain the various nutrients in such proportions as can satisfy all the various needs of our body, is called a "balanced diet".

Table: 5.1-14 Balanced diet for moderately active adult Indian

Name of food	Recommended amounts (gms per day)					
	Adult man	Adult woman				
(1) Cereals (Wheat/Rice)	520	440				
(2) Pulses	50	45				
(3) Milk	200	150				
(4) Meat/Fish or Egg	30	30				
(5) Fats (Oil, Butter, Ghee)	45	25				
(6) Sugar/Molasses	35	20				
(7) Root and Tubers (Raddish, Potato, etc.)	60	50				
(8) Green leafy vegetables	40	100				
(9) Other vegetables	70	40				

The proportion of carbohydrates, proteins and fats into fulfill energy requirement is 4:1:1 i.e. 65% of energy is obtained from carbohydrates and 10–20% each from proteins and fats. This amount of energy is fulfilled by intake of 400–600 gm of carbohydrates, 80–100 gm of proteins and 50–60 gm of fats. The balanced diet must also contain sufficient amount of minerals and vitamins.

Metabolic rates

- (1) **Basal metabolic rate**: Amount of energy required daily by a person to maintain its basal metabolism and is about 1600 *k* cal/day.
- (2) Routine metabolic rate : Amount of energy required daily by a person to do his routine work. It is about 2800 k cal/day for males and 2300 k cal for female.
- (3) **Active metabolic rate**: Amount of energy required daily by a person to maintain its high metabolic rate during heavy physical work and is about 4000 to 6000 k cal/day for males and 4500 k cal for females. It has been scientifically determined that a child of 4–6 years approximately requires 1500, a child of 13–15 years requires 2500 and a youth of 16–18 year requires 3000 k cal of energy per day.

Table: 5.1-15 Daily Dietary Requirements of Nutrients (Recommended by Indian Council of Medical Research)

Individual	Total kcal	Protein (gms.)	Calcium (gms.)	Iron (mgs.)	Vitamin A (μg.)	Thiamin (mgs)	Riboflavin (mgs.)	Niacin (mgs.)	Folacin (μg.)	Vitamin B ₁₂ (μg.)	Vitamin C (mgs.)	Vita min D (IU)
(1) Man Moderately active	2800	55	0.4-0.5	24	750	1.4	1.7	19	100	1	40	
(2) Woman	2200	45	0.4-0.5	32	750	1.1	1.3	15	100	1	40	1200
(i) Moderately active	2700	59	1.0	40	750	1.3	1.5	17	300	1.5	40	
(ii) Pregnant	2750	70	1.0	32	1150	1.4	1.6	19	150	1.5	80	

							Dig	gestion a	ind Abso	rption 7	81 Un	NIVERSAL DOK DEPOT 196
(3) Boy (16-18 years)	2820	53	0.5-0.6	25	750	1.4	1.7	19	100	1	40	200
(4) Girl (16-18 years)	2200	44	0.5-0.6	35	750	1.1	1.3	15	100	1	40	200

Nutritional disorders : Every organism requires an adequate supply of nutrients in proper proportion in their diet for proper growth and development. There are two types of nutritional disorders

(1) Diseases due to over nutrition

- (i) **Fluorosis**: Caused due to excess of fluorides. It results in tooth and bone decay.
- (ii) Obesity: This is over-nutritional disorder. It is caused when "energy inputs exceeds energy output". It results in deposition of excess fat in the body.
- (iii) Constipation: Slow movement of faeces down the large intestine causes accumulation of dry and hard stool is colon. It is generally caused by irregular bowel habits.

- (iv) Diarrhoea: Rapid movement of faecal matter down the large intestine causes loose stools called diarrhoea. It may be also caused by viral or bacterial infections of intestinal tract, particularly of large intestine and by nervous tension.
- (v) **Piles or haemmorhoids :** Enlargement of the anal veins. It may be either hereditary or may be caused due to rapid changes in the diet.
- (vi) Hypercholesterolemia: Caused due to excess of saturated fats like butter, ghee, hydrogenated vegetable oils and eggs etc. It results in increased level of cholesterol in blood, arteriosclerosis, coronary thrombosis, heart attack etc.
- (vii) **Hypervitaminosis** A: It results in loss of appetite, body hairs, painful swelling etc.
- (viii) **Hypervitaminosis** D : It results in deposition of calcium ion in the soft tissues of the body.

(2) Diseases due to deficiency of nutrition (malnutrition)

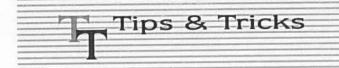

Name of the Deficiency	Deficient Nutrient	Symptoms
Anaemia (microcytic)	Fe	Haemoglobin and number of erythrocytes gets reduced.
Megaloblastic anaemia	Folic acid and B ₁₂	Presence of immature erythrocytes in blood.
Pernicious anaemia	Vitamin B ₁₂	Immature RBC without Hb. This may be fatal unless treated with vitamin B_{12} injection.
Xerophthalmia	Vitamin A	Thickened, keratinised, opaque ulcerated cornea. Prime cause of blindness in India, especially among children.
Night Blindness	Vitamin A	Less rhodopsin in rod cells of retina. So no vision in dim light.
Rickets (in children)	Vitamin D	Weak, soft, thin bones due to poor deposition of Ca and P. Bent long bones and painful swelling on wrist, elbow and knee joints.
Osteomalacia (adults)	Vitamin D	Weak bones of vertebral column, pelvis gets bent and deformed by body weight.
Sprue	Folacin	Ulceration of mouth, inflammation of bowel, indigestion, diarrhoea, weakness.
Pigeons breast	Vit. – D	Incomplete ossification at the end of limb bone, deformed ribs leading to pigeons breast.
Beri – beri	Vitamin B ₁ (Thiamine)	Reduces aerobic carbohydrate metabolism. So peripheral nerves are inflammed causing pain, numbness and weakness of limb muscles. Paralysis. Fluid accumulation in tissues or oedema of hands and legs. Cardiac oedema.
Scurvy	Vitamin C	Fragile blood vessels because of defective collagen fibres in their walls. Bleeding gums, teeth fall, bones fragile. Wound healing delayed, vitamin C is recommended in serious injury.
Bleeding disease (Hypoprothrombin anaemia)	Vitamin K	Delayed blood clotting (s) so profuse bleeding.
Marasmus	Protein / Malnutrition	Growth and replacement of tissue proteins imparted so emaciated body with thin limbs and prominent ribs, dry, thin and wrinkled skin, Diarrhoea. It affects infants under one year of age.
Kwashiorkor	Protein	Wasting muscles, thin limbs, Retarded growth of body and brain, Oedema, Diarrhoea. It commonly affects babies between 1-3 years of age.
Pellagra	Nicotinamide	Swollen lips, thick pigmented skin of hands and legs. Irritability.
Osteoporosis	Ca	Weakning of bones, tooth decay.
Goitre	I_2	Enlargement of thyroid gland.
Muscular cramps	NaCl .	Pulling of muscles due to dehydration.
Dental cramps	Fluorine	Tooth decay.

Regulation of food intake

Hunger: Hunger is defined as the intrinsic (involuntary) desire or craving for food. Hunger is associated with a number of objective sensations. For instance, food deprival for many hours causes intense rhythmic hunger contractions in stomach, which even causes intense pain (hunger pangs) send sensory impulses to a "hunger or feeding centre", located in the lateral regions of hypothalamus.

When glucose levels fall in blood, hunger centre is stimulated. Hunger centre transmits impulses to wall of stomach and wall of empty stomach start contraction or hunger pangs. After taking meal satiety centre which is located in hypothalamus stimulates and feeding is stopped. During high fever person does not feel like taking meal because high temperature shuts off the appetite centre.

Thirst: Subconscious desire for water is called thirst. It is also induced by a hypothalamic "thirst centre". When amount of water decreases in body fluids (blood, lymph, tissue fluid, cerebrospinal fluid etc.) due to fever, exercise and sweating, copious urination, diarrhoea, etc. This induces the feeling of thirst. Presumably, a fall in glucose level in the blood also induces thirst.

- Upper canine form tusk in walrus for digging mollusc and for locomotion.
- ✓ In carnivores, last premolars in upper jaw and first molars
 in lower jaw may have very sharp cusps for cracking bones and
 shearing tendons. These are called carnassial teeth.
- M Tonsillectomy Surgical removal of tonsil.
- Cheek pouches − In some rodents (squirrel, rat) certain old world monkey, the vestibule extends to form cheek pouches for temporary storage of masticated food.
- Elephant tusk is the upper incisors.
- Teeth of fishes are modified placoid scales.
- Pyorrhoea infected gums and tooth sockets.
- Maximum number of teeth present in opossum is $\frac{5134}{4134} \times 2 = 50$.
- The number of teeth that grows once and twice in humans life is 12 and 20 respectively.
- Lophodont: Cusps of premolars and molars fuse and form transverse ridges e.g. in elephant.
- ✓ Jacobson organ (Vomeronasal organs) This organ serve
 to smell food and recognize its chemical nature. They also help
 enemy recognition, locating members to opposite sex, courtship
 etc. It is found in reptiles such as lizards, snakes and sphenodon.

- ✓ Taste of chilli is not real taste but it is burning sensation of nerves.
- Fangs of poisonous snake attached to maxillary bones, they are replaceable. Solenoglyphous, Proteroglyphus and Opisthoglyphus types of fang occurs in poisonous snake.
- Greenish faecal matter passed by infant in first two days of birth due to sterilized intestine is called meconium.
- National institute of nutrition is located in Hyderabad.
- Gastritis Inflammation of stomach.
- Amount of rennin decreases with age, then the curdling of milk is done by pepsin and chymotrypsin.
- Removal of stomach causes dumping syndrome.
- Oesophagus does not secrete any enzyme
- Stomach absent in labeo, lamprey and hag fish.
- The study of alimentary canal is called Gastro-Enterology.
- ${\it E}$ Digestion of cellulose is also found in termites (white ants). In which symbiotic flagellate Triconympha found in their intestine that secretes enzyme β -glucosidase which hydrolyse the cellulose to sugars which are used by both symbionts.
- Bursa fabricious is also called cloacal thymus, is a lymphoid
 mass in the cloaca of birds. It is site of differentiation of Blymphocytes. So a part of immune system.
- ✓ Carnivores, cattles and other cud-chewing mammals lack
 ptyalin enzymes in their saliva.
- Pepsin hydrolyses the peptic bonds on c-terminus side of tyrosine, tryptophan and methionine amino acids.
- Trypsin is called universal enzyme as found from protozoans to mammals.
- Nucleases of pancreatic juice digest about 80% of nucleic
- Pancreatic juice is called as "complete digestive juice" as it is protease enzymes can break all type of peptide bonds.
- Amylases act on glycoside linkages.
- Pepsin, trypsin and chymotrypsin are endopeptidases whereas carboxy peptidase is exopeptidase.
- Blood is digested by trypsin.
- Enterokinase is a non-digestive protease while bile is a non-enzymatic digestive juice.
- Galactosemia is a disease of children in which amount of galactose increases in blood. Such children are kept on milk free diet
- Sphincter of boyden is absent in rabbit and frog.
- Liver produces biles, cholesterol and iron.
- Prussic acid formed during metabolism is rendered harmless by liver.
- Bile is alkaline in man but acidic in cats and dogs.
- Choleretic are substance which increase bile secretion from liver e.g. bile salts.

- Cholagogues are substances which causes the contraction of the gall bladder.
- S Obstructive jaundice is the condition when hepatic or common bile duct may be obstructed and failing to be excreted bile by the bile capillaries.
- World food day (W.F.D) is 16th october.
- White revolution Increased milk production.
- Blue revolution Increased fish production.
- Yellow revolution Increased oil production.
- The foul & flatus odour of the faeces is due to presence of gases such as CH₄, NH₃, H₂S, CO₂ etc. and presence of indole, skatole and mercaptones amines formed due to decarboxylation of tryptophan amino acid.
- Villus is the unit of absorption of food.
- The enzymes that converts glucose to glucose 6-phosphate is hexokinase.
- Human insulin is known as Humulin.
- Fructose is the sweetest sugar found in fruits but not in grapes.
- S Glycogen is also called as "animal starch".
- Zinc is necessary to maintain plasma concentration of vitamin A.
- Vertebrates cannot digest keratin protein of hair, nails, fibroin protein of silk fibers etc, but certain insects can digest these proteins so damages silken and woolen garments.
- Vitamin C was the first vitamin to be produced during fermentation process using wild bacteria.
- An alcoholic is always deficient of vitamin C.
- Vitamin B₁₇ is a recently discovered vitamin with anticancer property.
- Most of the B-complex vitamins are coenzymes.
- Presently vitamin B₁₂ is produced directly during the course of fermentation by propioni bacteria and certain strains of Pseudomonas.
- Vitamins, which are synthesized by the intestinal flora are vitamin K. Thiamine, Riboflavin, Pantothenic acid, Niacin, Pyridoxin, Biotin and Folic acid.
- Gama linolenic acid and arachidonic acids are essential fatty acid in mammals.
- Phenyl alanine amino acid is denoted by symbol F.
- The overdosage of vitamin 'A' causes injury to lysosomes.
- Vitamin B₆ is essential for transmission.
- Frog tadpole is delayed in metamorphosis due to less amount of iodine in water.
- The most complex amino acid having double rings structure is tryptophan.
- The intestinal bacteria are able to synthesize both essential amino acids and vitamins in ruminants.
- Mhiptail disease is caused due to the deficiency of molybdenum.

Ordinary Thinking

Objective Questions

Digestive System

In mammals the lower jaw is made up of

[MP PMT 1998; BVP 2001]

- (a) Dentary
- (b) Maxilla
- (c) Premaxilla
- (d) Palatine
- 2. Dental formula of rabbit is

[CPMT 1994, 98, 2010; Bihar CECE 1995]

- 1023 (a) 1023
- 3023 (b) 3023
- 1023 2023
- 2103 2304
- 2033 1023
- Which one has a developed canine 3.

[MP PMT 1995]

- (a) Polar bear
- (b) Walrus
- (c) Male elephant
- (d) Rhinoceros
- The hardest substance of vertebrate body is 4. INCERT: MP PMT 1995; RPMT 2006]

Or

Crown of teeth is covered by [AFMC 2005; MP PMT 2013]

- (a) Keratin
- (b) Enamel
- (c) Dentine (d) Chondrin
- 5. On the tongue of rabbit which type of papillae are present but absent in human
 - (a) Circumvallate
- (b) Circumvallate and foliate
- (c) Foliate
- (d) Fungiform
- 6. The layer lining the lumen of the human alimentary canal is [Kerala PMT 2012]
 - (a) Serosa
- (b) Sub-mucosa
- (c) Muscularis
- (e) Mucosa
- (d) Pleura
- The back flow of faecal matter in the large intestine is prevented by the presence of [NCERT; Kerala PMT 2011]
 - (a) Epiglottis
 - (b) Sphincter of Oddi
 - (c) Ileo-Caecal valve
 - (d) Gastro-oesophagal sphincter
 - (e) Pyloric sphincter
- In mammals the teeth are
 - Of different types
 - (ii) Embedded in the cup-like socket of the jaw bones
 - (iii) Only two sets, present throughout life

These conditions are referred as

[Kerala PMT 2007, 09; Odisha JEE 2009] Or

Teeth of rabbits are

[CPMT 2004]

- (a) Heterodont, the codont and diphyodont
- (b) Thecodont, heterodont and diphyodont
- (c) Diphyodont, thecodont and heterodont
- (d) Heterodont, diphyodont and thecodont
- (e) Thecodont, diphyodont and heterodont
- It is a correct dental formula for the child falling under age group 5-6 yrs. [GUJCET 2007, 09] (a) I2/2, C1/1, P M2/2, M0/0 (b) I2/2, C1/1, P M2/2, M3/3

 - (c) I1/1, C2/2, P M2/2, M3/3 (d) I2/2, C2/2, P M1/1, M3/3

- The mucosal layer in the stomach form irregular folds known as [NCERT; Kerala PMT 2011]
 - (a) Villi

(b) Lumen

- (c) Rugae
- (d) Crypts of Lieberkuhn
- (e) Lacteals
- A pair of small lymphatic tissue present at the sides of root tongue is called as [CBSE PMT 1993]
 - (a) Thyroid

(b) Tonsils

- (c) Epiglottis
- (d) Adenoids
- 12. Vomerine teeth are present in
 - (a) Man
- (b) Reptiles
- (c) Frogs
- (d) Rabbits
- 13. The function of tongue is to

[CBSE PMT 1993]

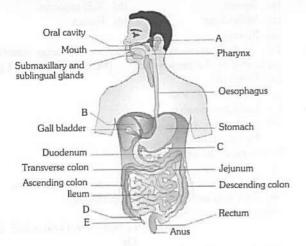

- (a) Help in the act of swallowing
- (b) Help in mixing saliva with the food
- (c) Help in speaking
- (d) All the above
- The primary dentition in human differs from permanent dentition is not having one of the following type of teeth

[AIPMT 2015]

O

A baby boy aged two years is admitted to play school and passes through a dental check-up. The dentist observed that boy had twenty teeth. Which teeth were absent [NEET 2017]

- (a) Premolars
- (b) Molars
- (c) Incisors
- (d) Canine
- 15. Taste buds for bitter taste are found on tongue at
 - (a) Tip
- (b) On basal surface
- (c) Posterior part
- (d) Lateral sides
- 16. The given figure shows the human digestive system. Identify A, B, C, D and E respectively [NCERT]

- (a) A Parotid gland, B Liver, C Caecum, D Pancreas, E - Vermiform appendix
- (b) A Parotid gland, B Caecum, C Pancreas, D Liver,
- E Vermiform appendix
 (c) A Parotid gland, B Pancreas, C Liver, D Caecum,
 E Vermiform appendix
- (d) A Parotid gland, B Liver, C Pancreas, D Caecum, E - Vermiform appendix

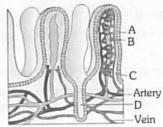

- 17. Two friends are eating together on a dining table. One of them suddenly starts coughing while swallowing some food. This coughing would have been due to improper movement of [NCERT; CBSE PMT (Pre.) 2011]
 - (a) Tongue

(b) Epiglottis

- (c) Diaphragm
- (d) Neck
- If for some reason our goblet cells are non-functional, this will adversely affect [CBSE PMT (Pre.) 2010]
 - (a) Smooth movement of food down the intestine
 - (b) Production of somatostatin
 - (c) Secretion of sebum from the sebaceous glands
 - (d) Maturation of sperms
- In mammals, the digestion of starch starts from [NCERT;
 CPMT 1995; BHU 2001; MHCET 2003; BCECE 2006]
 - (a) Mouth
- (b) Stomach
- (c) Oesophagus
- (d) Duodenum
- If the dental formula of Rabbit is 2033/1023. What does it show [CPMT 1993; Manipal 1995; RPMT 2001]
 - (a) Total number of teeth in Rabbit is 15
 - (b) Number of total incisors in Rabbit is 3
 - (c) Diastema is present between incisors & premolars
 - (d) In the formula 2033 is for adult and 1023 is for young ones
- 21. Which of the following teeth are lophodont

[CPMT 1998; AIIMS 2002]

- (a) Incisor and canine
- (b) Premolar and molar
- (c) Canine and premolar
- (d) Premolar and incisor
- 22. The given figure shows a section of small intestinal mucosa showing villi. Identify A to D [NCERT]

- (a) A Crypts, B Lacteal, C Capillaries, D Villi
- (b) A Villi, B Lacteal, C Crypts, D Capillaries
- (c) A Lacteal, B Villi, C Capillaries, D Crypts
- (d) A Villi, B Lacteal, C Capillaries, D Crypts
- 23. Tusk of an elephant is an enormously enlarged

[AFMC 2000; HP PMT 2005; Odisha JEE 2010]

- (a) Upper canine
- (b) Lower incisor
- (c) Upper incisor
- (d) Lower canine
- The type of muscle fibre present in the wall of alimentary canal is [Odisha JEE 2010]
 - (a) Smooth muscle fibre
- (b) Striped muscle fibre
- (c) Cardiac muscle fibre
- (d) Both (a) and (b)
- 25. Which of the following is vestigial teeth found in human

[Pb. PMT 2000]

- (a) Incisors
- (b) Premolars
- (c) Diphyodont
- (d) Wisdom tooth

26.	Teeth	in	frog	are
20.	reem	ш	HOG	ar

[BHU 2002]

- (a) Acrodont
- (b) Homodont
- (c) Polyphyodont
- (d) All of these
- Pulp cavity of teeth is lined by [RPMT 2000, 06; CPMT 2002] 27.
 - (a) Odontoblast
- (b) Chondroblast
- (c) Osteoblast
- (d) Amyloblast
- 28. Lacteals are central lymph vessels which are found in

[NCERT; CPMT 1996]

- (a) Liver
- (b) Pancreas
- (c) Villi
- (d) Spleen
- 29. In the wall of alimentary canal which are/ is true sequence from outer to inner [NCERT; BHU 2003]
 - (a) Serosa, longitudinal muscle, mucosa, sub mucosa
 - (b) Mucosa, serosa, long muscle
 - (c) Serosa, long muscle, circular, sub-mucosa, mucosa
 - (d) Serosa, long muscle, sub-mucosa, mucosa
- 30. Dental formula of human being is

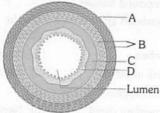

[NCERT:

Manipal 1995; MP PMT 2001, 03, 11; Odisha JEE 2004; BCECE 2005; DPMT 20061

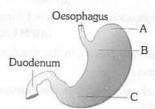

- (a) I_2, C_2, P_1, M_3
- (b) I_2, C_1, P_2, M_3
- (c) I_3, C_1, P_2, M_2
- (d) I_2, C_2, P_3, M_1
- 31. Some of the animals eat their feaces to digest the cellulose contents again, such animals are known as

[DPMT 2003; Odisha JEE 2004]

- (a) Sanguivorous
- (b) Frugivorous
- (c) Coprophagous
- (d) Deteritivorous
- The given diagram indicates the TS of Gut. Identify A, B, C 32. and D [NCERT]

- (a) A Serosa; B Submucosa; C Muscularis; D Mucosa
- (b) A Serosa; B Muscularis; C Mucosa; D Submucosa
- (c) A Muscularis; B Serosa; C Submucosa; D Mucosa
- (d) A Serosa; B Muscularis; C Submucosa; D Mucosa
- 33. The given diagram represent anatomical regions of human stomach. Identify A, B and C [NCERT]

- (a) A Pyloric; B Fundus; C Cardiac
- (b) A Fundus; B Cardiac; C Pyloric
- (c) A Cardiac; B Fundus; C Pyloric
- (d) A Fundus; B Pyloric; C Cardiac

- The muscular contraction in the alimentary canal is known 34. [NCERT; MP PMT 1994; RPMT 1999]
 - (a) Systole
- (b) Diastole
- (c) Peristalsis
- (d) Metachronal
- 35. Fundic part of stomach is
 - (a) Present in rabbit but absent in frog
 - (b) Absent in rabbit but present in frog
 - (c) Absent in both rabbit and frog
 - (d) Present in both rabbit and frog
- HCl is secreted by 36.
 - INCERT: MP PMT 1999, 2009; AFMC 2005; DPMT 2006; WB JEE 2010; Odisha JEE 2011; PET (Pharmacy) 2013]
 - (a) Zymogen cells
- (b) Oxyntic cells
- (c) Kupffer cells
- (d) Mucous cells
- 37.
- "Chief cells" or "Zymogen cells" secrete the enzymes of the gastric juice, are found in the [CBSE PMT 1992]
 - (a) Isthmus of the gland
 - (b) Neck of the tubular gland
 - (c) Base of the tubular region
 - (d) All the above
- Inner lining of gut, stomach and liver is composed of 38.

[AFMC 1997]

- (a) Simple squamous epithelium
- (b) Simple columnar epithelium
- (c) Simple cuboidal epithelium
- (d) Compound epithelium
- The mucosal lining of the oesophagus of mammals is made up of [MP PMT 1997]
 - (a) Simple columnar epithelium
 - (b) Squamous epithelium
 - (c) Stratified cuboidal epithelium
 - (d) Stratified columnar epithelium
- 40. Submucosa is thickest in

[MP PMT 1998]

- (a) Stomach
- (b) Oesophagus
- (c) Intestine
- (d) Rectum
- 41. Which one of the following is the correct pairing of the site of action and the substrate of rennin [CBSE PMT 1994]
 - (a) Stomach-Casein
 - (b) Stomach-Fat
 - (c) Small intestine-Protein
 - (d) Mouth-Starch
- The site of protein digestion is

INCERT:

KCET 1994; MP PMT 2012]

A rabbit eats a lot of gram. Then its digestion starts in

[RPMT 2001]

- (a) Gullet
- (b) Stomach
- (c) Small intestine
- (d) Oral cavity
- 43. The stomach of ruminants is mainly divided into four parts, but in camel which one part is missing
 - (a) Abomasum
- (b) Omasum
- (c) Recticulum
- (d) Rumen

44.	Match	column	I	with	column	II	and	choose	the	correct
	option									

	Column I		Column II
A.	Goblet cells	1.	Antibacterial agent
B.	Lysozyme	2.	Mucus
C.	Saliva	3.	HCI
D.	Oxyntic cells	4.	Sublingual gland

[NCERT; MP PMT 2000; Kerala PMT 2010]

- (a) A-3, B-1, C-4, D-2
- (b) A-1, B-3, C-4, D-2
- (c) A-2, B-3, C-1, D-4
- (d) A-4, B-1, C-2, D-3
- (e) A-2, B-1, C-4, D-3
- During chain elongation peptide bond is formed between 45. carboxyl group of 1st amino acid and amino group of 2nd amino acid by [Odisha JEE 2010]
 - (a) Aminoacyl transferase
- (b) Aminoacyl synthetase

(d) Chloramphenicol

- (c) Peptidyl transferase
- [MP PMT 1996; Pb. PMT 2004]
- 46. Peyer's patches contain
- (a) Mucus
- (b) Sebum
- (c) Lymphocytes
- (d) Red blood cells
- Narrower distal end of stomach is called

[NCERT; MP PMT 1994, 95]

- (a) Cardiac
- (b) Duodenum
- (c) Pharunx
- (d) Pylorus
- Aggreagates of lymphoid tissue present in the distal portion 48. [DUMET 2010] of the small intestine are known as
 - (a) Villi
- (b) Peyer's patches
- (c) Rugae
- (d) Choroid plexus
- Wisdom teeths are 49.
- [AFMC 2005] (b) Last premolars
- (a) Last molars (c) Incisors
- (d) Canines
- Peyer's patches are found on the ileum in [CBSE PMT 1993] 50.
 - (a) Fishes
- (b) Reptiles
- (c) Birds
- (d) Mammals
- Water is largely absorbed in
- [NCERT; CPMT 1999, 2005]
- (a) Stomach
- (b) Oesophagus
- (c) Small intestine
- (d) Colon (Large Intestine)
- Crypts of Lieberkuhn are found in between the villi. They 52. [MP PMT 2003, 06] secrete
 - (a) Glucagon
- (b) Succus entericus
- (c) Insulin
- (d) None
- Both the crown and root of a tooth is covered by a layer of [J & K CET 2005] bony hard substance called
 - (a) Enamel
- (b) Dentine
- (c) Bony socket
- (d) Cementum
- Which of the following nerves innervates alimentary canal 54.

[Odisha JEE 2010]

- (a) Oculomotor
- (b) Abducens (d) Vagus
- (c) Trigeminal Goblet cells are 55.
- [NCERT; MP PMT 2012]
- (a) Unicellular mucous gland
 - (b) Multicellular mucous gland of stomach
 - (c) Tubula-veolar gland
 - (d) All of the above

Which of the following is correct regarding diastema

[Odisha JEE 2010]

- (a) Gap between bones
- (b) Gap between the teeth/Absence of certain teeth
- Gap between nerves (c)
- (d) Gap between cells
- Brunner's gland are found in which of the following layers 57.

[NCERT; CBSE PMT 1992, 99; CPMT 1993, 99; MP PMT 1998, 2001, 03; AFMC 2003, 08, 10;

BHU 2012; WB JEE 2012, 16]

- (a) Submucosa of stomach
- (b) Mucosa of ileum
- (c) Submucosa of duodenum (intestine)
- (d) Mucosa of oesophagus
- Pepsinogen is secreted by

[NCERT; CPMT 1993; MP PMT 2003; DPMT 2007]

- (a) Chief cells
- (b) Parietal cells
- (c) Gastric glands
- (d) Intestinal cells
- Intestinal villi are mainly concerned with 59.

[MP PMT 1994; MHCET 2001]

Or

The process by which digested food of the alimentary canal passes through its mucous membrane into circulatory system [AIIMS 1992] is called as

- (a) Assimilation
- (b) Secretion
- (c) Ultrafilteration
- (d) Absorption
- Crypt of Lieberkuhn is example for
- [Kerala CET 2003]
 - (a) Simple tubular gland
 - (b) Coiled tubular gland
 - (c) Compound alveolar gland
 - (d) Compound tubular gland
- Brush bordered epithelium is found in 61.
 - [CPMT 1999; JIPMER 2001]
 - (a) Trachea
- (b) Stomach
- (c) Small intestine
- (d) Fallopian tube
- Vermiform appendix is a part of
- [MP PMT 1994, 95]
 - (a) Alimentary canal (c) Vascular system
- (b) Nervous system
- (d) Reproductive system

Digestive glands

- How many kinds of cells are found in islet of Langerhans
 - [MP PMT 1997]

- (a) 1 (c) 3
- (b) 2 (d) 4
- 2. Which of the following statement is not correct

[AIPMT (Cancelled) 2015]

- (a) Goblet cells are present in the mucosa of intestine and secrete mucus
- (b) Oxyntic cells are present in the mucosa of stomach and secrete HCl
- (c) Acini are present in the pancreas and secrete carboxypeptidase
- (d) Brunner's glands are present in the submucosa of stomach and secrete pepsinogen

Digestion and Absorption 787 UNIVERSAL BOOK DEPOT 1960 Fat digestion is facilitated by [CPMT 1998] The pH of amylase present in saliva is 16. (a) Bile juice (b) Pancreatic juice [NCERT; CPMT 1996] (c) Gastric juice (d) None of these (b) 6.8 4. The predominant antibody in saliva is [DUMET 2010] (c) 7.2 (d) 8 (a) IgG (b) IgA 17. Characteristic of mammalian liver is [AFMC 2006] (c) IqM (d) IgD (a) Kupffer's cells and leucocytes 5. In man, Glisson's capsule is associated with the (b) Leucocytes and canaliculae [Kerala PMT 2012] (c) Glisson's capsules and Kupffer cells (a) Digestive system (b) Excretory system (d) Glisson's capsules and leucocytes (c) Nervous system (d) Reproductive system 18. The pH of succus entericus is (e) Endocrine system Parotid salivary gland are present [NCERT; MP PMT 1993] Or 6. In intenstine, pH value is (a) Below the tongue (a) 7.6 (b) Below the ear (b) 6.6 (c) Below the eye orbit (c) 5.6 (d) 2.0 (d) In the angle between two jaws 19. Succus entericus is the name given to [NCERT] Pissiform cells loaded with zymogen granules can be seen in 7. (a) Junction between ileum and large intestine [MP PMT 1993] (b) Intestinal juice (a) Liver (b) Pancreas (c) Swelling in the gut (c) Ovary (d) Kidney (d) Appendix 8. Pancreatic juice contains [NCERT] 20. Liver of rabbit is made up of (a) Trypsin, lipase and maltase (a) 4 lobes (b) 6 lobes (b) Pepsin, trypsin and maltase (c) 5 lobes (c) Trypsin, chymotrypsin, amylase and lipase (d) 7 lobes 21. Which of the following statements is correct (d) Trypsin, pepsin and amulase [CPMT 2010] Gastric juice of infants contains (a) Argentaffin cells produce serotonin [AIPMT (Cancelled) 2015] (a) Nuclease, pepsinogen, lipase (b) Villikinin is secreted by large intestine (b) Pepsinogen, lipase, rennin (c) In cheilosis, deficiency nutrient is nicotinamide (d) Bleeding diseases occur due to deficiency of vitamin E (c) Amylase, rennin, pepsinogen Which of the following is the symptom of Ulcerative colitis (d) Maltase, pepsinogen, rennin 10. Ptyalin is [AFMC 1996] [GUJCET 2015] (a) Watery stools containing blood and mucus (a) Strongly acidic (b) Slightly acidic (c) Slightly neutral (b) Difficulty in swallowing (d) Strongly alkaline 11. Liver in our body stores (c) Loss of appetite [AIIMS 1999] (a) Vitamin A (b) Vitamin D (d) Eyes turn yellow (c) Vitamin B₁₂ (d) All of these Which one of the following is not the reason for very high 23. 12. Argentaffin cells are found in load of bilirubin in a newborn INCERT: BHU 1999; AMU (Med.) 2012] (a) Excessive red blood corpuscles in the newborn burst, (a) Pancreas (b) Internal ear releasing the bilirubin (c) Gastric glands (d) Liver (b) The liver of the newborn is too young to cope up with 13. pH of gastric juice is [Odisha JEE 2008; MP PMT 2010] the heavy load of bilirubin (a) 2 (b) 4 (c) Mother's milk contain a high amount of bilirubin (c) 6 (d) Which of the 14. (d) Insoluble bilirubin in the intestine is reabsorbed by the following guards the opening hepatopancreatic duct into the duodenum blood [NEET (Phase-I) 2016] 24. Saliva is secreted from [NCERT; MP PMT 1998] (a) Semilunar valve (b) Ileocaecal valve (a) Submaxillary and sublingual glands (c) Pyloric sphincter (d) Sphincter of Oddi (b) Gastric gland In pancreas, pancreatic juice and hormones are secreted by (c) Pancreas [CBSE PMT 1990] (d) Gall bladder (a) Same cells The number of salivary glands in man is 25. (b) Different cells [NCERT] (c) Same cells at different times (a) Two pairs (b) Three pairs (d) None of these (c) Four pairs (d) Five pairs

г	UNIVERSAL

26.	Ptvalin	is an	enzyme	of

[CMC Vellore 1992; MP PMT 1994, 99; CPMT 2003: MH CET 2004; Odisha JEE 2011]

- (a) Salivary juice
- (b) Pancreatic juice
- (c) Intestinal juice
- (d) None of these
- 27. The enzymes responsible for the digestion of starch in food of man is present in
 - (a) The salivary and gastric secretions
 - (b) The salivary and pancreatic secretions
 - (c) The gastric and pancreatic secretions
 - (d) The gastric and duodenal secretions
- A lubricant, mucin in saliva is made up of [Pb. PMT 2004] 28.
 - (a) Glycoprotein
- (b) Polysaccharides
- (c) Phospholipids
- (d) Myosin
- The toxic substance are detoxicated in the human body by 29. [AIIMS 2001]
 - (a) Lungs
- (b) Kidneys
- (c) Liver
- (d) Stomach
- The trypsin enzyme is secreted by 30.

[AFMC 2003]

- (a) Stomach
- (b) Duodenum
- (c) Pancreas
- (d) Liver
- Bilirubin and biliverdin are found in[NCERT; MP PMT 2001] 31.
 - (a) Blood
- (b) Bile
- (c) Pancreatic juice
- (d) Saliva
- Match the names of glands listed under column-I with the 32. location given under column-II, choose the answer which gives correct combination of the alphabets of the two

C	Column-I (glands)	C	column –II (location)
A.	Crypts of Lieberkuhn	p.	Loop of duodenum
B.	Pancreas	q.	Stomach
C.	Adrenal gland	r.	Intestine
D.	Gastric gland	S.	Kidney

[KCET 2001; Kerala PMT 2008]

- (a) A = r, B = p, C = q, D = s
- (b) A = r, B = p, C = s, D = q
- (c) A = q, B = s, C = r, D = p
- (d) A = p, B = r, C = s, D = q
- The bile secreted by the liver cells passes into the gall 33. [NCERT; DPMT 1993] bladder through
 - (a) Hepato-pancreatic duct (b) Cystic duct

 - (c) Hepatic duct (d) Hepato-gall duct
- Which of the following is not a human salivary gland 34.

INCERT; AIIMS 1993]

- (a) Parotid
- (b) Submaxillary
- (c) Sublingual
- (d) Infra-orbital
- Which is correct about the bile of rabbit

[NCERT; RPMT 2002]

- (a) It is synthesized by gall bladder & also stored there
- (b) It is an enzyme which emulsify the fats
- (c) It contain bile salts & bile pigments
- (d) Bilirubin present in it decomposed fats

- Which of the following digestive juices have the minimum [AIIMS 2002] pH
 - (a) Bile
- (b) Saliva
- (c) Gastric juice
- (d) Pancreatic juice
- In which of the following, putrefying bacteria is present 37.

[BHU 2006]

- (a) Intestine
- (b) Colon
- (c) Stomach
- (d) Liver
- The glucose is converted into glycogen in liver and stored in 38. [MP PMT 1994, 95; CPMT 1995]
 - (a) Liver
- (b) Liver and muscles
- (c) Liver and spleen
- (d) Spleen and muscles
- Gastric juice contains 39.
- INCERT:
- CPMT 1993; Kerala PMT 2010; MP PMT 2011]
- (a) Pepsin, rennin, lipase (b) Pepsin, amylase, rennin
- (c) Pepsin, amylase, trypsin (d) Lipase, rennin, trypsin
- Enzyme arginase is found in
- [CPMT 1994]
- (a) Mouth cavity
- (b) Stomach
- (c) Intestine
- (d) Liver
- A your infant may be feeding entirely on mother's milk which is white in colour but the stools which the infant passes out is quite yellowish. What is this yellow colour due [CBSE PMT 2009] to
 - (a) Intestinal juice
 - (b) Bile pigments passed through bile
 - (c) Undigested milk protein casein
 - (d) Pancreatic juice poured into duodenum
- Kupffer cells of liver are [JIPMER 2001; MP PMT 2001, 02; 42. BVP 2002; CPMT 2003; BHU 2008; WB JEE 2011]
 - (a) Loose connective tissue (b) Phagocytic cell
 - (c) Mast cell
- (d) Fat cell
- Bile secretion is proportional to the concentration of 43. [MP PMT 2007]
 - (a) Protein
- (b) Fat
- (c) Carbohydrate
- (d) None of these
- The special feature of bile juice is that it 44.

[NCERT; Odisha JEE 2011]

- (a) Has no enzyme
- (b) Has amylase
- (c) Contains lipase
- (d) Contains H₂O
- Cells of the liver manufacture 45 (a) Diastase
- (b) Amylase
- (c) Lipase
- (d) Insulin
- Succus entericus is secreted by 46.
- [KCET 2007, 10]

[DPMT 1993]

- (a) Islets of Langerhans
 - (b) Gastric gland
 - (c) Uterine crypt and endometrium
 - (d) Crypts of Leiberkuhn and Brunner's gland
- In which of the following proteins are absent [MP PMT 2000]
 - (a) Pancreatic juice
- (b) Saliva
- (c) Bile
- (d) Intestinal juice

The same		ROLL MARKET TO SERVICE
6.	Which enzymes are likely to act on the baked potatoes eater by a man, starting from the mouth and as it moves down the alimentary canal [NEET (Karnataka) 2013	(a) Lymph capillaries (b) Blood capillaries
	(a) Pancreatic amylase → salivary amylase → lipases	(c) Repaire portai vein (d) None of these
		15. One of the following movements in our body is not
		completely involuntary. Identify it [KCET 2012]
	(c) Salivary amylase → pancreatic amylase → disaccharidases	(a) Deglutition (b) Peristalsis
- 0.0	(d) Salivary maltase → carboxy peptidase → trypsinogen	(c) Systole of the ventricles (d) Dilation of pupil of the eye
7.	Trypsin is a digestive enzyme which occurs in mammals and digests [CPMT 1992, 93; MP PMT 1995]	
	(a) Starch in buccal cavity in an alkaline medium	[NCERT; AMU (Med.) 2012]
	(b) Protein in stomach in an acidic medium	(a) Lamina propria and muscularis mucosa
	(c) Protein in duodenum in an acidic medium	(b) Submucosa and muscularis externa
	(d) Protein in duodenum in an alkaline medium	(c) Submucosa and mucosa
8.	The major site of protein breakdown to form free amin acids, is in the [WB JEE 2009]	
	(a) Kidney (b) Spleen	17. Enthusined lat is digested by
	(c) Liver (d) Bone-marrow	Bile salts act as activator of which enzyme [WB JEE 2010]
9.	The first phase in the breakdown of glucose in animal cell is	
	[CBSE PMT 1994	
	(a) Glycolysis (b) Electron transport system	(c) blie saits (d) blie pignients
	(c) Fermentation (d) Kreb's cycle	16. Lactedis are found in [NCERT; MF FMT 1999, NCET 2004]
10.	Digestion of both starch and protein is done by	(a) Liver (b) Lungs
10.	[NCERT; AFMC 1996	(c) Kidney (d) Villus of intestine
	(a) Gastric juice (b) Gastric lipase	19. Which one of the following is the correct matching of the site
	(c) Pancreatic juice (d) Ptylin	of action on the given substrate, the enzyme acting upon it and the end product [NCERT; CBSE PMT 2008]
11.	The end product of carbohydrate metabolism is	(a) Small intestine: Proteins Pepsin Amino acids
	[AFMC 1993	(b) Stomach: Fats Lipase micelles
	(a) CO_2 and H_2O (b) NH_3 and CO_2 (c) NH_3 and H_2O (d) CO_2	(c) Duodenum: Triglycerides Trypsin monoglycerides
12.	Which one of the following statements about glycogen	de (Maltaca)
	Ecologic Control of the Control of t	on it f
	(a) It is a disaccharide stored in liver which can react with ammonia to form proteins	become partially non-functional, what is likely to happen
	(b) It is synthesised in the liver and takes part in the formation of bile and lipase, besides being a source of	e
	energy	(b) The pH of stornach will fall abruptly
	(c) It is a polysaccharide which is synthesised and stored liver cells	(c) Steapsin will be more effective
	(d) It is synthesised in blood and stored in liver and muscle to provide glucose in times of need (d) It is synthesised in blood and stored in liver and muscle to provide glucose in times of need	(d) Proteins will not be adequately hydrolysed by pepsin into proteoses and peptones
10		at tines for the consequence
13.	Which one of the following statements is true regarding digestion and absorption of food in humans	[Odisha JEE 2012]
	[CBSE PMT 2009	(c) α – Destrins (d) Pensin
	 (a) Oxyntic cells in our stomach secrete the proenzym pepsinogen 	22. Most digestion and absorption of food takes place in [NCERT; Odisha JEE 2009]
	(b) Fructose and amino acids are absorded through intestinal mucosa with the help of carrier ions like Na ⁺	h (a) Stomach (b) Small intestine
	(c) Chylomicrons are small lipoprotein particles that a	e (c) Large intestine (d) Caecum
	transported from intestine into blood capillaries	 Essentially the tword 'digestion' means[NCERT; CPMT 2005]
	(d) About 60% of starch is hydrolysed by salivary amyla- in our mouth	(a) Burning of food (b) Oxidation of food (c) Hydrolysis of food (d) Breakdown of food

		The second secon				

- Some proteolytic enzymes are [NCERT; Odisha JEE 2010]
 - (a) Trypsin, Erepsin, pepsin
 - (b) Amylopsin, steapsin, ptyalin
 - (c) Amylase, lipase, zymase
 - (d) Urease, zymase, dehydrogenase
- 29 Choose the wrong statement [Kerala PMT 2012]
 - (a) Lipases and nucleases are not present in pancreatic juice
 - (b) Goblet cells secrete mucus
 - (c) Brunner's glands are sub-mucosal glands
 - (d) Carboxypeptidase catalyses conversion of proteins, peptones and proteoses to dipeptides
 - (e) Bile contains no enzymes
- 30. Rennin acts on milk proteins and converts [JIPMER 2002]
 - (a) Caseinogen into casein
 - (b) Casein into paracasein
 - (c) Caseinogen into paracasein
 - (d) Paracasein into caseinogen

31. Lacteals are associated with

[DPMT 1993; MP PMT 2013]

- (a) Secretion of lactic acid
- (b) Absorption of long chain fatty acids
- (c) Absorption of short chain fatty acids
- (d) Production of lymph
- 32. In gluconeogenesis [Pb. PMT 2000; DPMT 2003]
 - (a) Glucose is polymerized into glycogen
 - (b) Glycogen is broken into glucose
 - (c) Carbohydrates are synthesized from amino acids/lipids
 - (d) Glucose is broken into pyruvic acid
- Carrier ions like Na+ facilitate the absorption of substances 33. like [CBSE PMT (Pre.) 2010]
 - (a) Fructose and some amino acids
 - (b) Amino acids and glucose
 - (c) Glucose and fatty acids
 - (d) Fatty acids and glycerol
- The pH of the digestive juices within the human small intestine is between 7.5 and 8.5. This environment is slightly [AIIMS 2009]
 - (a) Basic

(b) Acidic

(c) Neutral

- (d) None of these
- Trypsin differs from pepsin in that (a) It digest protein in alkaline medium while pepsin does
 - so in acidic medium
 - (b) It digest protein in acidic medium while pepsin does so in alkaline medium
 - (c) Both (a) and (b)
 - (d) None of these
- Digestion of starch takes place in [NCERT; Kerala CET 2003]
 - (a) Stomach and duodenum
 - (b) Buccal cavity and duodenum
 - (c) Buccal cavity and oesophagus
 - (d) Duodenum only
- Ptyalin is inactivated by a component of gastric juice known [WB JEE 2011]
 - (a) Pepsin
- (b) Mucus
- (c) Rennin
- (d) HCI
- 38. Function of HCl in stomach is to

[MP PMT 1994; CPMT 1995; Odisha JEE 2012]

- (a) Kill micro-organisms of food
- (b) Facilitate absorption of food
- (c) Dissolve enzumes
- (d) Activate pepsinogen to pepsin
- 39 Lipids, which can be found in oil based salad dressings and ice cream, during digestion are splitted into

[NCERT; AIIMS 2009]

Or

The main function of Lacteals in the human small intestine is the absorption of [KCET 2006]

- (a) Fatty acids and glycerol (b) Glycerol and amino acids
- (c) Glucose and fatty acids (d) Glucose and amino acids
- In horses, rabbits, hares, the cellulose gets digested in the

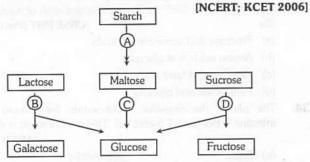

[CPMT 1994, 95, 2010:

MP PMT 2000; AFMC 2005; RPMT 2006]

- (a) Caecum
- (b) Stomach
- (c) Appendix
- (d) Rumen

- 41. Part of the stomach which opens into the duodenum [NCERT; BHU 2008; Odisha JEE 2010]
 - (a) Cardiac
- (b) Pyloric
- (c) Fundus
- (d) Body
- Energy released by carbohydrate, fats, protein is
 - (a) 4.1, 9.45, 5.65
- [NCERT: DPMT 2006] (b) 4.1, 5.65, 9.40
- (c) 5.4, 6.5, 8.9
- (d) 5.0, 7.8, 10.5
- The following is a scheme showing the fate of carbohydrates 43. during digestion in the human alimentary canal. Identify the enzymes acting at stages indicated as A, B, C and D. Choose the correct option from those given

- (a) A= amylase, B=maltase, C= lactase, D= invertase
- (b) A= amylase, B= maltase, C= invertase, D= lactase
- (c) A= amylase, B= invertase, C= maltase, D= lactase
- (d) A= amylase, B= lactase, C= maltase, D= invertase
- The food that enters intestine from stomach is called

[NCERT; AFMC 2008, 09]

- (a) Chyle
- (b) Chyme
- (c) Fundus
- (d) None of these
- End products of protein hydrolysis are 45.

[RPMT 2002; HPMT 2005]

- (a) Mixture of amino acids
- (b) Sugars
- (c) Peptides
- (d) 25 amino acids
- The amount of bile released in proportion to the amount of 46. [CPMT 2004]
 - (a) Fat in meal
- (b) Protein in meal
- (c) Carbohydrate in meal
- (d) All of the above
- Which one of the following is the matching pair of digestive 47. enzyme and substrate [MP PMT 1992]
 - (a) Rennin-Protein
- (b) Amylase-Lactose
- (c) Trypsin-Starch
- (d) Invertase-Maltose
- Digestion of which component of the food is likely to be 48. most adversely affected if the pH of stomach is made neutral [MP PMT 1992]
 - (a) Sucrose
- (b) Starch
- (c) Protein
- (d) Fat
- In man cellulose is digested in 49.

[CBSE PMT 1992; CPMT 1995]

- (a) The caecum
- (b) The colon
- (c) The appendix
- (d) Not digested at all
- Milk protein is acted upon by a gastric enzyme 50.

[NCERT;

CBSE PMT 2000; AIIMS 2002; BCECE 2005] Or

Which one of the following enzyme carries on the initial step in the digestion of milk in humans

[CBSE PMT (Pre.) 2011; CBSE PMT 2014]

- (a) Casein
- (b) Rennin
- (c) Pepsin
- (d) Caseinogen

Bile salt 51.

- [AMU (Med.) 2005]
- (a) Acts as emulsifying agent
- (b) Helps in absorption of fatty acids, cholesterol etc.
- (c) Stimulates the bile production in liver
- (d) All of the above
- Maltase converts

convert

[Odisha JEE 2005]

[WB JEE 2016]

- (a) Maltose to glucose at pH greater than 7
- (b) Maltose to glucose at pH less than 7
- (c) Maltose to alcohol
- (d) Starch to maltose at higher pH than 7
- Duodenum has characteristic Brunner's glands which secrete 53. [CBSE PMT 2004, 05; KCET 2012] two hormones called
 - (a) Prolactin, parathormone (b) Estradiol, progesterone
- (d) Secretin, cholecystokinin Kinase, estrogen The function of erepsin in the process of digestion is to 54.
 - (a) Fats into amino acids
 - Proteins in amino acids
 - Polysaccharides into disaccharides
 - (d) Disaccharides into monosaccharides
- Just as hydrochloric acid is to pepsinogen, so is
 - [MP PMT 2004]
 - (a) Enterokinase to trypsinogen
 - (b) Haemoglobin to oxygen
 - (c) Bile juice to fat
 - (d) Glucagon to glycogen
- In ileum which of the following is absorbed [CPMT 2009]
 - (a) Vitamin K
- (b) Bile salt
- (c) Glucose
- (d) Fat
- Bile salts are poured into the alimentary canal where they 57. are necessary for the absorption of
 - (a) Na+ and Ca++
 - (b) Fat soluble vitamins
 - (c) Amino acids and monosaccharides
 - (d) All the nutrients contained in chyme
- Fatty substances are emulsified by 58.
 - - (a) Lipase enzyme
 - (b) Bilirubin and biliverdin
 - (c) HCI
 - (d) Sodium salts of glycocholic and taurocholic acids
- Which of the following option best represents the enzyme **INEET 2017**] composition of pancreatic juice
 - (a) Amylase, peptidase, trypsinogen, rennin
 - Amylase, pepsin, trypsinogen, maltase
 - (c) Peptidase, amylase, pepsin, rennin
 - (d) Lipase, amylase, trypsinogen, procarboxypeptidase

Gastro intestinal hormones/Digestive enzymes

- What will happen if the secretion of parietal cells of gastric glands is blocked with an inhibitor [CBSE PMT 2008]
 - (a) In the absence of HCI secretion, inactive pepsinogen is not converted into the active enzyme pepsin
 - (b) Enterokinase will not be released from the duodenal mucosa and so trypsinogen is not converted to trypsin
 - (c) Gastric juice will be deficient in chymosin
 - (d) Gastric juice will be deficient in pepsinogen

22. Match the following and choose the correct combination from the options given

	Column I	-Ale	Column II
A.	Ptyalin	1.	Lipids
B.	Pepsin	2.	Starch
C.	Steapsin	3.	DNA
D.	Nuclease	4.	Proteins

[MP PMT 1994; Kerala PMT 2004]

- (a) A-1, B-3, C-2, D-4
- (b) A-1, B-4, C-3, D-2
- (c) A-2, B-4, C-1, D-3
- (d) A-2, B-3, C-1, D-4
- (e) A-4, B-3, C-1, D-2
- Cells of the pancreas is not digested by their own enzymes because [MP PMT 2003]
 - (a) Enzymes are secreted in inactive form
 - (b) Cells are not lined by mucous membrane
 - (c) Enzymes are released only when needed
 - (d) None of the above
- When fat is in the stomach the secretion of gastrin is inhibited. This inhibition is due to [CPMT 1992]
 - (a) Presence of fat
- (b) Non-stimulation of vagus
- (c) Slow digestion of fat
- (d) Release of enterogastron
- Which of the following hormone stimulates the secretion of gastric juice [CMC Vellore 1993; CPMT 2002; BHU 2003; WB JEE 2010]

Or

Which of the following hormone helps in secretion of *HCl* from stomach [WB JEE 2008, 11]

- (a) Secretin
- (b) Gastron
- (c) Cholecystokinin
- (d) Gastrin
- 26. Cholecystokinin is a secretion of

[MP PMT 1992: WB JEE 2012]

- (a) Stomach which stimulates pancreas to release the pancreatic juice
- (b) Liver synthesised from cholesterol and controls secondary sexual characters
- (c) Duodenum and makes the gall bladder to contract and release bile
- (d) Goblet cells of ileum and stimulates the secretion of succus entericus
- 27. In rabbit proteins are digested by

[CPMT 1995]

- (a) Pepsin and trypsin
- (b) Trypsin and steapsin
- (c) Steapsin and pepsin
- (d) All the above
- 28. Which of the following is not a proteolytic enzyme

[Bihar MDAT 1995]

Or

Which of the following belongs to the class of pepsin and trypsin

Or

Enzyme released from kidney is

[AFMC 2008]

- (a) Pepsin
- (b) Trypsin
- (c) Erepsin
- (d) Renin

- 29. Identify the correct set which shows the name of the enzymes from where it is secreted and substrate upon which it acts [Odisha PMT 2002]
 - (a) Pepsin-stomach wall- casein
 - (b) Ptyalin- intestine-maltose
 - (c) Chymotrypsin-salivary gland-lactose
 - (d) Ptyalin pancreas-lipid CoA
- Trypsin converts

[MP PMT 1995]

- (a) Fats into fatty acids
- (b) Starch and glycogen into maltose
- (c) Proteins into peptones
- (d) Sucrose into glucose and fructose
- 31. Islets of Langerhans produce

[MP PMT 1995]

- (a) Insulin
- (b) Rennin
- (c) Ptyalin
- (d) HCI
- 32. Which of the following is a gastro-intestinal enzyme

[AFMC 1997; WB JEE 2011]

- (a) Cholinestrase
- (b) Enterokinase
- (c) Secretin
- (d) Prolactin
- 33. Secretin

- [AMU (Med.) 2009]
- (a) Stimulates enzyme secretion by pancreas, inhibits acid secretion in stomach, stimulates gall bladder
- (b) Stimulates bicarbonate secretion by pancreas, inhibits acid secretion in stomach, stimulates bicarbonate secretion by liver
- (c) Stimulates acid secretion in stomach, potentiates action of CCK, inhibits intestinal movement
- (d) Stimulates gall bladder, inhibits acid secretion in stomach, stimulates bicarbonate secretion by pancreas
- 34. The gastrointestinal hormone which stimulates insulin secretion is [AMU (Med.) 2012]
 - (a) Gastrin
- (b) CCK
- (c) Secretin
- (d) GIP
- 35. Gastric enzymes are
- (4) 0...
- (a) Pepsinogen
- (b) Prorennin
- (c) Gastric lipase
- (d) All of these
- **36.** Enzymes, vitamins and hormones can be classified into a single category of biological chemicals, because all of them

[AIIMS 1992; CBSE PMT 2005]

[CPMT 2009]

- (a) Are proteins
- (b) Enhance the oxidative metabolism
- (c) Aid the regulating mechanism
- (d) Are synthesised within the body of an organism
- 37. The hormone 'secretin' stimulates secretion of

[CBSE PMT 1990; MP PMT 1996, 2002, 07, 12; Pb. PMT 1999, 2000; BHU 2000]

- (a) Pancreatic juice
- (b) Bile juice
- (c) Salivary juice
- (d) Gastric juice

38.	V	What is common among amylase, rennin and trypsin [CBSE PMT 1997; Pb. PMT 1999, 2000; BHU 2001]	3.	The number of essential amino acids in adult human is
	(2	a) These all are proteins		[Odisha JEE 2009
		These all are proteolytic enzymes		(a) Nine (b) Eight
		These are produced in stomach	200	(c) Four (d) Seven
		i) These act at a pH lower than 7	4.	Which one of the following statements is not correct
39.		holecystokinin and duocrinin are secreted by		[CBSE PMT 2014
	_	[CBSE PMT 1999; AIEEE Pharmacy 2003]		(a) Retinal is a derivative of vitamin C
) Intestine (b) Pancreas		 (b) Rhodopsin is the purplish red protein present in rod only
40.) Adrenal cortex (d) Thyroid gland Thich part of body secretes the hormone secretin		(c) Retinal is the light absorbing portion of visua
		[MP PMT 1994, 95; CBSE PMT 1999; AIEEE Pharmacy 2003]		photopigments (d) In retina the rods have the photopigment rhodopsin
	(a) Ileum (b) Stomach		while cones have three different photopigments
	(c) Duodenum (d) Oesophagus	5.	Inadequate protein intake leads to kwashiorkor. The
41.	W	hat is the substrate for lipase enzyme [WB JEE 2012]		subsequent edema is most closely related to inadequate
	(a) Protein (b) Carbohydrate		synthesis of which protein [DUMET 2009

, (b) $-(p)$, (c) $-(t)$, (d) $-(s)$, (e) $-(q)$

(a)
$$(a) - (r)$$
, $(b) - (p)$, $(c) - (r)$, $(d) - (s)$, $(e) - (q)$
(e) $(a) - (r)$, $(b) - (s)$, $(c) - (p)$, $(d) - (t)$, $(e) - (q)$

107. Iodine test used to detect

[DPMT 2003]

(a) Protein

(b) Fat

(c) Carbohydrate

(d) Chitin

108. Which one of the following is antioxidant vitamin

[DPMT 2003; BHU 2003]

(a) Vitamin C, E, A

Vitamin B_1 , B_4

(c) Vitamin A, D, E

(d) Vitamin B3, B5

109. Vitamin-C is mainly helpful in

[MP PMT 2006]

(a) Growth of bones

(b) Formation of connective tissue

(c) Treatment of anaemia

(d) Formation of visual pigment

110. Continuous bleeding from an injured part of body is due to [CBSE PMT 2002; MP PMT 2003] deficiency of

(a) Vitamin A

(b) Vitamin B

(c) Vitamin K

(d) Vitamin E

111. Which group of three of the following five statement (1-5) contain is all three correct statements regarding beri-beri

1. A crippling disease prevalent among the native population of sub-Saharan Africa

2. A deficiency disease caused by lack of thiamine (vitamin B_1)

A nutritional disorder in infants and young children when the diet is persistently deficient in essential protein

Occurs in those countries where the staple diet is polished rice

The symptoms are pain from neuritis, paralysis, muscle wasting, progressive oedema mental deterioration and [CBSE PMT 2005] finally heart failure.

(a) 2, 4 and 5

(b) 1, 2 and 4

(c) 1, 3 and 5

(d) 2, 3 and 5

112. 'Burning feet syndrome' is due to deficiency of

(a) Vitamin D

(b) Vitamin A

(c) Vitamin B₃

(d) Vitamin B₅

113. A patient of diabetes mellitus excretes glucose in urine even when he is kept in a carbohydrate free diet. It is because

[Odisha JEE 2005]

(a) Fats are catabolised to form glucose

(b) Amino acids are catabolised in liver

(c) Amino acids are discharged in blood stream from liver

(d) Glycogen from muscles is released in blood stream.

114. The disease due to inflammation of vermiform appendix of [CBSE PMT 1993] digestive system is known as

(a) Amoebic dysentery

(b) Intestinal cancer

(c) Appendicitis

(d) None of the above

115. Which of the following is related with vitamin B_2

[AFMC 1997]

Or Riboflavin is essential in our diet, as it is required for the synthesis of

(a) FMN / FAD

(b) NAD

(c) NADH

(d) NADH,

116. The method of intake of food in case of ciliate Paramaecium

(a) Holozoic

(b) Saprozoic

(c) Saprophytic

(d) Parasitic

117. Which one of the following is a matching pair of a certain body feature and its value/count in a normal human adult

[AIIMS 2003]

(a) Urea 5-10 mg/100 ml of blood

(b) Blood sugar 80-100 mg/100 ml

(c) Total blood volume 3-4 litres

(d) ESR in Wintrobe method 9-15 mm per hour in males and 20-34 mm per hour in females

118. Average kilocalorie of energy needed by woman is

[NCERT; Odisha JEE 2005]

(a) Less than man

(b) More than man

(c) Equal to man

(d) Cannot be predicted

119. An average man needs approximately

[NCERT; CBSE PMT 1999; MP PMT 2004]

(a) 2900 K cal. energy/day (b) 500 K cal. energy/day

(c) 1000 K cal. energy/day (d) 2000 K cal. energy/day

120. The people dependent exclusively on maize diet, are more [AIEEE Pharmacy 2003] likely to suffer from

(a) Rickets

(b) Pellagra

(c) Beri-beri

(d) Dysentery

121. Vasco de Gama (1498) sailed to explore India with 180 companions but most of them died due to

(a) Rickets

(b) Pellagra

(c) Scurvy

(d) Xerophthalmia

122. Anti-infection vitamin is

(a) B₁₂

(b) A

(c) D

(d) K

123. Chemical formula of 'Retinol-1' is

(a) $C_6H_5NO_2$

(b) $C_3H_{10}O_3N$

(c) C₂₀H₃₀O

(d) C₂₈H₄₄O

124. Vitamin essential for formation of collagen is

(a) A

(b) E

(c) B₁₂

(d) C

125. Which one of the following is the correct matching of a vitamin, its nature and its deficiency disease

[CBSE PMT 2004; BCECE 2005]

(a) Vitamin A - Fat-soluble - Beri-beri

(b) Vitamin K - water-soluble - Pellagra

(c) Vitamin A - Fat-soluble - Night blindness

(d) Vitamin K - Fat-soluble - Beri-beri

NCERT Exemplar Questions

1. Select what is not true of intestinal villi among followings

[NCERT]

- (a) They possess microvilli
- (b) They increase the surface area
- (c) They are supplied with capillaries and the lacteal vessels
- (d) They only participate in digestion of fats
- Hepato-pancreatic duct opens into the duodenum and carries [NCERT]
 - (a) Bile
 - (b) Pancreatic juice
 - (c) Both bile and pancreatic juice
 - (d) Saliva
- One of the following is not a common disorder associated with digestive system [NCERT]
 - (a) Tetanus
- (b) Diarrhoea
- (c) Jaundice
- (d) Dysentery
- A gland not associated with the alimentary canal is [NCERT]
 - (a) Pancreas
- (b) Adrenal
- (c) Liver
- (d) Salivary glands
- Match the two columns and select the correct among options given

Column I

Column II

- A. Biomacromolecules of food i. Alimentary canal and associated gland
- B. Human digestive system
- ii. Embedded in jawbones
- C. Stomach
- iii. Outer wall of visceral organs
- D. Thecodont
- iv. Converted into simple substances
- E. Serosa
- v. J-shaped bag like structure

Options

[NCERT]

INCERTI

- (a) A-ii, B-i, C-v, D-iii, E-iv
- (b) A-iv, B-i, C-v, D-ii, E-iii
- (c) A-i, B-ii, C-iii, D-iv, E-v
- (d) A-i, B-iii, C-ii, D-iv, E-v
- Match the two columns and select the right one among options given

Column I

Column II

- A. Duodenum
- i. A cartilaginous flap
- B. Epiglottis
- ii. Small blind sac
- C. Glottis

 iii. 'U' shaped structure
 emerging from the stomach
- D. Caecum
- iv. Opening of wind pipe

Options

- (a) A-i, B-ii, C-iii, D-iv
- (b) A-iv, B-iii, C-ii, D-i
- (c) A-iii, B-i, C-iv, D-ii
- (d) A-ii, B-iv, C-i, D-iii

- Match the enzyme with their respective substrate and choose the right one among options given
 - A. Lipase
- i. Dipeptides
- B. Nuclease
- ii. Fats

D-ii

- C. CarboxypeptidaseD. Dipeptidases
- iii. Nucleic acids
- iv. Proteins, peptones and proteoses

Options

[NCERT]

- (a) A-ii, B-iii, C-i, D
- (b) A-iii, B-iv, C-ii, D-i
- (c) A-iii, B-i, C-iv,
- (d) A-ii, B-iii, C-iv, D-i
- Liver is the largest gland and is associated with various functions, choose one which is not correct [NCERT]
 - (a) Metabolism of carbohydrate
 - (b) Digestion of fat
 - (c) Formation of bile
 - (d) Secretion of hormone called gastric
- (d) Secretion of normone called gastric
 - Mark the right statement among the following [NCERT]
 - (a) Trypsinogen is an inactive enzyme
 - (b) Trypsinogen is secreted by intestinal mucosa
 - (c) Enterokinase is secreted by pancrease
 - (d) Bile contains trypsin

Critical Thinking

Objective Questions

- 1. This is the common passage for bile and pancreatic juices
 - [NCERT; AMU (Med.) 2010, 12]
 - (a) Ampulla of Vater
- (b) Ductus Choledochus
- (c) Duct of Wirsung
- (d) Duct of Santorini
- 2. Digestion in *Hydra* takes place within [Odisha JEE 2009]
 - (a) Pelvic cavity
- (b) Abdominal cavity
- (c) Pericardial cavity

 Which is the character
- (d) Gastrovascular cavity
- Which is the characteristic lining of stomach of mammals [MP PMT 1993]
 - (a) Paneth cells
- (b) Deiter cells
- (c) Oxyntic cells
- (d) Kupffer cells
- Fatty acid and glycerol are first taken up from alimentary canal by [AFMC 1994]
 - (a) Villi

4.

- (b) Blood capillaries
- (c) Hepatic portal vein
- (d) Lymph vessels
- 5. Erythropoiesis starts in
- (d) Lymph vessels [DUMET 2009;
- Maria alla Tabana Silat
- AIPMT (Cancelled) 2015]

(b) Liver

- (a) Kidney
- (d) Red bone marrow
- (c) Spleen
- (u) Neu bone marro
- 6. In rabbit the colour of bile juice is
 - (a) Colourless due to the presence of sodium and potassium taurocholate
 - (b) Green due to the accumulation of biliverdin
 - (c) Red due to the accumulation of haemoglobin
 - (d) Yellow due to the presence of bilirubin
- During absorption of carbohydrates in the blood the most rapidly transported monosaccharide is [BHU 2012]
 - (a) Glucose
- (b) Galactose
- (c) Fructose
- (d) Sucrose

- 8. The wall of the stomach is protected against the action of [J & K CET 2010]
 - (a) Epidermal layer
- (b) Mesodermal layer
- (c) Mucous layer
- (d) Muscular layer
- 9. Column I contains names of the sphincter muscles of the alimentary canal and column II contains their locations. Match them properly and choose the correct answer

	Column I		Column II
A.	Sphincter of ani internus	1.	Opening of hepatopancreatic duct into duodenum
B.	Cardiac sphincter	2.	Between duodenum and posterior stomach
C.	Sphincter of Oddi	3.	Guarding the terminal part of alimentary canal
D.	Ileocaecal sphincter	4.	Between oesophagus and anterior stomach
E.	Pyloric sphincter	5.	Between small intestine and bowel

[NCERT; KCET 2011]

- (a) A-3, B-2, C-4, D-1, E-5
- (b) A-2, B-5, C-1, D-4, E-3
- (c) A-3, B-4, C-1, D-5, E-2
- (d) A-4, B-3, C-1, D-2, E-5
- The pungent odour of faeces is due to presence of

[MP PMT 1997]

- (a) Indole
- (b) Skatole
- (c) Various gases
- (d) All the above
- Maximum percentage of lipoprotein is present in [DPMT 2007]
 - (a) Chylomicron
- (b) HDL
- (c) VDL
- (d) VLDL
- Where do certain symbiotic microorganisms normally occur in human body [NCERT; CBSE PMT (Mains) 2012]
 - (a) Caecum
 - (b) Oral lining and tongue surface
 - (c) Vermiform appendix and rectum
 - (d) Duodenum
- 13. For the enzyme action

[BHU 1995]

- (a) Value of Km is unchange (b) Value of Km is low
- (c) Value of Km is constant (d) Value of Km is high
- 14. Inhibition of gastric secretion is brought about by

[CMC Vellore 1993; CBSE PMT 1994; MP PMT 2003; CPMT 2005]

Or

Which of these is not an enzyme of digestive system

- (a) Cholecystokinin
- (b) Pancreozymin
- (c) Gastrin
- (d) Enterogastron
- A principal gastrointestinal hormone is
 - (a) Prolactin
- (b) Choline esterase
- (c) Secretin
- (d) Acetyl
- The activator of intestinal juice is 16.

[JIPMER 1993]

Mechanical stimulation of villi by the food produces a hormone which is known as [RPMT 2005]

- (a) Succus entericus
- (b) Secretin
- (c) Enterocrinin
- (d) Enterozymase

Anxiety and eating spicy food together in an otherwise normal human, may lead to

[NCERT; CBSE PMT (Pre.) 2012]

- (a) Indigestion
- (b) Jaundice
- (c) Diarrhoea
- (d) Vomiting
- Wisdom teeth in human is 18.
- [CPMT 2002; RPMT 2005]
- (a) 3rd molar & 4 in number (b) 3rd molar & 2 in number
- (c) 2nd molar & 4 in number (d) 2nd molar & 2 in number
- 19. In the stomach, gastric acid is secreted by the

[NEET (Phase-I) 2016]

- (a) Gastrin secreting cells
- (b) Parietal cells
- (c) Peptic cells
- (d) Acidic cells
- 20. Which of the following can be called 'animal starch'

[AIIMS 1993]

[BHU 2008]

- (a) Hemicellulose
- (b) Glucose
- (c) Glycogen
- (d) Chitin
- 21. One of the following is needed for the conversion of trypsinogen into trypsin [NCERT; CBSE PMT 1995, 99: AFMC 1996; BHU 2000; Kerala PMT 2008]

Trypsinogen is an inactive enzyme secreted by the pancreas.

- It is activated by (a) HCI
- [WB JEE 2016] (b) Enterokinase
- (c) Lipase
- (d) Zymase
- 22. Leison in ventromedial hypothalmus (a) Increases hunger
 - [MP PMT 2004]
 - (c) Do not change hunger
- (b) Decreases hunger (d) Stop eating
- 23. Antihaemorrhagic vitamin is (a) Vitamin A
- (b) Vitamin B
- (c) Vitamin C 24.
 - (d) Vitamin K The mine workers are most likely to suffer from
 - (a) Beri-beri
- (b) Osteomalacia
- (c) Scurvy
- (d) Xeropthalmia
- Write proper option by matching column I, II and III 25.

(Na	umn I me)	0.00	umn II ryme)	100000000000000000000000000000000000000	umn III nction)
(i)	Gastric Juice	(P)	Chymo- trypsinogen	(A)	Dipeptide convert into amino acid
(ii)	Intestinal Juice	(Q)	Ptyalin	(B)	Proteoses convert into small polypeptides
(iii)	Saliva	(R)	Renin	(C)	Casein convert into paracasein
(iv)	Pancreat ic juice	(S)	Erepsin	(D)	Conversion of starch into maltose

[GUJCET 2015]

- (a) (i R C) (ii S A) (iii Q B) (iv P D)
- (b) (i R C) (ii S A) (iii Q D) (iv P B)
- (c) (i S D) (ii R C) (iii P B) (iv Q A)
- (d) (i Q A) (ii P C) (iii R B) (iv S D)
- Wound healing is enhanced by a vitamin [MP PMT 2002] 26.
 - (a) A
- (b) C
- (c) D
- (d) E
- Which of the following pair is characterised by swollen lips, thick pigmented skin of hands and legs and irritability

[CPMT 2004]

- (a) Iodine
- Goitre
- (b) Protein
- Kwashiorkor
- (c) Thiamine
- Beri-Beri
- (d) Nicotinamide
- Pellagra

804 Digestion and Absorption Select the mismatch between a vitamin and its deficiency disease, among the following [AIEEE Pharmacy 2004] (a) Riboflavin-slow clotting of blood Niacin-damage to skin and lining of intestine Ascorbic acid-scurvy (c) Thiamine-damage to nerves and heart. The delicious food generally makes mouth watery. It is due 29 [J & K CET 2002] (b) Neural response (a) Hormonal response (c) Olfactory response (d) Optic response A triglyceride molecule has or A typical fat molecule is made 30. [Kerala CET 2003; NEET (Phase-I) 2016] (a) Three fattyacids with one glycerol molecule (b) Three fattyacids with two glycerol molecule (c) Two fattyacids with two glycerol molecules (d) One fattyacid with one glycerol molecule Excessive stimulation of vagus nerve in humans may lead to [AIIMS 2003] (a) Hoarse voice (b) Peptic ulcers (c) Efficient digestion of proteins (d) Irregular contractions of diaphragm Protein deficiency in children is called [KCET 1994; CBSE PMT 1998; BHU 2003; DPMT 2007; AFMC 2008; **CPMT 2008]** Or In Africa and South-east Asia, people like to have much bread and butter than pulses. They suffer (a) Obesity (b) Marasmus (d) Kwashiorkor (c) Diabetes The intestine is different from the stomach by the presence [NCERT; AIIMS 1993] (b) Villi (a) Digestive gland (d) Serosa (c) Sub-mucosa In the empty stomach, mucosal folds appear. They are 34. [MP PMT 2002] called (a) Fiveoles (b) Ancinura angularis (c) Rugae (d) None Which of the following controls the peristaltic movement of 35. [BHU 2002] the intestine (a) Sacral plexus (b) Brachial plexus (c) Discoidal plexus (d) Auerbach's plexus Secretin hormone is secreted by [CBSE PMT 2002] 36. (a) Liver (b) Pancreas (c) Intestine (d) Brunner's glands Consider the following statements 37. A. The anti pellagra vitamin is nicotinamide present in milk, yeast, meat and leafy vegetables B. Crypts of Leiberkuhn are present in the liver C. Steapsin is the pancreatic amylase [Kerala PMT 2007] (a) A and B correct (b) B and C correct (d) A and C correct (c) A and C incorrect (e) B and C incorrect [BHU 2002] Digestion process in humans is 38. (a) Extracellular (b) Intracellular (d) Both (a) and (c) (c) Intercellular Mumps are caused due to 39 (a) Excessive cold

(b) Viral infection in tonsils

(c) Viral infection of parotid salivary glands

(d) Viral infection of zygomatic glands

- The folds of Kerkring are developed in (b) Jejunum (a) Duodenum (d) Large intestine (c) Ileum 41.
 - [JIPMER 2002] Meckel's diverticulum is found in (a) Ileum (b) Appendix (d) Rectum (c) Pylorus
- Which of the following carries glucose from digestive tract to 42. [CBSE PMT 1999; Pb. PMT 2000; BHU 2001]
 - (a) Hepatic artery (b) Pulmonary vein (d) Renal portal system (c) Hepatic portal vein Which of the following sugars is absorbed from the small
- 43. [CBSE PMT 2001] intestine by facilitated diffusion (a) Fructose (b) Glucose
- (d) Lactose (c) Sucrose Mammals drink water and also obtain it from [MP PMT 2013]
- (a) Break down of glycogen into glucose
 - (b) Secretion of saliva
 - (c) Conversion of oxyhaemoglobin to haemoglobin
 - (d) Oxidation of glucose
- 45. Select the correct match of the digested products in humans given in Column I with their absorption site and mechanism **INEET 2013]** in Column II

	Column I	Column II
(a)	Cholesterol, maltose	Large intestine, active absorption
(b)	Glycine, glucose	Small intestine, active absorption
(c)	Fructose, Na+	Small intestine, passive absorption
(d)	Glycerol, fatty acids	Duodenum, move as chilomicrons

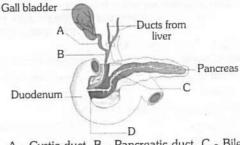

A healthy person eats the following diet-5gm raw sugar, 4 gm albumin, 10 gm pure buffalo ghee adulterated with 2gm vegetable ghee (hydrogenated vegetable oil) and 5 gm lignin. How many calories he is likely to get [NEET (Karnataka) 2013]

(a) 126

(b) 164

(c) 112 (d) 144

The given figure is a duct system of liver, gall bladder and pancreas. Identify the names of ducts from A to D [NCERT]

- (a) A Cystic duct, B Pancreatic duct, C Bile duct, D -Hepato - pancreatic duct
- (b) A Cystic duct, B Bile duct, C Hepato pancreatic duct, D - Pancreatic duct
- (c) A Bile duct, B Cystic duct, C Pancreatic duct, D -Hepato - pancreatic duct
- (d) A Cystic duct, B Bile duct, C Pancreatic duct, D -Hepato - pancreatic duct

48. Which option is correct for the region labelled as 'a' and 'b' in the given diagram of transverse section of gut

[GUJCET 2014]

- (a) a = Nerve. b = Circular muscle
- (b) a = Sub mucosal plexus of vessels,

b = Mucosal gland

(c) a = Villi.

b = Mucosal gland

(d) a = Longitudinal muscle.

b = Muscularis mucosa

- 49. Pituitary gland is located in 'a', which is a 'b' and 'c' bone [GUJCET 2014]
 - (a) a = Sella turcica, b = Raised surface, c = Ethmoid
 - (b) a = Reketh's pauch, b = Depression, c = Nasal
 - (c) a = Sella turcica, b = Depression, c = Sphenoid
 - (d) a = Reketh's pauch, b = Depression, c = Sphenoid
- 50. The enzyme that is not present in succus entericus is

[AIPMT 2015]

(a) Nucleases

(b) Nucleosidase

- (c) Lipase
- (d) Maltase
- Good vision depends on adequate intake of carotene rich

Select the best option from the following statements

- (A) Vitamin A derivatives are formed from carotene
- (B) The photopigments are embedded in the membrane discs of the inner segment
- (C) Retinal is a derivative of Vitamin A
- (D) Retinal is a light absorbing part of all the visual photopigments

Options

[NEET 2017]

- (a) (A) and (B)
- (b) (A), (C) and (D)
- (c) (A) and (C)
- (d) (B), (C) and (D)

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- If both the assertion and the reason are true and the reason (a) is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- If the assertion is true but the reason is false (c) (d)
- If both the assertion and reason are false
- If the assertion is false but reason is true (e)
- 1. Assertion Blood sugar level falls rapidly hepatectomy.
 - The glycogen of the liver is the principal Reason source of blood sugar.
- [KCET 2009] Assertion Arachidic acid is an unsaturated fatty acid Reason

There are present one or more double bonds between carbon atoms unsaturated fatty acids [AIIMS 2007]

- 3. Assertion Rumen of alimentary canal of ruminant animals harbour numerous bacteria and protozoa.
 - Reason Bacteria and protozoa help in the secretion of gastric juice in the rumen.

Assertion Many tube like glands are present in the wall of small intestine.

Reason These glands secrete enzymes DNAse and RNAse into the intestinal juice.

5. Assertion Minerals are not biologically substances.

Reason Some individuals suffer anaemia due to deficiency of copper.

[AIIMS 2009] Assertion Thick layers of muscles are present in the

wall of alimentary canal.

Reason These muscles help in the mixing of food materials with the enzymes coming from different glands in the alimentary canal.

[AIIMS 2007, 10]

7. alcoholic fermentation, the hexose Assertion molecule is converted into glucose and fructose.

Reason Alcoholic fermentation anaerobic respiration brough about by enzyme zymase. [AIIMS 1996]

8 Assertion Insulin is secreted by a-cells of islets of langerhans of pancreas.

> Reason Insulin promotes conversion of glucose to glycogen. [AIIMS 1996]

Assertion Carbohydrates are more suitable for the production of energy in the body than proteins and fats.

Carbohydrates can be stored in the tissues

Reason as glycogen for use in the production of energy, whenever necessary.

Assertion The amino acid glycine comes under the category of nonessential amino acids.

Reason This is due to the fact that it can not be synthesised in the body. [AIIMS 2010]

Assertion Scurvy is caused by deficiency of vitamin. Reason Deficiency of ascorbic acid causes scurvy.

[AIIMS 2001] 12. Assertion The main part of carbohydrate digestion

takes place in small intestine. Reason Here pancreatic amylase

carbohydrates into lactose. [AIIMS 1995] 13. Assertion In alcoholic drink, the alcohol is converted

into glucose in the liver. Liver cells are able to produce glucose from Reason alcohol by back fermentation.[AIIMS 1996]

Assertion Adult human being is not perfect in digestion of milk.

With age, man produces little or no lactase Reason in the intestinal juice.

Trypsin helps in blood digestion of 15. Assertion predator animals.

Reason Trypsin hydrolyses fibrinogen.

Volume and fluidity of intestinal contents Assertion have increased in a person.

Reason The person drank sea water.

17. Assertion Sea-faring fishermen sometimes eat raw fish. Reason They can be deficient of Vitamin B₁.

[AIIMS 2001]

UNIVERSAL BOOK DEPOT 1960

806 Digestion and Absorption

18. Assertion

Starch is hydrolysed by ptyalin to maltose.

Reason

Sucrase hydrolyses sucrose to lactose.

[AIIMS 2001]

19. Assertion

Cold blooded animals have no fat layer.

Reason

Cold blooded animals use their fat for

metabolic process during hibernation.

[AIIMS 1997]

20. Assertion

Absorption of digested food mainly occurs

in the stomach.

Reason

Stomach produces the hormone gastrin and the intrinsic factor and it liquifies

ingested food.

[AIIMS 1996]

Answers and Solutions

Digestive system

- 1. The lower Jaw of man is formed by the fusion of dentary bone only.
- Dental formula of Rabbit is $\frac{2,0,3,3}{1,0,2,3} \times 2 = \frac{16}{12} = 28$ 2.
- 3. (b) Upper canines are most developed in Walrus.

- (b) Crown of the teeth is covered by the hardest substance 4. of the body called enamel.
- 5. Foliate papillae are present only on tongue of rabbit.
- 12. (c) In frog teeth are pre maxillary, maxillary and vomerine.
- 13. (d) Tongue forms the floor of the oral cavity and it helps in the act of swallowing, help in mixing saliva with the food, help in speaking etc.
- (a) Dental formula for milk teeth is $\frac{2102}{2102}$ so premolars are 14.
- 15. Taste buds for bitter taste are found on tongue at posterior part while anterior tip for sweetness and lateral sides are responsible for sour.
- 17. If a person suddenly starts coughing while swallowing food, it is due to improper movement of epiglottis. If the glottis is not properly closed some food can enter respiratory tract.
- In mammals, the digestion starts from mouth. Mouth contain 3-pair salivary gland which secretes saliva. Saliva contains a starch splitting enzyme ptyalin which acts on cooked starch changing them into a sugar maltose, isomaltose and limit dextrin.
- (c) The dental formula of Rabbit is $\frac{2033}{1023} = \frac{8}{6} \times 2 = 28$, so 20. 28 teeth occur in rabbit, canines are absent and Diastema is present between incisor and premolar.
- 21. (b) Premolar and molar teeth with transverse ridges called lophos, so, premolar and molar are lophodont occurs in rabbit and elephant.
- 23. Upper incisor of an elephant is an enormously enlarged, called tusk teeth.
- 25. The third molar appear very late and are called wisdom teeth. From evolutionary point of view it is vestigeal structure.
- 26. (d) Teeth of frog are homodont, acrodont and polyphyodont. They are small, sharp and backwardly directed which are not meant for mastication but for preventing escape of prey.
- Dentine forming cells, the odontoblasts line the pulp 27. cavity of teeth.
- 28. Lacteals are central lymph vessel found in villi of intestine. It is related to absorption of fats.
- 29. The wall of alimentary canal is made up of four basic layers. First of all there is serosa which is a thin membranous covering around oesophagus. Then there is muscle layer-outer layer of longitudinal muscles and inner layer of circular muscles. Last there is submucosa which contains a few oesophageal glands. Then comes mucosa which have several layers of flattened cells.
- (b) Dental formula of human is $\frac{2,1,2,3}{2,1,2,3} = \frac{8}{8} \times 2 = 32$. It 30. shows the number of incisor 2, canine 1, premolar 2 molar 3 in each half upper and half lower jaw with 32 teeth in buccal cavity.
- 31. (c) Animals which eat their own faeces are called pseudo ruminants or coprophagus and phenomenon is known as pseudo rumination or coprophagy. e.g., Rabbit, Guinea pig.
- 34. The muscular contraction in alimentary canal is known (c) as peristalsis due to which the food passes from front to backward direction in the lumen of alimentary canal.

- 35. (a) Its large broader anterior part is called cardiac stomach, while the short narrower posterior part the pyloric stomach. So fundic part is absent in Stomach of frog.
- 36. (b) The fundic part of stomach consist 2 type of cells, chief or zymogenic cell secrets pepsin and oxyntic or parietal cell secretes HCI.
- 38. (b) Inner lining of gut, stomach and liver is composed of simple columnar epithellium, single layer of non ciliated rectangular cells contains goblet cells, nuclei at basis of cell.
- 39. (b) The mucosal lining of the oesophagus of mammals is made of squamous epithelium, several layers of cell deep layers, deep layers are cuboidal to columnar surface layers flat and scale like.
- **41.** (a) Casein is a phosphoprotein found in milk. It is digested by rennin enzyme.
- **42.** (b) The site of protein digestion is stomach where pepsin enzyme occur which changes protein to peptones + proteases.
- 43. (b) Stomach of ruminants is divided in 4 chamber, Rumen, Reticulum, omasum and abomasum. Some ruminants like camel and deer do not have omasum.
- 46. (c) In the wall of intestine, lymphatic tissue are present called peyer's patches. Peyer's patches are a group of lymph nodules that are most numerous in the ileum and produce lymphocyte.
- 50. (d) Peyer's patches are found in the ileum of mammals.
- (d) Water is mostly absorbed in colon. Colon is a part of large intestine.
- (b) The intestinal juice or succus entericus is secreted by crypts of lieberkuhn.
- **55.** (a) Goblet cells are specialized unicellular cells that secrete mucus and form glands of the epithelium the stomach, intestine and part of the respiratory tract.
- 57. (c) Brunner's gland are found in submucosa of duodenum.
- **58.** (a) Chief cells or pepsinogenic or zymogenic cells secretes pepsinogen and prorennin. These cells are situated in fundic part of stomach.
- 59. (d) Intestinal villi are mainly concerned with the absorption, the main function of intestinal villi is to provide large surface area for absorption.
- 60. (a) Crypt of lieberkuhn is a type of simple tubular glands in which secretory portion is straight and tubular.
- **62.** (a) Vermiform appendix is vestigeal organ of man which is found in alimentary canal.

Digestive glands

- 1. (d) The endocrine part of pancreas is known as islets of Langerhans which contains 4 type of cell α -cell, β -cells, γ -cells and Δ -cell.
- (d) Brunner's glands are present in the submucosa of duodenum and secrete HCO₃.
- (a) Bile salts emulsify the fats and later on digested by enzyme lipase.
- (b) Parotid glands are one pair largest salivary gland which is situated below ear (pinna).

- (c) Pancreatic juice is also called as complete digestive juice. It contains trypsin, chymotrypsin, amylase, and lipase, which digest all types of food materials.
- (b) Gastric juice of infants contains pepsinogen, lipase and rennin.
- 10. (b) Ptyalin is slightly acidic because its pH value is 6.8.
- (d) Liver cell synthesize vitamin A from carotene and store vitamines A, D and B₁₂.
- (c) Argentaffin cells are generally located at the base of gastric glands and secrete serotonin.
- 15. (b) Pancreas is a mixed gland its exocrine part release enzyme and endocrine part release hormones so, pancreatic juice and hormones are secreted by different cell.
- **16.** (b) Amylase is present in saliva it is slightly acidic nature because its *pH* value is 6.8.
- (a) Intestinal juice is a clear yellow fluid with slightly alkaline nature pH of 7.6, contains water, mucus and enzymes.
- (b) Intestinal juice or succus entericus is mainly secreted by crypts of lieberkuhn.
- 20. (c) Liver of rabbit is partly divided into 5 lobes; three lobes on left side are a small spigelian, left lateral and left central, while two lobes on the right side are caudate and right central or cystic.
- 24. (a) Sub maxillary and sub lingual glands are salivary gland secretes saliva, which participates in digestion of starch.
- **25.** (b) Human beings have 3 pairs of salivary glands parotid, submandibular and sublingual.
- 26. (a) Ptyalin is an enzyme of salivary juice.
- 27. (b) Ptyalin (salivary amylase) and pancreatic amylase are the starch spliting enzyme released by salivary gland and pancreas.
- 28. (a) A lubricant mucin in saliva is made up of glycoprotein.
- 29. (c) Liver detoxifies and neutralises harmful substances.
- **30.** (c) The trypsin enzyme is present in pancreatic juice which is secreted by pancreas.
- **31.** (b) Bilirubin and biliverdin are bile pigments and are present in the bile juice.
- 33. (b) By cystic duct bile juice passes into gall-bladder from liver.
- 34. (d) Infra orbital salivary gland is absent in man while in other mammals such as rabbit it is found.
- 35. (c) Bile juice contains bile salts and bile pigments.
- 36. (c) Gastric juices have pH 2-3.7.
- 37. (b) The bacteria are found in the colon which infact are the main source of vitamin-B₁₂ as vitamin-B₁₂ is not found in plants. Few micro-organisms of the rumen of stomach of ruminant mammals also synthesize large quantity of vitamin-B₁₂.
- 38. (b) In human body glycogen is stored in liver and muscles both total 400 gm. glycogen stored, 100 gm. in Liver and 300 gm. in muscles.
- 39. (a) Gastric juice is secreted by gastric glands. It consist pepsin, rennin, lipase.
- (d) Arginase is found in liver. It is very important enzyme for ornithine cycle.
- (c) Bile has no digestive enzymes and hence, no chemical action on food.

UNIVERSAL BOOK DEPOT 1960

- **48.** (c) The chief function of bile is emulsification of fats and make easy digestion of fats.
- **49.** (b) Pancreatic juice is secreted from pancreas its *pH* about 8.4.
- **50.** (b) Glycogenesis and glycogenolysis both process found in liver.
- 52. (d) Bile juice synthesis in liver helps in digestion of fats but it does not contains any digestive juice so liver is a organ which does not produce any digestive enzyme.
- **56.** (d) Intestinal juice contains many enzymes like maltase, sucrase, lactase etc.
- 57. (a) The largest gland in human body is liver.
- 60. (b) Caudate is the part of right lobe of liver.
- 61. (d) Daily secretion of saliva in man is about 1-1.5 lit.
- 62. (c) Lysozymes are found in saliva and tears both.

Physiology of digestion

- (d) Fructose is absorbed with the help of the carrier ions like Na⁺. This mechanism is called facilitated transport.
- (a) Lacteals are related with the absorbtion of fats are found in ileum.
- 4. (d) Pancreas is a digestive gland that secretes pancreatic juice. This juice acts on all type of food i.e., protein, starch, fat and nucleic acid. If pancreas is removed from the body, the digestion does not occur.
- (c) Chylomicron's are fat droplets coated with glycerol and protein.
- (d) Trypsin is a protein digesting enzyme occur in pancreatic juice.
- (a) Glycolysis is the first phase in the breakdown of glucose change in pyruvic acid occur in animal cell.
- (c) A good source of lipase is pancreatic juice which is converted to fat into fatty acid + Glycerol.
- (a) The end product of carbohydrate metabolism is CO₂ and H₂O.
- (c) Glycogen is a polysaccharide which is synthesized and stored in liver cell.
- (a) Emulsified fat is digested by lipase enzyme which is secreated by pancreatic juice, and intestinal juice.
- (d) Parietal or oxyntic cells release HCL required for the activation of pepsin.
- 23. (d) Digestion is defined as the conversion of non-diffusable food particle in diffusable food particle.
- 24. (b) Breaking of large fat droplets into fine emulsion by bile salt (Bile juice contain bile pigment and bile salt) of the liver.
- 26. (b) Because glucose is directly absorbed by the blood.
- **28.** (a) Those enzyme who digest protein called proteolytic enzyme, these are trypsin, peptidase, pepsin.
- **30.** (b) Rennin hydrolyses the milk protein casein into paracasein.
- **32.** (c) Gluconeogenesis is the process in which glucose is formed from substance other than the carbohydrates.
- 35. (a) Trypsin and pepsin both are endopeptidase enzyme. Trypsin digest proteins in alkaline medium while pepsin digest protein in acidic medium.
- 39. (a) All lipid digestion takes place in the small intestine. Fatty acids and glycerol are the digestion products of lipids.
- **40.** (a) Caecum is a small, pouch-like structure which ends into a tubular structure called vermiform appendix.

42. (a) Carbohydrate and fats (lipids) are chief energy source although proteins can also gives energy

Mad	cronutrient	Gross Caloric	Physiologic
Carl	oohydrate	Value Kcal/g	Value kcal/g
Prot		5.65	4
Fat		9.45	9

- 47. (a) Rennin enzyme is found in gastric juice. It is a milk coagulating proteinase. Rennin acts on casein (milk protein) and convert into calcium paracasinate. It is known as curdling of milk.
- 48. (c) Because protein is primarily digested in the acidic media.
- (d) Because human alimentary canal lacks cellulase enzyme and symbiotic micro-organisms.
- **54.** (b) Enzyme erepsin is found in intestinal juice. It converts peptones to amino-acids.
- **57.** (b) Bile salts help in the absorption of fats and fat soluble vitamin such as A, D, E and K in intestine.
- (d) Fatty substance are emulsified by bile salts secreted by liver.

Gastro intestinal hormones/Digestive enzymes

- 2. (d) Cholecystokinin-pancreozymine hormone is secreted by the epithelium of entire small intestine. It stimulates the gall bladder to release bile and pancreas to secrete and release digestive enzymes in the pancreatic juice.
- (c) Most of proteases are secreted in inactive forms called proenzyme. Propepsin and trypsinogen both are inactive form of proteolytic enzyme.
- (c) Secretin is secreted by the mucosa of duodenum and it stimulates the secretion of pancreatic juice and increase the duodenal movements. Thus it plays important role in digestion.
- (d) Amylase is a starch splitting enzyme similar to ptyalin, hydrolysing starch and glycogen to maltose, isomaltose and limit dextrin.
- (a) Isoenzymes are those enzymes which are found in more than one form having similar functions.
- 10. (c) Gastric glands are lined with three kinds of secreting cells zymogen (main, peptic or chief) cells, parietal cells and mucous cells. The main peptic or zymogen cells secrete digestive proenzyme namely pepsinogen and prorennin. HCl convert pepsinogen and prorennin into pepsin and rennin.
- 11. (d) Enteropeptidase or enterokinase is an enzyme involved in human digestion.
 Trypsin has an important role in the digestion of proteins in the anterior portion of the small intestine. It also activates other proteases in the pancreatic juice.
 Therefore in the absence of enterokinase the process of conversion of dipeptides to amino acids will be affected.
- (a) Rennin is secreted by the cells of stomach in inactive form as prorennin and then activated to Rennin by HCI.
- 16. (a) Bile is secreted by liver and stored in gall bladder.
- (d) Pepsin initiates the digestion of protein in stomach producing proteoses and peptones.
- (c) Pancreatic lipase (formely called steapsin) hydrolyses fats into glycerol and fatty acids.
- 21. (b) Stored glycogen is broken down to glucose under the effect of glucagons secreted by alpha cells of Islets of Langerhans.

- 25. (d) Gastrin is a polypeptide hormone secreted by the pyloric mucosa which stimulates the stomach to release gastric juice.
- 26. (c) Cholecystokinin is a polypeptide hormone produced by the mucosa of the upper intestine which stimulates contraction of gall bladder.
- (d) Renin is the hormone secreted by JGA in kidney. It is released due to hypotention (low BP).
- (c) Trypsin an enzyme or enzyme complex is a part of pancreatic juice and is able to digest proteins in alkaline medium.
- **31.** (a) Insulin is produced by β cells of islets of Langerhans.
- **32.** (b) Enterokinase is a gastro–intestinal enzyme secreted by small intestine of vertebrate, which converts trypsinogen to trypsin.
- 37. (a) Secretin hormone produced by duodenal mucosa which causes a copious secretion of pancreatic juice.
- **38.** (a) Since amylase, rennin and trypsin are enzymes, therefore these all are proteins.
- **40.** (c) The duodenal epithelium is stimulated to secrete secretin by the entry of acidic chyme into the duodenum.
- **42.** (b) Succus entericus is the intestinal juice stimulated by secretin and cholecystokinin from the intestinal glands.
- 43. (c) It is a hormone secreted by the mucosa of small intestine.

Nutrition and Nutritional requirement

- (a) Marasmus occurs due to prolonged malnutrition and deficiency of proteins and calories.
- 4. (a) Retinal pigment is an aldehyde of vitamin A.
- 10. (c) Proteins are broken down into amino acids during the process of digestion and finally all fats are converted into fatty acid, glycerol and monoglycerides.
- (a) Proteins are made up of amino acid molecules, hence on hydrolysis they form amino acids.
- 14. (b) Carbohydrates are chief source of energy in the food of most of the animals. Main source of carbohydrates are cereals, fruits, milk rice, and potato.
- **16.** (b) Casein is protein which form the part of food for the young animal. Best source of casein is milk.
- 18. (b) Carbohydrate are classified as: Monosaccharides (e.g., glucose, fructose, galactose), disaccharides (e.g., sucrose, maltose, lactose) and polysaccharides (e.g., starches, glycogen, cellulose, dextrins).
- (c) Lactose (C₁₂H₂₂O₁₁) is milk sugar. It is a diasaccharide composed of glucose and galactose unit.
- 20. (b) The anhydrobonds of protein are called peptide bonds. A peptide bond is formed between carboxyl group of one amino acid and amino group of adjacent.
- 21. (b) Carbohydrates are more suitable for the production of energy in the body then proteins and fats. Carbohydrate are also stored in the body cells as glycogen and are used for the production of energy whenever required.

- 23. (c) Essential amino acids are those which are taken from food, not synthesized in the body.
- (d) Primary component of bones and also present in muscles and blood.
- 29. (a) Thiamine (B₁) deficiency is common in alcoholics. It leads to decreased mental function, double vision and reduced muscular contraction and the resulting disorder is known as Wernicke's syndrome.
- **30.** (a) Steen Hoeck described that vitamin D is synthesized in presence of UV rays of sunlight in the skin.
- 31. (b) The vitamins are generally divided into Two major groups: Fat soluble (A, D, E and K) and water soluble (B - complex and C)
- **32.** (d) Biotin or nicotinic acid consists of sulphur. It acts as coenzyme needed for protein and fatty acid synthesis, CO₂ fixation and transamination.
- **33.** (b) On the basis of their requirement in body the inorganic elements are of two types :
 - (i) Macroelements: C, H, N₂ and O₂ are called big four elements of living body because they are required in maximum amount in the body.
 - (ii) Microelements: Iron, iodine, manganese, copper, zinc, fluorine etc, are required in minimum amount in the body.
- 34. (d) Barium is not used in human body.

Calcium is useful in formation of bone teeth and helps in blood clotting. It keeps muscle and nerve activity normal. Phosphorus is important for formation of bone teeth and biomembranes. It keeps muscle and nerve activity normal. It is a part of energy carriers (ATP, ADP, AMT) nucleic acid (DNA and RNA) and coenzymes.

Zinc is a component of atleast 70 enzymes. It is also essential for vitamin A metabolism, healing of wounds and protein synthesis.

- (a) Vitamin C is also called anti scorbutic factor and Ascorbic acid.
- 42. (c) Vitamin C is heat labile.
- 44. (c) The term vitamin was given by Funk.
- 47. (b) Zinc takes part in immune reactions.
- **55.** (c) Deficiency of vitamin B_1 causes beri-beri disease. Beriberi disease was discovered by Eijkman in 1897.
- **60.** (b) Fluorine maintains normal dental enamel and prevents dental caries.
- **64.** (a) Vitamin A is synthesized in liver from yellow and red carotenoid pigments.
- 65. (c) The given symptoms occur due to deficiency of thiamine (vit. B₁). Thiamine is a precursor of the coenzyme thiamine pyrophosphate which functions in carbohydrate metabolism. Deficiency leads to beriberi in humans and to polyneuritis in birds. Good sources include brewer's yeast, wheat germ, beans, peas and green vegetables.

- 66. (b) Because vitamin K helps in maintenance of normal prothrombin and factor VII in the blood and thus takes part in normal coagulation.
- 69. (d) As both vitamin B₁₂ and folic acid are involved in maturation of erythrocytes in bone marrow.
- 75. (d) Vitamin E maintains normal functioning of reproductive organs hence it is called fertility vitamin. Sterility (impotence) and muscular atrophy is common deficiency disease of vitamin E.
- **79.** (c) Vitamin B_{12} is a dark red compound containing cobalt.
- 80. (d) Vitamin D also known as calciferol. The deficiency of calciferol causes, the children suffer from rickets and adult from osteomalacia.
- 81. (b) Vitamin A occurs in yellow vegetables and fruits like carrots, tomatoes, papaya and mango, green leafy vegetables as spinach.
- 84. (b) Vitamin B_{12} is not found in plants. However it is considered that spirulina (an algae) contain B_{12} . Vitamin B_{12} is synthesized by intestinal bacteria which infact are main source of vitamin B_{12} . Many microorganisms (bacteria) of the stomach of ruminant mammals also synthesize large quantities of vitamin B_{12} .
- (b) Vitamin E is also called as tocopherol or antifertility vitamin.
- 89. (c) Nicotinic acid or vitamin B₅ is a pellagra preventing factor or PP factor. Pellagra caused due to the deficiency of vitamin B₅ is characterized by dermatitis (thick, pigmented skin), muscle atrophy and severe inflammation of mucous membrane of mouth.
- 90. (c) Vitamin B₁₂ is also called cyanocobalamine. It is essential for the formation and maturation of erythrocytes.
- 98. (c) It increases the RBC count and the platelets through its action on the bone marrow. It promotes haemopoeisis.
- 100. (c) Vitamin B₁₇ has been recently explained to be found in water melon. It is supposed to have anti cancer property.
- 109. (b) Vitamin-C (Ascorbic acid) play an important role in certain metabolic reactions. This vitamin activates an enzyme that is involved in synthesis of hydroxy proline which is an integral part of collagen. Obviously it is essential for formation and growth of connective tissues cartilage, bone, teeth etc.
- **110.** (c) Since vitamin K helps in blood clotting, its deficiency will lead to excessive bleeding.
- 112. (c) Paralysis of muscle fatigue and burning feet syndrome is related with deficieny of pantothenic acid (vitamin B₃).
- 114. (c) In man, attached to caecum is a twisted, coiled tube, measuring about 3 inches in length, called the vermiform appendix. Inflamation of the vermiform appendix is called appendicitis.

- 115. (a) It takes part in the formation of coenzyme FMN and FAD.
- 116. (a) Nutrition or food intake in paramecium of nutrition in amoeba is holozoic that is, amoeba is heterotrophic.
- 119. (a) A young man requires approximately 3000K. cal. per day while a child of about 15 years requires 2500 and infant of 4-6 years requires about 1500 Kcal per day.
- 122. (b) It also maintains the integrity of epithelial tissue and prevents the infection.
- 124. (d) Vitamin C is necessary for formation of collagen fiber, in this way vitamin C helps for healing to the wound.
- **127.** (a) Vitamin A was discovered by Mc collum and Davis (1915) from butter and egg yolk.
- **129.** (c) The activity of vitamin *E* is destroyed by U.V. rays and oxidation.
- 130. (d) E.coli lives in mutual association in human colon as it obtains food from the intestine and in turn help to produce vitamin B_{12} .
- 133. (b) It acts as the coenzyme of pyruvate carboxylase. Its active factor is thymine pyrophosphate. It causes decarboxylation of pyruvic acid.
- **134.** (a) Beri-beri is caused by deficiency of vitamin B_1 (thiamine)
- 136. (a) The chemical name of vitamin B₁ is thiamine. It can be systhesized by bacteria inside the gut.
- **137.** (b) Because riboflavin is an orange-yellow compound, so cow's milk appears slightly yellowish.
- **139.** (c) Vitamin *K* (phylloquinone) is required for the formation of clotting factors by liver, thereby its deficiency leads to delay in coagulation i.e. haemorrhage.
- 141. (a) Proteins are large molecules of high molecular weight containing C, H, O and nitrogen (N). The presence of N distinguishes them from carbohydrate and fat. Iron, copper, iodine, sulphur and phosphorus may also be present in a very low proportion. Proteins are found in fish, meat, egg, wheat, bean, ground-nut and pulses.
- 143. (c) Lactose or milk sugar is a disaccharide formed by the union of one molecule of galactose and one molecule of glucose. Besides milk it is found in flowers of some plants
- 145. (c) Vegetable oil contains low molecular weight lipids.
- 146. (b) Copper takes part in haemoglobin synthesis.
- 147. (b) Primary anaemia is due to deficiency of Fe
- 148. (d) Amoeba takes solid food and digests it intracellularly.
- **150.** (d) Euglena carries on both autotrophic and hetrotrophic modes of nutrition.

Critical Thinking Questions

3. (c) The mucosa is highly folded and the single-layered mucous membrane of the infoldings forms tubular and often branched gastric gland in the lamina propria. Each gland has three types of secretory cells – neck cells, oxyntic cells, zymogen cells.

- 4. (d) Generally, fatty acids upto a chain length of 10 carbon atom are primarily absorbed through the blood capillaries, but those with higher chain length through lymphatic route (lymph vessels).
- 6. (b) The bile is a complex greenish and alkaline fluid. Containing bile salt and bile pigment. Most important bile pigment is bilirubin which is a breakdown product of hemoglobin, biliverdin is absent.
- 10. (d) Odour of faeces is due to presence of toxic amines indole and skatole derived from action of bacteria on amino acid. Gases also causes odour in faeces. They are produced by fermentation of carbohydrate.
- 11. (a) A lipoprotein is a biochemical assembly that contains both proteins and lipids. There are several types of lipoproteins, each having different functions, but all essentially are transport vehicles. Lipoproteins are categorized and named mainly accordingly to their density which varies with the ratio of lipids to proteins from largest and highest to smallest and heaviest, the four major classes of lipoproteins are chylomicrone, VLDL, LDL and HDLs.
- (a) Caecum is small blind sac which host some symbiotic micro-organism.
- (d) Enterogastrone is secreted by the duodenal epithelium.
 It inhibits gastric secretion and motality.
- (c) Well established gastrointestinal hormones are i. secretin, ii. CCK, iii. Gastrin, iv. GIP, v. Motilin.
- 16. (c) Enterocrinin is secreted by the epithelium of entire small intestine. It stimulates the crypts of lieberkuhn to release enzymes it to the intestinal juice.
- 18. (a) Third molars in human being are called wisdom teeth. Number of 3rd molar in both jaw is four.
- 20. (c) Glycogen is a branched polymer of glucose. It is stored mostly in muscles and liver of animal and it is also called animal starch.
- (b) In the presence of enterokinase, inactive trypsinogen is converted into active trypsin.
- 23. (d) Vitamin K is also known as antihaemorrhagic vitamin.
- 26. (b) Vitamin C promote wound healing.
- **27.** (d) Pellagra is a disease caused by the deficiency of nicotinamide or nicotinic acid or niacin or vitamin B_5 . It is frequent among people eating food with low tryptophan content. The symptoms of pellagra are inflammation of skin, diarrhoea and dementia.
- 28. (a) Riboflavin (vitamin B_2) causes cheilosis, which is characterized by inflammation and cracking at the angles of the mouth.
- 30. (a) Triglyceride molecule is completely hydrolyzed into three molecules of fatty acid + one molecule of glycerol.
- 32. (d) Kwashiorkor is caused by the deficiency of proteins in diet this disease occurs in children of age group 1 to 5 years.

- **33.** (b) Intestinal villi are mainly concerned with absorption. Villi are absent in stomach.
- 34. (c) Empty stomach is lined with folds called rugae.
- 35. (d) Auerbach's plexus is a part of autonomic nervous system in vertebrates lying between the two main muscular layers of intestine and controlling its peristaltic movements.
- 38. (d) Digestion in human is extracellular (intercellular).
- **40.** (b) The entire small intestine has circular folds of the mucous membrane, the 'valves' of kerkring. These folds are more prominent in the jejunum.
- 42. (c) The blood carries from digestive tract to liver through hepatic portal vein the blood which comes from the digestive tract contains absorbed food like glucose and amino acids.
- **43.** (a) Glucose and galactose are absorbed by active transport. Fructose is absorbed by facilitated diffusion.
- 46. (d) Physiological value of carbohydrates is 4.0 kcal/g of proteins 4.0 kcal/g and of fats is 9.0 kcal/g
 Hence
 5 g raw sugar will yield 5×4.0 = 20.0 kcal
 4 g albumin (protein) will yield 4×4.0 = 16.0 kcal
 10 + 2 g of fat will yield 12×9.0 = 108.0 kcal
 Total yield = 144 kcal.
- **49.** (c) Pituitary gland is located in bony depression called sella turcica in sphenoid bone of cranium.

Assertion and Reason

- (a) In liver, glycogen a reserve food material is changed into glucose (glycogenolysis) and released into blood. Under abnormal conditions, liver can convert proteins and fats into glucose by complex chemical reactions i.e., called gluconeogenesis. Thus, due to hepatectomy blood sugar level falls rapidly.
- 2. (d) Fatty acids which lack any double or triple bond in their hydrocarbon chain are known as saturated fatty acids. Example lauric acid, arachidic acid, myristic acid, palmitic acid, stearic acid etc in contrast to saturated fatty acids, unsaturated fatty acids have one or more double bonds between carbon atoms at fixed place along the hydrocarbon chain. Example palmitoleic acid, oleic acid, linoleic acid, linolenic acid, arachidonic acid etc.
- and camel have a compound stomach, which consists of four chamber, viz, rumen, reticulum, omasum and abomasum. Rumen is the first and the largest of the four chambers. Rumen and reticulum harbour numerous bacteria and protozoa, which carry out extensive fermentation of cellulose. So, these two chambers function as sites for cellulose digestion in ruminants. The gastric juice containing enzymes and HCl is secreted only by the fourth chamber i.e., Abomasum.

- 4. (c) Numerous tube like glands are present in the wall of small intestine which secrete intestinal juice into the intestinal lumen. This juice contains a number of like enterokinase, aminopeptidases. dipeptidases, maltase, lactase, lipase etc. for digesting various types of food. On the other hand, the enzymes RNAse and DNAse are present in the pancreatic juice. These enzymes are secreted by the pancreas and are drained into the small intestine via Hepato pancreatic
- 5. (d) Minerals take part in biological reactions and are thus biologically active. Anaemia is caused by deficiency of
- (a) Thick layer of muscles are present in the alimentary canal. These muscles facilitate the movement of food particles through alimentary canal. Large food particles are broken down into small, semi liquid particles by the action of these muscles. Later also help in the forward flow of food materials and mixing of enzymes coming from different glands related to alimentary canal.
- (e) Alcoholic fermentation is the respiration in absence of 7. O2. In this process, hexose molecule is changed to ethyl alcohol and CO2. In presence of zymase enzyme. In this less amount of energy is released as compared to aerobic respiration.
- (e) Insulin is secreted by β -cells of islets of Langerhans. It 8. helps in conversion of glucose into glycogen decreasing blood sugar level. This is called glycogenesis.
- (b) Carbohydrates are more suitable for the production of energy in the body than proteins and fats, because carbohydrate molecules contain relatively more oxygen than the others, and consequently, requires less molecules of oxygen for their oxidation. In other words, for each litre of oxygen consumed, carbohydrates yield far more energy than proteins or fats. Carbohydrates are also stored in the tissue as glycogen for use in the production of energy, when necessary. Glycogen is the stored fuel particularly in such tissues as skeletal muscles which then have to work with a supply of oxygen far lower than their immediate need.
- 10. (c) Non essential amino acids are those amino acids which need not be supplied in the diet because they can be synthesised by the body, particularly from carbohydrate metabolites, Glycine is one such non essential amino acid. On the contrary, essential amino acids are those amino acids which can not be synthesised in the animal body and must be supplied with food in adequate amounts. Out of twenty amino acids, eight are considered essential in human diet.
- (a) Ascorbic acid is called vitamin C. The deficiency of this vitamin causes scurvy.

- (c) In small intestine Pancreatic amylase converts starch and dextrins into maltoses and small intestine is main site for digestion of carbohydrates.
- (d) In liver, alcohol is oxidised into acetaldehyde which is 13. further oxidised into acetate. The latter is converted to acetyl coenzyme A which is used in Krebs' cycle. Ethyl alcohol → Acetaldehyde → Acetate → Acetyl Co $A \rightarrow CO_2 + H_2O$
- 14. (a) The human being is the only mammal who ingests significant amount of lactose in milk. Curiously, many human adults can not digest milk, because with age they produce little or no lactose in the intestinal juice. In such persons, the lactose of milk remains undigested and is fermented in the intestine producing gases and acids. This results in flatulence, intestinal cramps and diarrhoea.

Adult human 1

Less or no lactase

Lactose remains undigested

Undigested substances fermented

1

Produce gas, acids, intestinal cramps, diarrhoea

- (a) Trypsin is protein digesting enzyme present in the intestine of animals. Though it cannot digest casein (a milk protein), in predator animals drinking the blood of their prey, trypsin hydrolyses fibrinogen of blood into fibrin, leading to blood coagulation thus help in blood digestion. It also activates other pancreatic proteases.
- 16. (a) If sea water is drunk, its Mg^{2+} ions increase the solute concentration in the intestinal lumen because Mg2+ is absorbed very slowly. On the contrary, Mg2+ draws water from the blood to the intestinal lumen by osmosis. So, water is not gained, but is lost from the blood on drinking sea water. Thus, there occurs increase in the fluidity and volume of intestinal contents, in the same way this consequently stimulates intestinal peristalsis and evacuation of fluid faeces.
- 17. (a) Sea faring fisherman suffer from paralysis because raw fish muscles contain an enzyme which destroys Vitamin B1.
- 18. (d) Starch is hydrolysed by pancreatic amylase to maltose, isomaltose and dextrins sucrose - sucrase glucose and fructose.
- 19. (b) The body temperature in cold blooded varies with that of the environment as there is no fat deposition. On the other hand, cold blooded animals use fat during hibernation to carry out their metabolic processes.
- 20. (e) Absorption takes place in small intestine as it offers large surface area for absorption. Stomach produces the hormone gastrin and intrinsic factor.

FT Self Evaluation Test

- [Kerala PMT 2007] Find out the correctly matched pair
 - (a) Pepsinogen
- Zymogenic cells

(b) HCI

- Globlet cells
- (c) Mucous
- Oxyntic cells
- (d) Pancreatic juice
- Salivary glands
- (e) Ptyalin
- Acinar cells
- A dental disease characterized by mottling of teeth is due to the excess of a certain chemical element in drinking water. [BHU 2000] Which of the following is that element
 - (a) Mercury
- (b) Chlorine
- (c) Fluorine
- (d) Boron
- 3.
- Spot the salivary gland among the following **IKCET 19991**
 - (a) Sublingual
- (b) Adrenal
- (c) Brunner
- (d) Lacrymal
- Excess carbohydrates and proteins are stored in the body as [DUMET 2010]
 - (a) Amino acids
- (b) Fats
- (c) Starch
- (d) Monosaccharide
- The colour of the faeces is due to the 5.
 - (a) Urochrome
- (b) Stercobilin
- (c) Biliverdin
- (d) Bacteria
- Which one is detritus feeder
 - (b) Sheep
- (a) Parrot (c) Unio
- (d) Dung beetle
- 7. Lamina propria is related with
 - (a) Human intestine
- (b) Liver of human being

[RPMT 2000]

- (c) Graafian follicle
- (d) Acinus of pancreas
- How many teeth in man grows twice in life 8.
 - [JIPMER 2001; AFMC 2002, 04]
 - (a) 32

(b) 28

(c) 20

- (d) 12
- 9. Find out the correct match

	Column – I		Column – II	
A.	Hepatic lobule	1.	Sub mucosal glands	
B.	Brunner's glands			
C.	Crypts of Lieberkuhn	3.	Glisson's capsule	
D.	Sphincter of Oddi	4.	Gallbladder	
E.	Cystic duct	5.	Hepato- pancreatic duct	
		6.	Serous glands	

[NCERT; Kerala PMT 2007; J & K CET 2008]

- (a) A-3, B-6, C-2, D-5, E-4
- (b) A-5, B-2, C-3, D-6, E-1
- (c) A-3, B-1, C-2, D-5, E-4
- (d) A-4, B-6, C-5, D-2, E-1
- (e) A-4, B-2, C-6, D-5, E-3
- By the mechanical stimulation on the wall of stomach, a 10. hormone is released. This is
 - (a) Gastrin
- (b) Progesterone
- (c) Secretin
- (d) Pancreozymin
- Insulin, epinephrine, glucagon collectively influence
 - (a) Glyconeogenesis
 - (b) Glycerophosphate shuttle
 - (c) Glycolysis
 - (d) Glycogenolysis and glycogenesis

Match the item in Column I (vitamins) with those in Column II (deficiency diseases)

Column II Column I (Vitamins) (Diseases)

- K I. II.
- D
- III. IV. A
- A. Beri-beri Haemorrhagic disease in
- new born Night blindness

 - D. Rickets
- Which one of the following is the correct matching of all the four vitamins

[CBSE PMT 1995; MP PMT 1999, 2002; DPMT 2006]

- (a) I-C, II-B, III-D, IV-A (b) I-A, II-B, III-D, IV-C
- (c) I-C, II-A, III-D, IV-B (d) I-B, II-D, III-A, IV-C
- Pernicious anaemia is caused due to the deficiency of 13.

[MP PMT 2009; WB JEE 2009]

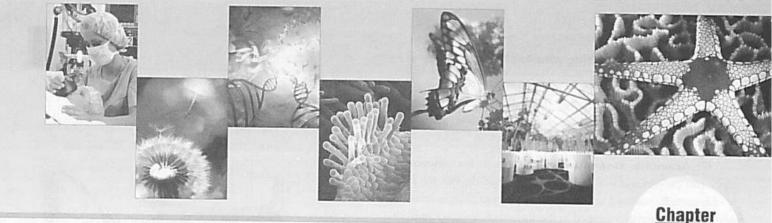

This vitamin is also known as "Castle's extrinsic factor"

- (a) Folic acid
- (b) Vitamin B_6
- (c) Vitamin B₁₂
- (d) Appendix
- [Odisha JEE 2011] 14. Exclusive holozoic nutrition is seen in
 - (a) Spider
- (b) Man
- (c) Housefly
- (d) Shark
- Symbiotic bacteria present in intestine of most primates, 15. which synthesize certain vitamins are
 - (a) Entamoeba histolytica
 - (b) Entamoeba coli
 - Entamoeba gingivalis
 - None of these

Answers and Solutions

1	a	2	С	3	a	4	b	5	b
6	С	7	a	8	C	9	С	10	a
11	d	12	d	13	С	14	b	15	b

- (c) Excess intake of fluorine causes fluorosis, which is 2. manifested in its mild state by mottled teeth and in a more severe state by enlarged bones.
- In human, 3 pairs of salivary glands are present. They 3. are sublingual, parotid and submaxillary.
- 5. It is an oxidation product of bile pigment.
- Animal which feeds upon organic matter mixed with the 6. soil e.g. earthworm and unio.
- (c) In man, 20 teeth are diphyodont, i.e., grow twice in life. 8.
- (d) Epinephrine and glucagon cause glycogenolysis while 11. insulin causes glycogenesis.
- Pernicious anaemia marked by a decrease in the 13. number of red blood cells which is caused by a reduced ability to absorb vitamin B_{12} .
- Escherichia coli is common colon bacteria found in 15. human beings and many vertebrates. This bacteria is normally not harmful but is mostly helpful in digestion through synthesis of vitamin.

Chapter

5.2

Breathing and Exchange of Gases

Cells continually use oxygen (O_2) for the metabolic reactions that release energy from nutrient molecules and produce ATP (Adenosine Tri Phosphate). At the same time, these reactions release carbon dioxide. Since an exce amount of CO_2 produces acidity that is toxic to cells, the excess CO_2 must be eliminated quickly and efficiently. The two systems that cooperate to supply O_2 and eliminate CO_2 are the cardiovascular system and the respiratory system. The respiratory system provides for gas exchange, intake of O_2 and elimination of CO_2 , whereas the cardiovascular system transports the gases in the blood between the lungs and body cells.

Respiration

Respiration is a process which involves intake of oxygen from environment and deliver it to the cells. It include stepwise oxidation of food in cells with incoming oxygen, elimination of CO_2 produced in oxidation, release of energy during oxidation and storing it in the form of ATP. It takes place in three basic steps –

- (1) Pulmonary ventilation: The first process, pulmonary (pulmo = lung) ventilation, or breathing, is the inspiration (inflow) and expiration (outflow) of air between the atmosphere and the lungs.
- (2) **External (pulmonary) respiration**: This is the exchange of gases between the air spaces of the lungs and blood in pulmonary capillaries. The blood gains O_2 and loses CO_2 .
- (3) Internal (tissue) respiration: The exchange of gases between blood in systemic capillaries and tissue cells is known as internal (tissue) respiration. The blood loses O_2 and gains CO_2 . Within cells, the metabolic reactions that consume O_2 and give off CO_2 during production of ATP are termed cellular respiration.

Respiratory surface

The surface at which exchange of gases (CO_2 and O_2) takes place is called respiratory surface. Respiratory surface must be

vascular and have enough area for gas exchange. For example – plasma membrane in protozoa, body wall (skin) in annelids, alveocapillary membrane in men.

Respiratory medium

Oxygen is dissolved in air and water. Thus water and air are source of oxygen for animals and called respiratory medium. Water and air are external respiratory medium. Inside the body an internal respiratory medium is also found. This internal respiratory medium is tissue fluid.

Types of respiration: It is of two types

(1) Aerobic respiration: It occurs in the presence of molecular oxygen. The oxygen completely oxidizes the food into carbon dioxide and water, releasing large amount of energy. The organisms showing aerobic respiration, are called aerobes. It is found in most of animals and plants. Aerobic respiration is of two main types direct and indirect.

$$\begin{array}{c} C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O + 2830\, kJ \\ \text{Glucose} & \text{oxygen} \end{array} \rightarrow \begin{array}{c} 6CO_2 + 6H_2O + 2830\, kJ \\ \text{Energy} \end{array}$$

- (i) Direct respiration: It is the exchange of environmental oxygen with the carbon dioxide of the body cells without special respiratory organs and without the aid of blood. It is found in aerobic bacteria, protists, plants, sponges, coelenterates, flatworms, roundworms and most arthropods.
- (ii) Indirect respiration: It involves special respiratory organs, such as skin, buccopharyngeal lining, gills and lungs, and needs the help of blood. The respiration in the skin, buccopharyngeal lining, gills and lungs is respectively called cutaneous buccopharyngeal, bronchial and pulmonary respiration. Cutaneous respiration takes place in annelids, some crustaceans, eel fish, amphibians and marine snakes. It occurs both in water and in air. Buccopharyngeal respiration is found in certain amphibians such as frog and toad. It occurs in the air. Bronchial respiration is found in many annelids, most crustaceans and

molluscs, some insect larvae, echinoderms, all fishes and some amphibians. It occurs in water only. Pulmonary respiration is found in snails, pila, some amphibians and in all reptiles, birds and mammals. It takes place in air only.

(2) Anaerobic respiration: It occurs in the absence of molecular oxygen and is also called fermentation. In this, the food is only partially oxidised so only a part of energy (5%) is released and of energy remains trapped in the intermediate compounds. It is found in lower organisms like bacteria and yeast. It is also found in certain parasitic worms (Ascaris, Taenia) which live in deficient medium. The organism showing anaerobic respiration, are called anaerobes. These involve one of following reactions.

$$\begin{array}{c} C_{6}H_{12}O_{6} \xrightarrow{\text{In yeasts}} 2C_{2}H_{5}OH + 2CO_{2} + 118\,\text{kJ} \\ \text{Ethanol} \end{array}$$

$$\begin{array}{c} C_{6}H_{12}O_{6} \xrightarrow{\text{In intestinal worms}} 2CH_{3}CHOHCOOH + \text{Energy} \\ \text{Glucose} \end{array}$$

Certain body tissues of even aerobes also show anaerobic metabolism e.g., during the vigorous contraction of skeletal muscle fibres. In this, the glucose is metabolised into the lactic acid in anaerobic conditions. The rapid formation and accumulation of lactic acid are responsible for muscle-fatigue. The mammalian RBCs shows anaerobic respiration as these lack the mitochondria. In lens of eye and cornea of eye respiration is anaerobic because these structures are non vascular. Anaerobic respiration appeared first in primitive organisms because there was absence of O_2 in primitive atmosphere.

Respiratory organs

- (1) **Skin**: Respiration by skin is called cutaneous respiration. Skin is the only respiratory organ in most annelids (earthworm and leeches) and an additional respiratory organ in amphibians (Toads and frogs). Skin should be thin, moist, naked, permeable and well vascular for respiration. For cutaneous respiration animal should have large surface area then its volume and should have relatively inactive life to minimize the use of oxygen. Some marine annelids such as sandworms (nereis) have parapodia (locomotory appendages) for respiration. In frog 100% cutaneous respiration during hibernation. In all marine snakes 20% respiration by skin.
- (2) **Tracheae**: In insects, peripatus centipedes and millipedes tracheae are found for respiration. Tracheae are complex system of whitish, shining, intercommunicating air tubules. Tracheae are ectodermal air tubes. In cockroaches, three pairs of longitudinal tracheal trunks are present all along the length of body which are further connected with each other with the help of transverse branches. The main tracheae give off smaller tracheae whose branch repeatedly form a network of trachioles throughout the body. Trachea internally lined by chitinous cuticle called intima, which spirally thickened to form taenidae. Trachioles without taenidae, trachioles lined by trachein protein. From each tracheal trunk three branches come out. The dorsal branch is supplied to

the dorsal muscles where as ventral one to nerve cord and ventral muscles and middle one to the alimentary canal.

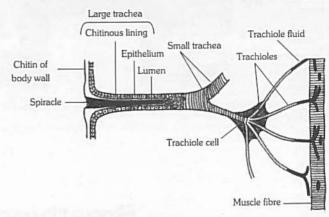

Fig: 5.2-1 Trachea of cockroach

- (3) Book lungs and book gills: Spiders ticks, mites and scorpion (belongs to class arachnida) have book lungs for respiration. In scorpion 4 pairs of book lungs are present. A book lung is a chamber containing a series of thin vascular, parallel lamellae arranged like the pages of book. Book gills are found in marine king crab or horse shoe crab.
- (4) **Gills**: Aquatic animals such as prawn, unio, fishes, sea stars and tadpoles respire by gills. Respiration by gills called bronchial respiration. Gills are of two types –
- (i) External gills: External gills are found in arenicola (lug worm), larvae of certain insects e.g. damsel fly and some amphibians e.g. necturus, siren, proteus, frog tadpole first develop external gills which are replaced by internal gills later.
- (ii) **Internal gills :** The internal gills may be phyllobranch (prawn), monopectinata (pila) eulamellibrach (unio), lamellibranch, fillibranch (pisces). In all fishes, gills are hemibranch or demibranch and holobranch. In gills, gill lamellae are found which have capillary network. Water is drawn into gills \rightarrow blood flowing in the capillaries of gill lamellae absorb oxygen from water and release $CO_2 \rightarrow$ water containing CO_2 is thrown out from gills. The 80% of O_2 of incoming water is absorbed.

Table: 5.2-1 Oxygen content of respiratory media

Respiratory media	Oxygen content	
Air	209.5 ml./l.	
Fresh water at 25°C	5.8 ml./l.	
Fresh water at 5°C	9.0 ml./l.	
Sea water at 5°C	6.4 ml./l.	

(5) **Buccopharyngeal lining**: Frog breathes by buccopharyngeal lining of buccopharyngeal cavity. This is called buccopharyngeal respiration.

UNIVERSAL BOOK DEPOT 1960

Table: 5.2-2 Respiratory organs of animals

Animals	Respiratory organs			
Protists, Bacteria	Direct respiration through plasma membrane			
Porifera	Plasma membrane of each cell			
Coelenterates	General body surface			
Platyhelminthes (Fasciola hepatica, tapeworm)	Anaerobic			
Nematodes (Ascaris)	Anaerobic			
Annelids (Earthworm and Leeches)	Skin			
Nereis	Parapodia			
Insects	Trachea			
Centipedes	Trachea			
Millipedes	Trachea			
Spider and Scorpion, ticks, mites	Book lungs			
Marine king crab	Book gills			
Prawns, Unio and Pila	Gills			
Echinodermata	Dermal branchiae, Tube feet, Respiratory tree, Bursae			
Fishes, Tadpoles	Gills			
Frogs, Toads	Buccopharyngeal lining, Lungs, Skin			
Reptiles, Mammals	Lungs			
Birds	Air sacs/Lungs			
Lung fish	Air bladder.			
Urochordata (Herdmania)	Test			
Marine turtle	Clocal respiration			
Mollusca (Unio)	Mental			

Respiratory system of human

Human respiratory system is derived from endoderm. Human respiratory system may be divided into two components –

- (1) Respiratory tract or conducting portion
- (2) Respiratory organs
- (1) Respiratory tract or conducting portion: It is the passage for the air. In this part gaseous exchange does not takes place. It is also called dead air space. It is divided in following parts —
- (i) Nose (Latin-Nasa) (Greek-Rhine): Cavity of nose is called nasal cavity. Nasal cavity is divided into two parts by nasal septum called mesethmoid. Each part is called nasal chamber. Each nasal chamber opens out side by external nares. Nasal septum has two part. First part is small and is made of cartilage (hyaline). Second part is major and it is bony. Vomer is the main bone. Each nasal chamber has three region.
- (a) Vestibular region: Vestibular region also known as vestibule is lined by non keratinized squamous epithelium, it is ectodermal in origin and have sebaceous gland, sweat gland and hair. Vestibule is also found in inner air larynx, mouth and vagina. It acts like a seive to check the entry of large dust particles and other things.
- (b) Respiratory region: Middle region lined by respiratory epithelium which is ciliated pseudostratified columnar epithelium. It contains mucus and serous cells. Mucus cells produce mucus and serous cells produce watery fluid. Respiratory epithelium is highly vascular and appears pink or reddish. Respiratory region acts as a

air conditioner and makes the temperature of in going air nearly equal to body. It also acts as a filter not give entry to dust particles, flies or mosquitoes.

- (c) Olfactory region: It is upper region. It is lined by olfactory epithelium. This is also called Schneiderian epithelium. Olfactory region is the organ of smell and detect the odour of inspired air. Inspiration is stopped if odour of air is foul or offensive. According to new researches pheromone receptors are found in nasal cavities.
- (ii) Nasal conchae: Lateral wall of nasal cavity have three shelves like structures called conchae or turbinate. 3 pairs of nasal conchae are found. Nasal conchae are covered with mucus membrane. They increase the surface of nasal chamber. Both the chambers of nasal cavity open into nasopharynx by their apertures called internal nostrils or conchae. Adjacent to internal nostril there are opening of eustachian tube. Names of these three conchae and names of the bones that form them are given below.
- (a) **Superior conchae**: The dorsal most chochae is supported mainly by nasal bone called nasoturbinate. It is the smallest conchae.
 - (b) Middle conchae: Ethmoid bone called ethmoturbinate.
- (c) Inferior conchae: The ventral most conchae supported by maxilla bone called maxilloturbinate. It is a separate bone itself.
- (iii) **Pharynx**: It is the short vertical about 12 cm long tube. The food and air passages cross here. It can be divided in 3 parts –
- (a) Nasopharynx: Nasopharynx is only respiratory upper part in which internal nares open. There are 5 opening in its wall; two internal nares, two eustachian tube opening and one opening into oropharynx.
- (b) Oropharynx: Middle part is called oropharynx. In this part oral cavity open known as fauces. Two pair tonsils the palatine and lingual tonsils are found in the oropharynx.
- (c) Laryngopharynx or hypopharynx: Lowest part is called laryngopharynx. It leads into two tubes. One at the front is wind pipe or trachea and one at the back is food pipe or oesophagus. Both oro and laryngo pharynx is both a respiratory and a digestive pathway.

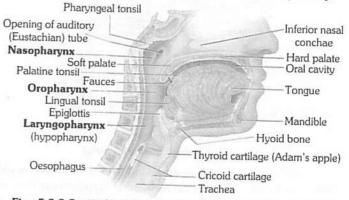

Fig: 5.2-2 Sagittal section showing the regions of the pharynx

Nasopharynx is lined by ciliated pseudostratified epithelia, oropharynx and laryngopharynx are lined by non keratinized epithelium. Pharynx is lined by non keratinized stratified squamus epithelium. This epithelium is cillieted in nasopharynx. Mouth serves as an alternate route for air when nasal chambers are blocked. Foramen by which pharynx opens into larynx called

glottis. In general it remains open. During swallowing it is closed. It provides passage for air. Pharynx leads into the oesophagus through an aperture called gullet. In general condition it remains closed and opens at the time of swallowing. During swallowing epiglottis closes the glottis.

(iv) Larynx or Voice box: It is found both in frogs and rabbits. Larynx does not help in respiration. It is present on tip of trachea and is made up of 9 cartilages such as thyroid (single) has a prominence called pomum admi or adam's apple, cricoid (single), arytenoid (paired), are piece of hyaline cartilage. While epiglottis (single), carniculate (paired), cuneiform (paired), santorini are piece of elastic cartilage. Clinically, the cricoid cartilage is the landmark for making an emergency air way.

Larynx is a short tubular chamber and opens into the laryngopharynx by a slit like aperture called glottis. Glottis always remains open except during swallowing. Larynx is more prominent in men than women due to male hormone. Before puberty, the larynx is inconspicuous and similar in both sexes. Larynx is a voice producing instrument. For this purpose larynx have two types of vocal cord. In birds voice producing organ is syrinx, found at lower end of tracheae.

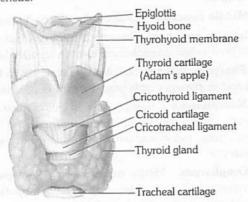

Fig: 5.2-3 Larynx (Anterior view)

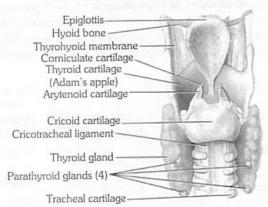

Fig: 5.2-4 Larynx (Posterior view)

- (a) False vocal cord or vibrating fold or anterior vocal cord: These are folds of mucus membrane. Gap between them is called rema vestibuli. These are not responsible for sound production. In elephants only true vocal cords are present and are responsible for this trumpet sound.
- (b) True vocal cord or posterior vocal cords: They are made up of yellow elastic fibres. Gap between them is called rema glottides or peep hole. In males the length of true vocal cord is 2.25 cm and in female is 1.75 cm. Sound produced by rabbit is called

quaking. Hippopotamus lacks true vocal cords. Pitch is controlled by the tension of vocal folds.

Fig: 5.2-5 Movement of vocal folds apart (abduction)

Fig: 5.2-6 Movement of vocal folds together (adduction)

(v) **Trachea**: It is a tubular structure of about 12 cm. in length and 2.5 cm in diameter. The wall of trachea is made of fibres, cartilage muscles and the mucus membrane. In middle of thorax at the level of 4th and 5th thoracic vertebra divides it into two branches called right and left primary bronchi. Further division of primary bronchi is given in form of arrow diagram.

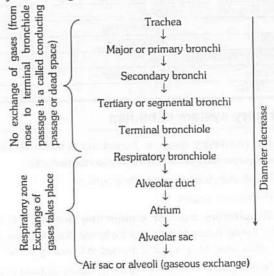

Table: 5.2-3 Different epithelium lining in respiratory tract

Vestibular region of nose	Skin having hair		
Respiratory region of nose	Ciliated pseudostratified		
Olfactory region of nose	Olfactory (Schneiderian) epithelium		
Pharynx (Oropharynx, Laryngopharynx)	Non-keratinised stratified squamous		
Trachea and bronchi (Upper)	Pseudostratified ciliated columnar epithelium with mucus cells		
Lower bronchi (Secondary / Tertiary)	Lined by simple ciliated columnar epithelia		
Terminal bronchioles and beginning of respiratory bronchiole	Simple ciliated columnar epithelium without mucus cells		
Rest of respiratory bronchioles, alveolar duct	Non ciliated cuboidal epithelium		
Alveoli	Non ciliated squamous		
Alveoli of frog's lungs	Columnar ciliated epithelium		

UNIVERSAL BOOK DEPOT 1960

Three special types cell are found in Bronchioles epithelium :

- (a) Kultchitsky cells or argentaffin cells: They secrete serotonin and histamine. Histamine dilate while serotonin constrict the bronchioles.
- (b) Clara cells: They secrete a phospholipid named diapalmityl lecithin which acts as a surfactant. This surfactant prevents the collapse of bronchioles lacking cartilagenous rings. Collapsing of lungs is called atelectesis. Pottle in 1956 proved the existence of surfactant. Surfactant is formed by clara cells only at later stage of foetal life. Some times at birth some infants are devoid of surfactant so there is great respiratory difficulty because lungs refuse to expand. In this condition death may occur. This is called respiratory distress syndrome (RDS) or hyaline membrane disease (HMD) or glassy lung disease.
- (c) Dust cells: They are phagocytes which eat foreign particles (dust).

Respiratory organs

In men the respiratory organ are a pair of lung. Some snakes have unpaired lungs. Respiration by lungs is called pulmonary respiration. Lungs are found in all vertebrates except fishes. In fishes such as protopterus, neoceratodus and lepidosiren air bladder is found, which is modified lung. Respiration in men and rabbit is pulmonary.

Lungs: Lungs lie in thoracic cavity on both side of heart in mediasternum space. Base of lung is attached to diaphragm. Right lung is divided into 3 lobes viz. Superior, Middle, Inferior and left lung is divided into two lobes Superior and Inferior. In rabbit, the left lung is divided into two lobes left anterior and left posterior where as the right lung has four lobes anterior azygous, right anterior, right posterior and posterior azygous. Lungs of reptiles are more complex than those of amphibians. In birds lungs are supplemented by elastic air sacs which increase respiratory efficiency. The narrow superior portion of lung is termed the apex or cupula.

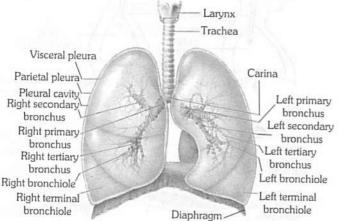

Fig: 5.2-7 Branching of airway from the trachea: the bronchial tree (Anterior view)

Each lung is enclosed in two membrane called pleura. Pleura are layers of peritoneum of thorax. Inner membrane is called the visceral pleuron. It is firmly bound to surface of lungs. The outer membrane is called parietal pleuron. It is attached to chest wall or wall of thoracic cavity. A narrow space exists between the two pleura. It is called pleural cavity. In pleural cavity a watery fluid is

found called pleural fluid. Pleural fluid is glycoprotein in nature and secreted by pleura. Pleural fluid lubricate the pleura so that they may slide over each other without friction. This fluids reduces friction between the membrane. When the lungs expand and contract in respiration. Pressure inside pleural cavity is negative – 5 mm Hg. Pleurisy is inflamation of pleura and cause collection of fluid in pleural cavity. It results painful breathing (dyspnea). The surface of lung lying against the ribs, known as coastal surface. The mediastinal (medial) surface of each lung contains a region – the hilus, through which bronchi, pulmonary blood vessels, lymphatic vessels and nerve enter and exit.

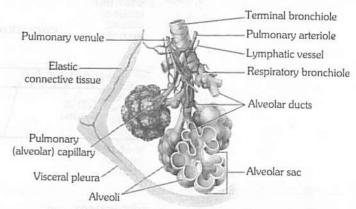

Fig: 5.2-8 Diagram of a portion of a lobule of the lung

Pulmonary volumes and capacities

The apparatus commonly used to measure the volume of air exchanged during breathing and the rate of ventilation is a spirometer (spiro=breathe) or respirometer. The record is called a spirogram. There are 4 respiratory volumes and capacity.

Respiratory volumes

- (1) **Tidal volume (TV)**: Volume of air inspired or expired in relaxed or resting position 500 *ml*. It consists of 150 *ml* of dead space volume and 350 *ml* of alveolar volume.
- (2) Inspiratory reserve volume (IRV): By taking a very deep breath, you can inspire a good deal more than 500 ml. This additional inhaled air, called IRV is about 3000 ml.
- (3) Expiratory reserve volume (ERV): If you inhale normally & then exhale as forcibly as possible, you should be able to push out 1100 ml. of air in addition to 500 ml. of T.V. The extra 1100 ml. is called ERV.
- (4) Residual volume (RV): Even after expiratory reserve volume is expelled, considerable air remains in the lung, this volume, which can not be measured by spirometry, it is called residual volume is about 1200 rnl.
- (5) Dead space: Portion of tracheobronchial tree where gaseous exchange does not occur called dead space. It is also called conductive zone. Dead space is 150 ml.
- (6) Functional residual capacity (FRC): It is the amount of air that remains in the lungs after a normal expiration. It is about 2300 ml.

$$FRC = ERV + RV$$

= 1100 + 1200 = 2300 ml.

(7) Vital capacity (VC): This is the maximum amount of air that can be expired forcefully from his lungs after first filling these with a maximum deep inspiration. It is about 4600 ml.

$$VC = IRV + TV + ERV$$

= $3000+500+1100 = 4600 \text{ ml.}$

(8) Total lung capacity (TLC): TLC is the sum of vital capacity (VC) and residual volume (RV). It is about 5800 ml.

TLC = VC + RV= 4600 + 1200 = 5800 ml.

(9) Inspiratory capacity (IC): It is the total amount of air a person can inspire by maximum distension of his lungs.

$$IC = TV + IRV$$

= 500 + 3000 = 3500 ml.

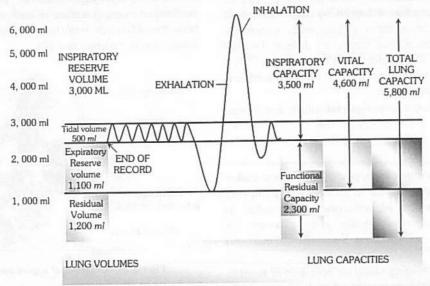

Fig: 5.2-9 Spirogram of lung volumes and capacities (average values for a healthy adult)

Process of Respiration

The process of respiration is completed in 4 steps -

- (1) Breathing or ventilation
- (2) Exchange of gases or External respiration
- (3) Transport of gases
- (4) Cellular respiration
- (1) **Breathing or ventilation:** Movement of thorax, expansion (inflation) and deflation of lungs and flow of air into the lungs and from the lungs. It is extracellular, energy consuming and physical process. Sum of inspiration and expiration is called respiratory movement. There are two steps of breathing –
- (i) Inspiration: Intake of fresh air in lungs from outside. It is an active process. Blood pressure increases during later part of respiration. Following muscles are involved in inspiration.
- (a) Diaphragm: Principle muscles of inspiration. It is a skeletal muscles attached to the sternum, vertebral column and ribs. It is formed by radial muscles fibres.

In relaxed condition it is dome shaped, convex towards thoracic cavity and concave towards abdominal cavity. During inspiration it contracts and become straight and descends down. This causes an increase in vertical diameter of thoracic cavity. Descent of diaphragm can explain about 75% of tidal air volume. 70% muscles fibres of diaphragm have some resistance to fatigue. Nerve which supply to diaphragm is phrenic nerve. Contribution of

diaphragm in breathing of full term pregnant lady is 0%. Most important function of diaphragm in mammals is to aid in inspiration. If diaphragm is punctured, respiration will stop and patient will die.

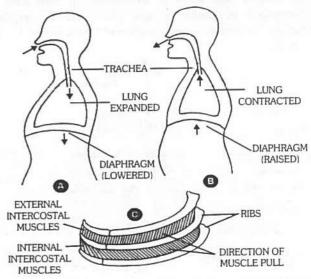

Fig: 5.2-10 Mechanism of breathing. A – Inspiration (Chest cavity enlarged) B – Expiration (Chest cavity reduced) C – Intercostal muscles

(b) External intercostal muscles: Gaps between the ribs are called intercostal spaces. They are filled by intercostal muscles. Intercostal muscles are of two types external intercostal muscles and internal intercostal muscles.

UNIVERSAL BOOK DEPOT 1950

External intercostal muscles are related to inspiration and internal intercostal muscles are related to expiration. Here we are concerned with external intercostal muscles. External intercostal muscles start from lower border of upper rib and comes to end outer lip of upper border of lower rib. Thus direction of external intercostal muscles fibres is downward forward. Contraction of external intercostal muscles causes increase in anteroposterior diameter of thoracic cavity and transverse diameter of thoracic cavity.

This two dimensional increase in diameter (i.e. anteroposterior and transverse) of thoracic cavity is due to special arrangement of ribs. This increase in thoracic cavity is assisted by diaphragm the most important muscle of inspiration. Contraction of diaphragm causes it to flatten lowering its dome. For simplification we can assume that each rib is attached anteriorly to sternum by its anterior end and posteriorly to vertebral column by its posterior end. Note these two points carefully —

- Anterior end of rib is lower than the posterior end.
- Middle portion of rib which is called shaft lies at lower level than the two end of rib (i.e. anterior and posterior)

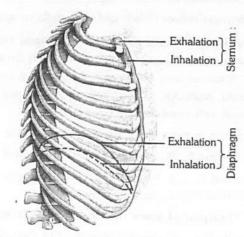

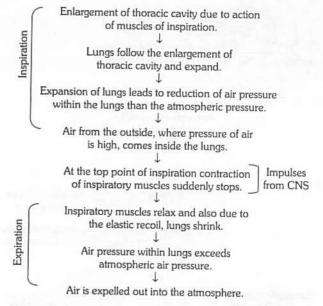

Fig: 5.2-11 Changes in size of thoracic cavity during inhalation and exhalation

- (c) Accessory muscles of inspiration: These muscles normally are not called into action but in forced inspiration they come into action. Accessory muscles are scaleni, sternomastoid and alae nasi.
- (ii) Expiration: Out flow of the air from the lungs is called expiration. When the inspiratory muscles relax, the external intercostal relax, ribs move inferiorly and as the diaphragm relaxes, its dome moves superiorly owing to its elasticity. These movements decrese vertical and anterior-posterior dimentions of thoracic cavity.
- (a) Internal intercostal muscles: Direction of fibres is backward and downward. Action is just opposite to external intercostal muscles. These muscles by their action reduces anteroposterior and transverse diameter of thoracic cavity.

(b) Abdominal muscles: Muscles of anterior abdominal wall. These muscles push the diaphragm up.

(iii) Mechanism of ventilation/breathing

(2) Exchange of gases

(i) Exchange of gases in lungs: It is also called external respiration. In this gaseous exchange oxygen passes from alveoli to pulmonary capillary blood and CO_2 , comes to alveoli from pulmonary capillary. In order to exchange the gases have to pass through alveolocapillary membrane or respiratory membrane. Composition of alveolocapillary membrane is epithelium lining of alveolar wall, epithelial basement membrane, a thin interstitial space, capillary basement membrane and capillary endothelial membrane.

Thickness of respiratory membrane is 0.5 μm . Respiratory membrane has a limit of gaseous exchange between alveoli and pulmonary blood. It is called diffusion capacity. Diffusion capacity is defined as volume of gas that diffuse through membrane per minute for a pressure difference of 1 mm Hg. Exchange of gases through alveolocapillary membrane is a purely physical diffusion phenomenon. No chemical reaction is involved. Diffusion of a gas depends upon pressure gradient across the membrane and solubility of gas.

Partial pressure: Partial pressure of a gas is the pressure it exerts in a mixture of gases, and is equal to the total pressure of the mixture divided by percentage of that gas in the mixture. For instance, if the pressure of atmospheric air at sea level is 760 mm. of mercury (Hg) and oxygen forms 21% of the air, the partial pressure of oxygen will be 21% of 760, or 159 mm. Hg. In other words, the partial pressure of a gas is proportional to its concentration in the mixture. Only about 0.3 ml. of O_2 can dissolve in 100 ml. of plasma, about 20 ml. of O_2 is carried by haemoglobin in 100 ml. of blood. In atmospheric air except these gases some traces of helium, argon and neon are also found.

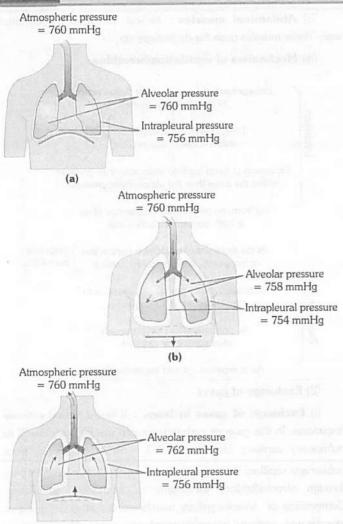

Fig: 5.2-12 Pressure changes in pulmonary ventilation; (a) At rest (diaphragm relaxed) (b) During inhalation (diaphragm contracting) (c) During exhalation (diaphragm relaxing)

Table: 5.2-4 Partial pressures of respiratory gases in mm. Hg

	III	mm. rig	21000 000 125 1100
Gas	Oxygen	Carbon dioxide	Nitrogen
Inspired air	158	0.3	596
Alveolar air	100-105	40	573
Venous blood	40	46	573
Arterial blood	95-100	40	573
Expired air	116	32	565
Tissue cells	20-40	45-52	

Table: 5.2-5 Composition of three samples of air

Gas	Oxygen	Carbon dioxide	Nitrogen	Water
Inspired air	20.84%	0.04%	78.62%	0.5%
Expired air	15.70%	4.00%	74.50%	6.2%
Alveolar air	13.6%	5.3%	74.9%	6.2%
Gain/loss %	Gain 5.14%	Loss 3.96%	Gain 4.12%	Loss 5.7%

Exchange of gases in lungs can be divided into two steps -

Uptake of O_2 by blood in lung: The PO_2 (partial pressure of oxygen) of the alveolar air is higher than the PO_2 of blood in alveolar capillaries. Due to a PO_2 difference between air and blood, oxygen diffuses rapidly from the alveolar air into the blood of alveolar capillaries.

Release of CO_2 by the blood: The PCO_2 (partial pressure of carbon dioxide) of blood reaching the alveolar capillaries is higher than the PCO_2 of alveolar air. Therefore, carbon dioxide diffuses from the blood of alveolar capillaries into the alveolar air.

(ii) Exchange of gases in tissues: In the tissues, exchange of gases occurs between the blood and the tissue cells. This exchange occurs via tissue fluid that bathes the tissue cells. The blood reaching the tissue capillaries has PO_2 higher than that in the tissue cells and PCO_2 lower than that in the tissue cells. The tissue cells constantly use oxygen in oxidation that produces carbon dioxide. Therefore, they always have lower PO_2 and higher PCO_2 than the blood coming to them. Because of PO_2 and P_{CO_2} differences between blood and tissue cells, oxygen separates from oxyhaemoglobin and diffuses from the blood into the tissue fluid and hence into the tissue cells; and carbon dioxide diffuses from the tissue cells into the tissue fluid and thence into the blood in the tissue capillaries. Gases mostly diffuse through the tissue fluid as such, only small amounts dissolve in it.

Exchange of gases in the tissues that lowers the PO_2 of the blood and raises its PCO_2 is called internal respiration. The blood deoxygenated by this respiration returns to the right side of the heart that sends it to the lungs for reoxygenation.

- (3) **Transport of gases**: Blood carries O_2 from respiratory organs to the tissue cells for oxidation and CO_2 from tissue cells to respiratory organs for elimination. Blood should be slightly alkaline to help the transport of O_2 and CO_2 properly.
- (i) **Transport of oxygen:** Lung contains atmospheric air. From the lung O_2 diffuses into the blood. The blood transport O_2 from the lung to the cells. This is called oxygen transport. O_2 is carried in the blood in three forms –
- (b) As oxyhaemoglobin (HbO_2) : Most of O_2 is transported in the form of oxyhaemoglobin. 98.5% in the form of HbO_2 and 1.5% is carried in the dissolved state in watery blood plasma.

Oxygen-haemoglobin dissociation curve

When a graph is plotted between percent saturation of haemoglobin and oxygen tension, a curve is obtained termed as O_2 - Hb dissociation curve. Oxygen-Hb dissociation curve is sigmoid shaped-or S shaped. This sigmoid shaped curve is characteristic for Hb.

Body tissue obtain oxygen from oxyhaemoglobin because of its dissociation caused by low O_2 and high CO_2 concentration. Under a given oxygen concentration in blood, dissociation of oxyhaemoglobin will increase if pH of blood falls. When partial pressure of CO_2 rises (blood pH decreases), dissociation curve of oxyhaemoglobin at $37^{\circ}\mathrm{C}$ shift to right. Effect of high temperature and low pH (high PCO_2) are similar. P_{50} indicates the oxygen concentration at which 50% haemoglobin of blood is saturated with O_2 .

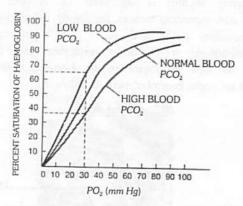

Fig: 5.2-13 Effect of PCO₂ on affinity of hemoglobin for oxygen

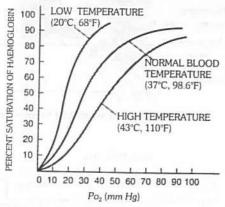

Fig: 5.2-14 Oxygen-hemoglobin dissociation curve showing the relationship between temperature and hemoglobin saturation with O_2

Bohr's effect: Hb- O_2 dissociation curve shifts to right when CO_2 tension in blood is high. Bohr discovered this effect in 1904. Bohr effect is the effect of CO_2 on oxyhaemoglobin. Deoxygenation of oxygaemoglobin is directly proportional to blood pCO_2 . Extent of Bohr's effect depends upon the tension of CO_2 in blood only. CO_2 of tissue fluid and alveoli does not exert Bohr's effect. During exercise muscles need more O_2 and want to remove CO_2 which has high production. Because of pressure gradient

 CO_2 moves from tissues fluid to capillary blood \rightarrow Exert Bohr's effect \rightarrow O_2 release is hastened from Hb- O_2 i.e. Hb- O_2 curve shifts to right.

Haemoglobin: Oxygen carrier or respiratory pigment in vertebrates blood is haemoglobin. Hb molecule is made of two components haem and globin. Globin part is globulin protein which is made of four polypeptide chain, two α chains (141 amino acid) and two β chains (146 amino acid). Thus total no. of amino acid in Hb 574. Haem is iron containing compound and belongs to the class of compound called protoporphyrins. Hb in RBC synthesized before loss of nucleus. Iron of Hb is in ferrous state (Fe^{++}) and even after the combination with O_2 it remains ferrous. One Hb molecule has 4 haem molecules. Each haem is associated without polypeptide chain. Each Hb molecule can combine with one molecule (2 atoms) of oxygen. Thus each molecule of Hb combines 4 molecules of O_2 .

Myoglobin : It is chemically and functionally similar to Hb. It is made up of one polypeptide chain (153 amino acids) attached with on haem group. P_{50} value for myoglobin is 5 mm Hg. This indicates that myoglobin release oxygen less readily than Hb. It is found in muscles. It acts as a store house for O_2 . An average man can store about 1.5 litre oxygen in myoglobin. Hb- O_2 dissociation curve for myoglobin is hyperbola.

- (ii) **Transport of** CO_2 : Transportation of CO_2 by blood is much easier due to its high (20 times that of O_2) solubility in water. Blood can carry upto 50% or 60% of CO_2 by volume, but normally about 4 ml of CO_2 on an average is transported from tissue to the lungs in each 100 ml of blood in man. With 5 litres of cardiac output per minute, the blood thus transports about 200 to 220 ml of CO_2 each minute. Obviously, this is the rate at which CO_2 is produced and released into tissue fluids by cells, and at which it diffuses out into alveolar air from pulmonary arterial blood. The blood transports this CO_2 in three ways.
- (a) In dissolved state: Deoxygenated (PCO_2 is 45 to 46 mm Hg) and oxygenated (PCO_2 is 40 mm Hg) bloods respectively carry about 2.7 and 2.4 ml of CO_2 per 100 ml of blood in dissolved state in plasma (= in solution with plasma). Thus, about 0.3 (2.7 minus 2.4) ml of CO_2 is transported by each 100 ml. of blood in dissolved state in plasma. This is about 7% of all the CO_2 transported by blood from tissues to the lungs.
- (b) In the form of bicarbonate ions: Most of the CO_2 that dissolved in blood plasma reacts with water, forming carbonic acid $CO_2 + H_2O = H_2CO_3$ (carbonic acid)

This reaction is very slow in plasma, but occurs very rapidly inside RBCs, because an enzyme, carbonic anhydrase, present in RBCs, accelerates its rate about 5000 times. That is why, about 70% of the CO_2 (about 2.5 ml per 100 ml of blood), received by blood from the tissues, immediately enters into RBCs and hydrated to carbonic acid. Almost as rapidly as formed, all carbonic acid of RBCs dissociates into hydrogen and bicarbonate ions (H^+ and HCO_3^-). The hydrogen ions mostly combine with heamoglobin for

keeping the pH of blood. (7.4) in steady state, because haemoglobin is a powerful acid base buffer. Being quite diffusible, the bicarbonate ions, on the other hand, diffuse from RBCs into the plasma. To maintain electrostatic neutrality of plasma, many chloride ions, in turn, diffuse from plasma into the RBCs. Obviously, the chloride contents of RBCs increase when oxygenated blood becomes deoxygenated. This is termed "chloride or Hamburger shift".

Sequence of events: From tissues CO_2 enters in plasma \rightarrow a small fraction of CO_2 is dissolved in plasma \rightarrow rest of CO_2 enters into the RBC \rightarrow within RBC CO_2 combines with H_2O in presence of enzyme carbonic anhydrase and forms $H_2CO_3 \rightarrow H_2CO_3$ splits into H^+ and $HCO_3^- \rightarrow$ most of the HCO_3^- comes out of RBC and enters in plasma and form $NaHCO_3$, small fraction stays back within the RBC to form $KHCO_3$ and H^+ combine with Hb to form reduced haemoglobin H.Hb.

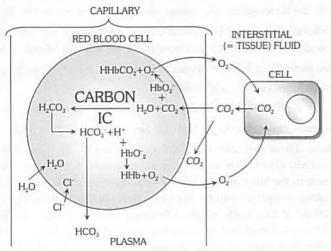

Fig: 5.2-15 Transportation of CO2 by blood

(c) In the form of carbamino compounds: In addition to reacting with water, CO_2 also directly and reversibly reacts with haemoglobin, loosely binding with it and forming an unstable compound, called carbaminohaemoglobin (CO_2HHb). It also similarly forms loose bonds with some plasma proteins. It is estimated that about 23% of the CO_2 (1 ml per 100 ml of blood), collected from cells through tissue fluids, is transported by blood in this form.

Table: 5.2-6 Transformation of CO₂ in various forms

Transformation forms of CO ₂	Transported quantity	
CO ₂	7 % (0.3 ml/100ml of blood)	
HHbCO ₂	23% (1ml/100 ml of blood)	
HCO ₃ -	70% (2.5 ml/100 ml of blood)	

Haldane effect and CO_2 diffusion into the alveoli: Whereas the Bohr effect promotes O_2 transport, the Haldane effect is important in promoting CO_2 transport. The Haldane effect results

from the simple fact that oxyhaemoglobin behaves as a strong acid. This in turn, displaces CO_2 from the blood in two ways.

- (1) Due to its increased acidity, the haemoglobin loses its capacity to combine with CO_2 . Hence all carbamino haemoglobin dissociates to release its CO_2 .
- (2) Secondly, the highly acidic oxyhaemoglobin releases an excess of H^+ which bind with bicarbonate ions (HCO $_3^-$), forming carbonic acid. The latter soon dissociates into H_2O and CO_2 . This CO_2 diffuses into the alveoli.

Thus, in the lung, the haldane effect, increases release of CO_2 because of O_2 uptake by haemoglobin. In the tissues a reverse process occurs. The Haldane effect increases CO_2 uptake because of removal of O_2 from haemoglobin.

Control of breathing

Respiratory rhythm is controlled by nervous system. Inspiratory and expiratory centres are jointly called rhythmicity centres. Inspiratory centre is dominant over expiratory centre. When pneumotaxic is stimulated respiration rate increases inspiration as well as expiration is shortened. Respiratory movements are under control of medulla oblongata.

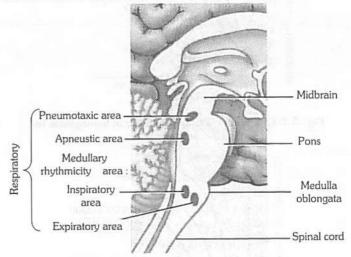

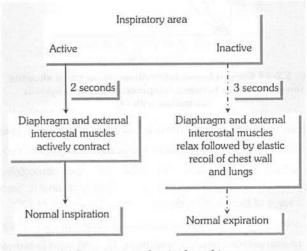

Fig: 5.2-16 Sagittal section of brain stem

(a) During normal quiet breathing

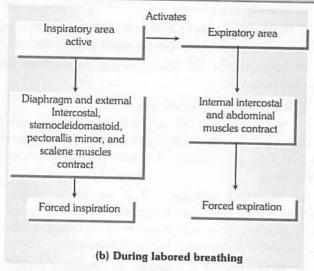

Table: 5.2-7 For the control of respiration following respiratory centres are found in hind brain

Type of centre	Location	Function		
Inspiratory centre	Medulla oblongata	Inspiration (2 second active condition).		
Expiratory centre	Medulla oblongata	Expiration (3 second inactive condition)		
Apneustic centre	Pons	Slow and deep inspiration		
Pneumotaxic centre	Pons	Control other centres and produce normal quite breathing		
Gasping centre	Pons	Sudden and shallow respiration		

- (1) **Chemical control**: This includes CO_2 , O_2 and H^+ conc. of blood. For detection of concentration of O_2 , CO_2 and H^+ ions in blood two types of receptors are found. These receptors are called chemoreceptor.
- (i) **Peripheral chemoreceptor:** These include two sets Carotid body is present in the wall of the left and the right common carotid arteries and aortic bodies is present in the arch of aorta. They are placed in the vascular endothelium and come in contact with the blood. When PO_2 decreases or increases in arterial blood, these receptors are stimulated and send impulses to respiratory centre to respectively increases or decreases the rate intensity of inspiratory signals.
- (ii) **Central chemoreceptors**: These are present on ventral surface of medulla. Cells of these centres are bathed in brain tissue fluid. They are in close vicinity of CSF. In brain tissue fluid as well as in CSF the CO_2 is converted into $H_2CO_3 \rightarrow H_2CO_3$ $H^+ + HCO_3^- \rightarrow H^+$ ions are liberated \rightarrow H^+ ions stimulate the central chemoreceptor (C.C) cell \rightarrow stimulation from C.C goes to respiratory centre \rightarrow Respiration stimulate.
 - (2) Effect of different gases
- (i) Effect of CO_2 : Rise in tension of arterial CO_2 or alveolar CO_2 causes stimulation of respiration. Both the rate and depth of respiration increased. This leads to washing out of CO_2 from body.

(ii) Effect of O_2 : Fall of O_2 concentration in inspired air causes stimulation of peripheral chemoreceptors. Neural impulse arises from peripheral chemoreceptors. These impulses go to respiratory centre and cause respiratory stimulation.

Respiration in frog

Frog is an amphibious animal i.e. they are live in water as well as on land hence according to their adaptations they posses different modes of respiration, which are as follows –

- (1) Cutaneous respiration: By the skin. Under water, during hibernation frog respires by only skin. On land cutaneous respiration continues as usual. Thus cutaneous respiration take place always. By cutaneous respiration frog fulfill its 30% need of oxygen.
- (2) Buccopharyngeal respiration: Like the skin, the mucosa of buccopharyngeal cavity in frog is also ideally adapted for gaseous exchange. Hence, while quietly floating upon water surface, and even when resting upon land, frogs respire by their buccopharyngeal cavity also. During this process, the mouth, gullet and glottis remain closed, but nares remain open.
- (3) **Pulmonary respiration:** In frog, pulmonary respiration accounts for about 65% of the total O_2 -intake. It particularly occurs when frogs lead an active life during rains and spring; either hopping upon land in search of food, or actively breeding in water.

Important concept of respiration

(1) Respiratory quotient (R.Q.): Respiratory quotient is the ratio of carbon dioxide output to oxygen usage during respiration. It is measured by Ganong's respirometer.

R.Q. =
$$\frac{\text{Volume of } CO_2 \text{ formed}}{\text{Volume of } O_2 \text{ utilized}}$$

Table: 5.2-8

High RQ	Low RQ
Due to fat deposition	When CO2 is fixed
Due to fever	When CO2 retain in tissue
Due to muscle exercise	In hibernating mammals
During glycolysis	Due to acidosis
In low O2 environment	Due to alkalosis
Due to oxidation of	Due to diabetes
pyruvic acid.	In starvation
	During gluconeogenesis
	During glyconeogenesis

The volume of RQ depends upon the type of fuel substance being utilized for energy production.

Table: 5.2-9 RQ of various subtrates

Respiratory substrate	Respiratory quotient	
Carbohydrate	1.00	
Proteins	0.5 - 0.9 Slightly less than 1 (0.9)	
Fats	0.7	
Organic acid	1.33	

In an organism utilizing carbohydrates as source of energy anaerobically, the RQ is likely to be infinity. When carbohydrates are substrates for respiration, it is called 'floating respiration'. Diabetic patient shows low R.Q. due to increased dissimilation of fats and the decreased dissimilation of carbohydrate.

- (2) Effect of CO: Carbon monoxide is a poisonous gas. Hb has maximum affinity for CO. Carbon monoxide binds with haemoglobin at the same place where O2 binds, but about 250 times more readily than O_2 . Hence, it readily displaces O_2 from haemoglobin and even a 0.4 mm Hg partial pressure of CO in alveolar air is enough to occupy about half of the haemoglobin of pulmonary blood rendering it useless for O2 transport. A CO pressure of about 0.7 mm Hg (concentration of about 1%) in alveolar air can be lethal. That is why, the atmosphere of industrial areas, being loaded with chimney smoke, is regarded harmful to health. It forms carboxyhaemoglobin with Hb which is most stable. Sudden deep inspiration is due to either increase in concentration of CO_2 or decrease in concentration of O_2 . Forced deep breathing for a few minutes by a person sitting at rest may be followed by a temporary cessation of breathing. This is influenced by too much O_2 and least CO_2 in blood.
- (3) **Regulation at high altitudes**: At high altitudes, the composition of air remains almost the same as at sea-level, but the density (barometric pressure) of air gradually decreases. While ascending up a mountain, one inspires thin air, getting less oxygen. Less O_2 level in the blood results in hypoxia. The chemoreceptor simulatory mechanism progressively increases the rate of ventilation. Ventilation ordinarily does not increase significantly until one has ascended to about 2500 metres, because the P_{CO_2} and pH remain almost normal.

Disorders of Respiratory system

- (i) **Hypoxia**: Hypoxia is a condition of oxygen shortage in the tissues. It is of two types:
- (a) **Artificial Hypoxia**: It results from shortage of oxygen in the air as at high (over 2400 m.) altitudes. It causes mountain sickness characterised by breathlessness, headache, dizziness, nausea, vomiting, mental fatigue and bluish tinge on the skin and mucous membranes.
- (b) **Anaemic Hypoxia**: It results from the reduced oxygencarrying capacity of the blood due to anaemia (decreased haemoglobin content in blood) or carbon monoxide poisoning (some haemoglobin occupied by CO). in both cases, less haemoglobin is available for carrying O_2 .
- (ii) **Asphyxia** (**Suffocation**): The O_2 content of blood falls and the CO_2 content rises and paralyses the respiratory centre. Breathing stops and death occurs.
- (iii) Bad cold: Disease-causing microbes present in the air attack respiratory tract, producing inflammation of the mucous membrane and caused increased secretion:
 - (a) Rhinitis in the nasal chambers.

- (b) Sinusitis in the sinuses.
- (c) Pharyngitis in the pharynx, often called sore throat, and is usually accompanied by tonsillitis (enlargement of tonsils).
- (d) Laryngitis in the larynx, causing hoarse voice and difficulty in speaking.
 - (e) Bronchitis in the bronchioles.
- (iv) Emphysema: The air-pollutants that cause chronic bronchitis, may breakdown the alveoli of the lungs, reducing the surface area for gas exchange. The victim becomes permanently short of breath.
- (v) Bronchial asthma: It is an allergic attack of breathlessness associated with bronchial obstruction or spasm of smooth muscle (contraction), characterized by coughing difficult breathing and wheezing patient has trouble exhaling.
- (vi) **Bronchitis**: It is caused by the permanent swelling in bronchi. As a result of bronchitis cough is caused and thick mucus with pus cells is spitted out. Dyspnea and fever develops. Dyspnea means hunger of air or deficiency of oxygen in the blood or development of hypercapnia i.e., increase of CO_2 concentration in blood. This disease is accelerated by fatigue, malnutrition, cold etc. the patient experiences difficulty in breathing. Here hypertrophy and hyperplasia of bronchi takes place.
- (vii) **Pneumonia**: Oxygen has difficulty diffusing through the inflammed alveoli and the blood PO_2 may be drastically reduced. Blood PCO_2 usually remain normal because CO_2 diffuses through the alveoli more easily than O_2 . In chronic patients of common cold and influenza, the lining epithelium of bronchi and lungs is inflammated. This disease is caused by streptococus pneumoniae, other bacteria, fungi, protozoans, viruses and the patient feels difficulty in breathing. Its prominent symptoms are trembling, pain in chest, fever, cough delirium etc. This disease is prevalent in either children or elderly persons in old age.
- (viii) Lung cancer: It is believed that by excess smoking, lung cancer (carcinoma of lungs) is caused. The tissue increases limitlessly, which is called malignancy. This disease is fatal. The frequency of occurrence of this disease in smokers is 20% more. Malignancy of tissues (neoplasia) causes pressure on the cells of other tissues and destroys them. The blood capillaries are ruptured, blood starts flowing and death is caused by excessive bleeding.
- (ix) **Tuberculosis:** This disease is also called T.B. and was considered fatal, but these days its full cure is possible. Thus, disease is called curable, these days. It is caused by bacteria Mycobacterium tuberculosis. These bacteria settle in lungs at different places and convert normal tissue into fibrous tissue. Since the respiratory surface is decreased, the difficulty in breathing is also experienced. If the patients start taking medical advice and the medicines right from the initial stage regularly, the patients can be fully cured of the disease. Now a days a new therapy DOT (Direct observed treatment) is used for tuberculosis treatment, recently launched by Indian Government. Many other drugs like rifampin and isoniazid are successful for the treatment of tuberculosis. Tuberculosis bacteria are spread by inhalation and exhalation.

UNIVERSAL BOOK DEPOT 1960

(x) Coryza: Common cold, due to rhinoviruses in adult.

(xi) Influenza: Flu.

- (5) Occupational lung disease: It is caused because of the exposure of potentially harmful substances. Such as gas, fumes or dusts, present in the environment where a person works. Silicosis and asbestosis are the common examples, which occur due to chronic exposure of silica and asbestos dust in the mining industry. It is characterised by fibrosis (proliferation of fibrous connective tissue) of upper part of lung, causing inflammation.
- (i) **Prevention and cure**: Almost all the occupational lung diseases, express symptoms after chronic exposure, *i.e.*, 10-15 years or even more. Not only this, diseases like silicosis and asbestosis are incurable. Hence, the person likely to be exposed to such irritants should adopt all possible preventive measures. These measures include:
 - (a) Minimizing the exposure of harmful dust at the work place.
- (b) Workers should be well informed about the harm of the exposure to such dusts.
- (c) Use of protective gears and clothing by the workers at the work place.
 - (d) Regular health check up.
- (e) Holiday from duty at short intervals for the workers in such areas.
- (f) The patient may be provided with symptomatic treatment, like bronchodilators and antibiotics, to remove underlying secondary infection.

(6) Special respiratory movements

Cough

- (1) It is reflex action stimulation takes place from trachea and lungs.
 - (2) Centre is medulla oblongata.
- (3) Cough is a forcible expiration usually produced after a prolonged inspiration.
- (4) When some food particle enters the windpipe instead of oesophagus, it is expelled by a process of coughing.
 - (5) Air exploded through the mouth.

Sneezing

- (1) Reflex action stimulated by olfactory epithelium of nasal chamber.
- (2) Sneezing is a forcible expiration, air explodes out through nose and mouth.

Hiccuping

- Hiccuping is a noisy inspiration caused by muscular spasm of diaphragm at irregular intervals.
 - (2) Noise is due to sudden sucking of air through vocal cords.
- (3) Stimulation of hiccuping is usually irritation of the sensory nerve endings of the digestive tract.

Yawning: Yawning is a prolonged inspiration. Low oxygen tension in the blood causes yawning.

Table: 5.2-10 Terminology

Apnea	Absence of breathing
Eupnea	Normal breathing
Hypopnea	Decreased breathing rate
Нурегрпеа	Increased breathing rate
Dyspnea	Painful breathing
Orthopnea	Inability to breathe in a horizontal position
Acapnoea	Absence of CO ₂ in blood
Нуросарпеа	Deficiency of CO ₂ in blood
Hypercapnea	Excess of CO ₂ in blood
Hypoxaemia	Lack of O ₂ in arterial blood
Anoxia	Absence of O ₂ in tissues
Нурохіа	Lack of O ₂ in tissues
Tachypnea	Rapid breathing

Table: 5.2-11 Respiratory pigments

Name of pigment	Colour (oxidised)	Metal	Place	Example
Haemoglobin	Red	Fe	RBC	Chordata (Vertebrate)
Haemocyanin	Blue	Cu	Plasma	Mollusca and arthropoda
Chlorocruorin	Green	Fe	Plasma	Annelida, sabella, serpulids
Haemoerythrin	Red	Fe	Corpuscle	Annelida, Sipunculoid ea, lingula
Vanadium	Green	Va	Vanadocytes in Plasma	Urochordat a
Echinochrome	Red	Fe	Coelomic fluid	Echinoderm ata
Pinnoglobin	Brown	Mn	Coelomic fluid	Pinna
Moledin	Brown	Мо	Coelomic fluid	Holothuria
Heamoglobin	Red	Fe	Plasma	Earthworm, nereis, arenicola, chironomas insect, planorbis.
Erythrocruonin	Red	Fe		Leech

Tips & Tricks

- ✓ Protoplasmic respiration refers to the respiration of proteins.
- Polarography is employed to measure the concentration of oxygen in fluid.
- Accumulation of blood in pleural cavity is called haemothorax.
- Accumulation of water is called hydrothorax.
- Accumulation of pus is called pyothorax.
- Besides lungs, the term alveolus is associated with bony socket for tooth, and in mammary glands also.
- ✓ In general, a man respires about 16 18 time in a minute.
- A five year old child respires 26/min.
- A fifty year old man respires 18/min.
- No respiratory pigment in cockroach.
- Smaller the animal higher the respiratory rate.
- Rate of respiration is directly proportional to concentration of CO₂ in blood.
- Metabolic rate of body is directly proportional to the total pulmonary ventilation.
- Intra aortic balloon pump is inflated by helium.
- ✓ In pregnant woman diaphragm does not take part in breathing.
- ✓ In frog larynx and trachea are fused together to form laryngo tracheal chamber.
- ∠ Lungs of frog acts as positive pressure pump, while lungs of mammal acts as negative pressure pump.
- Disorder such as asthma and emphysema can greatly reduce the expiratory reserve volume.
- At about 4 weeks foetal development, the respiratory system begins as an outgrowth of endoderm of foregut, known as laryngotracheal bud.
- After 6 months, formation of alveoli of lungs.
- The pneumotoxic and the apneustic area in pons.
- ✓ If arterial PCO₂is more than 40 mm Hg, the condition is called as hypercapnia.
- ✓ If arterial PCO₂ is lower than 40 mm Hg, the condition is called as hypocapnia.

- ✓ Double Bohr effect refers to the situation in the placenta where the Bohr effect is operative in both the maternal and foetal circulation.
- \angle Ozone, a strong oxidizing agent, oxidises iron of Hb and forms a stable compound methaemoglobin which can not release O_2 .
- Air bladder perform the functions of hydrostatic organ, sound production, audition and respiration.
- Foetal Hb takes O₂ from mother haemoglobin across the
 placenta due to double Bohr effect.
- ✓ In embryos of mammals, respiration takes place by chorion.
- In lungs of birds capillaries are present in place of alveoli.
- \angle Exchange of O_2 takes place twice in lungs of birds. It is called double respiration.
- Aquatic salamander is lungless amphibians.
- In snakes, only right lung in functional, left lung is reduced.
- In penguins double trachea is present.
- In pregnant females most part during breathing is played by intercostal muscles.
- Whales and other aquatic mammals suffocate on land because their intercostal muscles can not expand their chest due to their massive body weight.
- ✓ In monkeys, kangaroo and other jumping animals, intercostal muscles play important role in breathing.
- ✓ Smoke inhalation injury Has three components that occur in sequence

Inhibition of O2 delivery and utilization.

Upper airway injury from heat.

Lung damage from acid and aldehyde in smoke.

SARS - Severe Acute Respiratory Syndrome -

SARS is a highly infectious disease caused by corona virus.

Corona virus is a RNA virus, its genome was sequenced within 15 days.

The origin of SARS is from South China, this disease spread to Hongkong.

Bird sellers and persons in contact with birds suffer from SARS.

Symptoms of infections are flue like. Fever occurs with dry cough. There is difficulty in breathing. Fluid fills in lungs and death occurs within one week of infection from respiratory failure.

Rate of death was initially 4% but now death rate has increased to 10%.

Line of treatment is quarnatine and ribovinin durgs.

The causative agent of SARS was identified by Dr. Malik Peiris of Microbiology Department of Hongkong University.

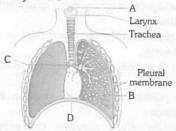

Ordinary Thinking

Objective Questions

Respiratory organs

- Which one of the following has the smallest diameter [NCERT; Kerala CET 2003]
 - (a) Right primary bronchus
 - (b) Left primary bronchus
 - (c) Trachea
- (d) Respiratory bronchiole
- 2. Oxygen in lungs ultimately reaches in
- [MP PMT 1998]

- (a) Alveoli
- (b) Trachea
- (c) Bronchus
- (d) Bronchioles
- 3. Respiratory pigment in cockroach is
 - [RPMT 1999; Odisha JEE 2010]
 - (a) Haemozoin
- (b) Haemocyanin
- (c) Haemoglobin
- (d) Absent
- 4. See the following diagrammatic view of human respiratory system. Identify A to D [NCERT]

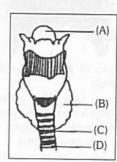

- (a) A Soundbox, B Alveoli, C Bronchioles, D Diaphragm
- (b) A Soundbox, B Alveoli, C Bronchus, D Diaphragm
- (c) A Epiglottis, B Alveoli, C Bronchioles, D Diaphragm
- (d) A Epiglottis, B Alveoli, C Bronchus, D Diaphragm
 In man and mammals, air passes from outside into the lungs through [NCERT; BHU 1999; CPMT 2000]
 - (a) Nasal cavity, larynx, pharynx, trachea bronchi, alveoli
 - (b) Nasal cavity, larynx, pharynx, trachea, bronchioles, alveoli
 - (c) Nasal cavity, pharynx, larynx, trachea, bronchioles, bronchi, alveoli
 - (d) Nasal cavity, pharynx, larynx, trachea, bronchi, bronchioles, alveoli
- 6. Which of the following is a respiratory organ of scorpion
 - [CBSE PMT 2002; BVP 2002]
 - (a) Gill
- (b) Lung
- (c) Ctenidia
- (d) Book lung
- During forced expiration, actively contracting muscles include the [CBSE PMT 2001]
 - (a) Diaphragm
 - (b) External intercostals
 - (c) Abdominal muscles
 - (d) Diaphragm and intestinal muscle
- 8. In which part gaseous exchange take place in rabbit
 - [NCERT; RPMT 2001]
 - (a) Trachea and alveolar duct
 - (b) Trachea and bronchi
 - (c) Alveolar duct and alveoli
 - (d) Alveoli and tissues

- Difference between trachea and fallopian tube is[CPMT 1995]
 - Trachea is related with respiration where as fallopian tube is related with reproduction
 - (b) Trachea is related with respiration and fallopian tube with excretion
 - (c) Trachea is related with reproduction and fallopian tube with excretion
 - (d) Trachea is related with reproduction and fallopian tube with respiration
- 10. Vocal cords are situated at
- [MP PMT 1995, 99]
- (a) Pharynx
- (b) Larynx
- (c) Glottis
- (d) Bronchial tube
- Carbon dioxide is transported via blood to lungs mostly
 [CBSE PMT 1995; Odisha JEE 2008]

[CBSE PM1 1995; Odisha JEE

- (a) As carbaminohaemoglobin and as carbonic acid
- (b) In the form of carbonic acid only
- (c) In combination with haemoglobin only
- (d) Dissolved in blood plasma
- Which is a common passage in swallowing food and breathing [CPMT 1993; MP PMT 1995]
 - (a) Larynx
- (b) Gullet
- (c) Glottis
- (d) Pharynx
- The diagram represents the human larynx. Choose the correct combination of labelling from the options given

[Kerala PMT 2008]

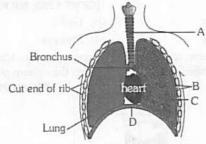

- (a) A Larynx, B Parathyroid, C Tracheal cartilage, D Trachea
- (b) A Naso Larynx, B Thyroid, C Tracheal cartilage, D – Trachea
- (c) A Trachea, B Thyroid, C Bronchiole, D Tracheal cartilage
- (d) A Epiglottis, B Thyroid, C Tracheal cartilage, D Trachea
- (e) A Epiglottis, B Parathyroid, C Trachea, D Tracheal cartilage
- 14. In human beings, lungs are divided into
 - (a) 3 right and 2 left lobes
- (b) 2 right and 3 left lobes
- (c) 2 right and 2 left lobes
- (d) None of these
- Similarity between the trachea of cockroach and rabbit is that [AFMC 1994; CPMT 1995]
 - (a) Both are paired and branched
 - (b) Ciliated epithelium is present in both
 - (c) Walls of both can not be deformed
 - (d) In both head originates from pharynx
- 6. In rabbit alveolar ducts originate from
 (a) Bronchi (b) Tra
 - (b) Trachea
 - (c) Bronchiole
- (d) Respiratory bronchiole

- The cartilage present in the larynx of rabbit are [BHU 2002]
 - (a) Thyroid, cricoid, arytenoid
 - (b) Thyroid, cricoid, epiglottis
 - (c) Thyroid, cricoid, ethmoid
 - (d) Thuroid, cricoid, palatine
- 18. In which of the following animals Hb (Haemoglobin) is found [CPMT 1998; DPMT 2007] dissolved in plasma

In which of the following animals, respiration occurs with [CPMT 2003] out any respiratory organ

- (a) Planaria
- (b) Cockroach
- (c) Sepia
- (d) Earthworm
- The exchange of gases $(O_2$ and $CO_2)$ in a mammal takes 19. [NCERT; CPMT 1992] place in
 - (a) Trachea
- (b) Bronchi
- (c) Bronchiole
- (d) Alveoli
- The figure shows a diagrammatic view of human respiratory 20. system with labels A, B, C and D. Select the option which gives correct identification and main function and/or characteristic

[NEET 2013]

- (a) D Lower end of lungs diaphragm pulls it down during inspiration
- (b) A Trachea long tube supported by complete cartilaginous rings for conducting inspired air
- (c) B Pleural membrane surround ribs on both sides to provide cushion against rubbing
- (d) C Alveoli thin walled vascular bag like structures for exchange of gases
- Larynx is found in 21.

- [MP PMT 1992]
- (a) Both frog and rabbit
- (b) Neither frog nor rabbit
- (c) Frog but not in rabbit
- (d) Rabbit but not in frog
- The long trachea of rabbit contains 22.

- [CPMT 1992]

- (a) Buccal cord
 - (b) Thyroid
 - (c) Complete tracheal cartilage
 - (d) Incomplete tracheal cartilage
- The right lung of rabbit has four lobes. They are 23.

[CPMT 1992; MP PMT 1995]

- (a) Anterior lobe, anterior azygous, posterior lobe and right anterior
- (b) Posterior lobe, posterior and anterior azygous, right anterior and right posterior
- (c) Anterior azygous, right anterior, right posterior and posterior azygous lobe
- (d) Anterior lobe, anterior azygous, right anterior and posterior azygous lobe
- There is a membrane covering the lungs, called 24.

[MP PMT 1994; KCET 1999; MH CET 2000; Pb. PMT 2004; AFMC 2005]

- (a) Peritonium
- (b) Pleura
- (c) Pericardium
- (d) Duramater

In rabbit the lungs are lodged in

[CPMT 1992]

- (a) Thoracic cavity
- (b) Abdominal cavity
- (d) Pericardial cavity (c) Pleural cavity
- The most important function of diaphragm of the mammals 26.
 - (a) To divide the body cavity into compartment
 - (b) To protect lungs
 - (c) To aid in respiration
 - (d) To aid in ventilation
- The pigment haemocyanin is found in IBVP 2000: AIIMS 2000; CBSE PMT 2002; MHCET 2002]
 - (a) Chordata
- (b) Annelida
- (c) Mollusca
- (d) Echinodermata
- Lung ventilation movements are due to [Odisha JEE 2005] 28.
 - (a) Costal muscles and diaphragm
 - (b) Costal muscles
 - (c) Diaphragm
 - (d) Wall of the lungs
- [AIEEE Pharmacy 2006] What is true about haemoglobin 29.
 - (a) It is a dipeptide and present in red blood corpuscles in blood warm
 - (b) It is present in the dissolved state in blood plasma in earthworm
 - (c) It is a dipeptiede in mammals and localised in red blood corpuscles
 - (d) It is present in dissolved state in blood plasma in scorpions
- The structure which prevents the entry of food into 30. respiratory tract is
 - (a) Pharynx
- (b) Larynx
- (c) Glottis
- (d) Epiglottis
- In which animal, diaphragm has no role in respiration
 - [MH CET 2003]
 - (a) Frog
- (b) Rat
- (c) Camel
- (d) Rabbit
- Thyroid is a cartilagenous plate in [CPMT 1992, 93]
 - (a) Skull of rabbit
- (b) Larynx of rabbit
- (c) Vertebrae of rabbit
- (d) Sternum of rabbit
- 33. The diaphragm in rabbit is a
- [J & K CET 2005]
- (a) Gap between the incisor and premolar teeth
 - (b) Membrane which surrounds and protects the brain
 - Membrane which lies between the external auditory meatus and tympanic cavity of the ear
 - (d) Partition of muscular septum separating the thoracic cavity from abdominal cavity

Pulmonary volumes and capacities

- 1. What is vital capacity of our lungs
- [CBSE PMT 2008]
- (a) Inspiratory reserve volume plus expiratory reserve volume
- (b) Total lung capacity minus residual volume
- (c) Inspiratory reserve volume plus tidal volume
- (d) Total lung capacity minus expiratory reserve volume
- The vital capacity of the lung signifies the volume of air
 - (a) Breathed in during normal inspiration
 - (b) Breathed out with forcible expiration
 - (c) Breathed in with forcible inspiration
 - (d) With deep inspiration and forcible expiration

- Arrange the following in the order of increasing volume
 - (1) Tidal volume
 - (2) Residual volume
 - (3) Expiratory reserve volume
 - (4) Vital capacity
- [NCERT; AIIMS 2007]
- (a) 1 < 2 < 3 < 4
- (b) 1 < 3 < 2 < 4
- (c) 1 < 4 < 3 < 2
- (d) 1 < 4 < 2 < 3
- The volume of air present in the lungs after forceful expiration is called as [KCET 2006]
 - (a) Tidal volume
- (b) Residual air
- (c) Complementary air
- (d) None
- The largest quantity of air that can be expired after a 5. maximum inspiratory effort is [NCERT; CPMT 1999; Pb. PMT 1999; CPMT 2004; MP PMT 2007:
 - Odisha JEE 2011]
 - (a) Residual volume
- (b) Tidal volume
- (c) Vital capacity of lung
- (d) Lung volume
- The volume of air which remains in the conducting airways and is not available for gas exchange is called
 - [J & K CET 2012]

- (a) Vital capacity
- (b) Functional residual capacity
- (c) Forced expiratory volume
- (d) Anatomic dead space
- 7. How much amount of volume of air is in lungs FRC

[GUJCET 2015]

- (a) 1500 ml to 1600 ml
- (b) 2100 ml to 2500 ml
- (c) 2500 ml to 3000 ml
- (d) 1600 ml to 2100 ml
- 8. The enzyme essential for the transport of CO2 as bicarbonate in blood is [MP PMT 2012; Kerala PMT 2012]
 - (a) Carboxypeptidase
- (b) Succinic dehydrogenase
- (c) Carbonic anhydrase
- (d) Thrombokinase
- (e) Lactase
- The amount of volume of air that can be inspired/expired 9. normally is called [DPMT 2007; AFMC 2009, 10; J & K CET 2010; GUJCET 2014]
 - (a) Tidal volume
- (b) Vital capacity
- (c) Residual volume
- (d) Normal volume
- The area of inner surface of bronchiole is

[KCET 2001; MH CET 2003]

- (a) $1 m^2$
- (b) 10 m²
- (c) 100 m²
- (d) 1000 m²
- Capacity of human lung for air 11. [Odisha JEE 2005]
 - (a) 3000 ml
- (b) 1500 ml
- (c) 1000 ml
- (d) 500 ml
- 12. Residual volume is

- [KCET 2007]
- (a) Lesser than tidal volume
 - (b) Greater than inspiratory volume
 - (c) Greater than vital capacity
 - (d) Greater than tidal volume
- 13. Vital capacity of the lung includes

[Kerala PMT 2007; DPMT 2007; BHU 2012] Or

After forceful inspiration, the amount of air that can be breathed out by maximum forced expiration is equal to

(a) IRV + TV + ERV

- [WB JEE 2012]
- (c) ERV + TV
- (b) ERV + RV(d) IRV + TV
- (e) RV + ERV + TV + IRV

Match the items in Column - I with Column - II and choose the correct option

	Column - I	187	Column – II
A.	Tidal volume	1.	2500 to 3000 ml of air
B.	Inspiratory reserve volume	2.	1000 ml of air
C.	Expiratory reserve volume	3.	500 ml of air
D.	Residual volume	4.	3400 to 4800 ml of air
E.	Vital capacity	5.	1200 ml of air

[NCERT; CBSE PMT 1996; Pb PMT 2004; Kerala PMT 2007; AFMC 20121

- (a) A-3,B-4,C-2,D-1,E-5
- (b) A-3,B-1,C-2,D-5,E-4
- (c) A-3,B-1,C-4,D-5,E-4
- (d) A-5,B-4,C-2,D-1,E-2
- (e) A-4,B-3,C-2,D-1,E-5
- The partial pressure of oxygen in the alveolar air is

[Kerala PMT 2010]

- (a) 45 mm Hg
- (b) 95 mm Hg
- (c) 104 mm Hg (d) 110 mm Hg
- (e) 125 mm Hg
- The volume of 'anatomical dead space' air is normally [WB JEE 2012]
 - (a) 230 ml
- (b) 210ml
- (c) 190ml
- (d) 150 ml
- 17. The volume and surface area of a deer is 1,50,000 cm³ and $19,000 \, cm^2$ and of a squirrel is $625 \, cm^3$ and $530 \, cm^2$. The area available for heat loss per cm3 volume of the squirrel will be approximately [AMU (Med.) 2010]
 - (a) Seven times more than the deer
 - (b) Five times less than the deer
 - (c) Three times more than the deer
 - (d) Eleven times more than the deer
- 18. The urge to inhale in humans results from [DUMET 2010]
 - (a) Rising PCO₂
- (b) Rising PO2
- (c) Falling PCO₂
- (d) Falling PO2
- Listed below are four respiratory capacities (A-D) and four jumbled respiratory volumes of a normal human adult Respiratory capacities - Respiratory volumes
 - (A) Residual volume
- 2500 mL

1200 mL

- (B) Vital capacity
- 3500 mL
- (C) Inspiratory reserve volume (D) Inspiratory capacity
- 4500 mL
- Which one of the following is the correct matching of two capacities and volumes
 - [CBSE PMT (Pre.) 2010]
- (a) (A) 4500 mL, (B) 3500 mL
- (b) (B) 2500 mL, (C) 4500 mL
- (c) (C) 1200 mL, (D) 2500 mL
- (d) (D) 3500 mL, (A) 1200 mL

(c) A very efficient system of ventilating the alveoli with no

(d) An efficient system of ventilation of alveoli with little or

residual air

no residual air

8008.0	CPG1 1969		
20.	Complete and balanced the following reaction $Na_2HPO_4 + X \rightarrow Y + NaH_2PO_4$ [GUJCET 2015]	8.	Choose the right sequential phenomena among the following during the delivery of \mathcal{O}_2 from blood to tissue
	(a) $X = NaHCo_3$, $Y = NaCl$		P. Absorption of CO ₂ by the blood
	(b) $X = H_2CO_3$, $Y = NaH_2CO_3$		Q. Reaction of absorbed CO_2 with H_2O to from H_2CO_3
	(c) $X = NaHCO_3$, $Y = H_2CO_3$		within RBC and its conversion into H^+ and
	(d) $X = H_2CO_3$, $Y = N_3PCO_3$		HCO_3 ions
01			R. Reaction of absorbed CO_2 with H_2O in plasma to form
21.	Lungs are made up of air-filled sacs, the alveoli. They do not collapse even after forceful expiration because of		
	[NEET 2017]		H_2CO_3 and its conversion into H^+ and HCO_3^- ions
	(a) Residual Volume (b) Inspiratory Reserve Volume		S. Combination of H^+ with haem portion of HbO_2 to
	(c) Tidal Volume (d) Expiratory Reserve Volume		release O_2
	Process of respiration		T. Combination of HCO3 with haem portion HbO2 to
			form reduced haemoglobin and release of O_2
1.	Oxy-haemoglobin dissociates into oxygen and deoxy- haemoglobin at[DPMT 1992; MP PMT 1995; JIPMER 2002]		[WB JEE 2012]
	(a) Low O_2 pressure in tissue		(a) P, Q, T (b) P, R, S (c) P, Q, S (d) P, R, T
	(b) High O_2 pressure in tissue	9.	The alveoli of lungs are lined by [Kerala PMT 2008]
	(c) Equal O_2 pressure inside and outside tissue		(a) Simple epithelium (b) Squamous epithelium
	(d) All times irrespective of O_2 pressure		(c) Cuboidal epithelium (d) Columnar epithelium
2.	In lungs, the air is separated from the venous blood through	10.	(e) Ciliated epitheliumWhich of the following is used for long term energy storage
2.	[CBSE PMT 1997]	10.	by animals [Odisha JEE 2009]
	(a) Squamous epithelium + endothelium of blood vessel		(a) Amino acids (b) Glucose
	(b) Squamous epithelium + tunica media blood vessel		(c) Fat (d) Glycogen
	(c) Transitional epithelium + tunica external blood vessel	11.	Intra aortic balloon pump is inflated by (a) Hydrogen (b) Oxygen [JIPMER 2002]
	(d) None of these		(c) Helium (d) Chlorine
3.	The exchange of gases in the alveoli of the lungs takes place	12.	
	by [CBSE PMT 1998; AFMC 2002; Bihar BCECE 2005; Odisha JEE 2010]		[CPMT 1998; MP PMT 1999; AFMC 2003; Odisha JEE 2009]
	(a) Osmosis (b) Simple diffusion		Or
	(c) Passive transport (d) Active transport		In the muscles carbohydrates are stored in the form of
4.	Which of the following enzymes is absent in mitochondria		[WB JEE 2016]
	[CPMT 1998]		(a) Carbohydrates (b) Glycogen
	(a) Aconitase (b) Maleic dehydrogenase (c) Hexokinase (d) None of these	13.	(c) Fat (d) Protein The major fraction of CO_2 released during cellular
5.	If concentration of CO_2 is more the curve of oxygen will	13.	respiration is transported by the blood to the lung capillaries
	shift towards [MP PMT 2002]		[NCERT; CPMT 1998; MP PMT 1998, 2002;
	Or		AIEEE Pharmacy 2003; Odisha JEE 2010]
	Increase in body temperature makes oxygen haemoglobin		Or
	dissociation curve shift to [BHU 2012] (a) Right (b) Left		Approximately seventy percent of carbon-dioxide absorbed by the blood will be transported to the lungs
	(a) Right (b) Left (c) Central (d) None of these		[CBSE PMT 2014]
6.	The respiratory substrate yielding maximum number of ATP		(a) In combination with haemoglobin
	molecules among the following is [CBSE PMT 1994]		(b) As free CO_2
	(a) Glycogen (b) Amylase		(c) As carbonic acid or H_2CO_3
	(c) Ketogenic amino acid (d) Glucose		(d) In the form of bicarbonate ions
7.	Division of mammalian lungs into a very large number of	14.	#
	tiny alveoli around alveolar ducts opening into bronchioles, is [CBSE PMT 1995]		plasma is approximately [NCERT; Kerala PMT 2012]
	(a) An inefficient system of ventilation of alveoli though		(a) 97% (b) 20-25% (c) 7% (d) 49%
	with very little residual air		(c) 7% (d) 49% (e) 3%
	(b) An inefficient system of ventilating the alveoli resulting	15.	
	in very high percentage of residual air in the lungs	10.	() Dilacata bases demand

(a) Relaxes to become dome-shaped

(b) Contracts and flattens

(c) Expands

(d) Shows no change

- In hurdle race, which of the following is accumulated in the leg muscle [DUMET 2009]
 - (a) Performed ATP

(b) Glycolysis

(c) Lactate

- (d) Oxidative metabolism
- 17. Which of the following sets is most correct for the catabolism of an 18 carbon fatty acid [AMU (Med.) 2009]
 - (a) Mitochondria, beta-oxidation, 140 ATP molecules
 - (b) Cytosol, beta oxidation, 146 ATP molecules
 - (c) Mitochondria, beta oxidation, 146 ATP molecules
 - (d) Cytosol, beta oxidation, 140 ATP molecules
- 18. In humans, which among these is not a step in respiration [NCERT; Kerala PMT 2012]
 - (a) Pulmonary ventilation
 - (b) Alveolar diffusion of O₂ and CO₂
 - (c) Transport of gases by blood
 - (d) Diffusion of O₂ and CO₂ between blood and tissues
 - (e) Utilization of CO2 by cells for catabolic reactions
- 19. Hb is a

[MP PMT 2007]

- (a) Reproductive pigment (b) Respiratory pigment
- (c) Carbohydrate
- (d) Fat
- 20. According to Boyle's law, the product of pressure and volume is a constant. Hence, [KCET 2010]
 - (a) If volume of lungs is increased, the pressure decreases, proportionately
 - If volume of lungs is increased, the pressure also increases proportionately
 - (c) If volume of lungs is increased, the pressure decreases disproportionately
 - (d) If volume of lungs is increased, the pressure remains the
- Chloride shift occurs in respond to

[DPMT 2007]

- (a) H+
- (b) K
- (c) HCO₃
- (d) Na+
- 22. Which one of the following is a possibility for most of us in regards to breathing, by making a conscious effort

[NCERT; CBSE PMT (Mains) 2011]

- (a) One can consciously breathe in and breathe out by moving the diaphragm alone, without moving the ribs at all
- (b) The lungs can be made fully empty by forcefully breathing out all air from them
- One can breathe out air totally without oxygen
- (d) One can breathe out air through eustachian tubes by closing both the nose and the mouth
- Identify the correct statement with reference to transport of 23. respiratory gases by blood [KCET 2006]
 - (a) Haemoglobin is necessary for transport of carbon dioxide and carbonic anhydrase for transport of oxygen
 - (b) Haemoglobin is necessary for transport of oxygen and carbonic anhydrase for transport of carbon dioxide
 - (c) Only oxygen is transported by blood
 - (d) Only carbon dioxide is transported by blood
- 24. Which of the following statement correctly defines "Bohr
 - (a) Rise in PCO2 with a decrease in CO2 concentration
 - (b) Rise in PCO2 with an increase in CO2 concentration
 - (c) Rise in PCO_2 with an increase in CO_2 and decrease in PO_2
 - (d) Rise in PCO2 with a decrease in pH (concentration at which 50% haemoglobin of blood is saturated with oxygen)

- Under a given concentration in blood, dissociation of oxyhaemoglobin will increase if
 - (a) pH of blood falls
 - (b) pH of blood rises
 - (c) CO₂ concentration in blood falls
 - (d) Free fatty acid concentration in blood falls
- 26. Oxygen binding to haemoglobin in blood is [AIIMS 2012]
 - (a) Directly proportional to the concentration of CO2 in
 - (b) Inversely proportional to the concentration of CO2 in the medium
 - (c) Directly proportional to the concentration of CO in the
 - (d) Independent of the concentration of CO in the
- Bulk of carbon dioxide (CO2) released from body tissues into the blood is present as

[NCERT; CBSE PMT (Mains) 2011]

- (a) 70% carbamino-haemoglobin and 30% as bicarbonate
- (b) Carbamino-haemoglobin in RBCs
- (c) Bicarbonate in blood plasma and RBCs
- (d) Free CO2 in blood plasma
- O2 dissociation curve is 28. [NCERT; BHU 1995, 2000; CPMT 2000; DPMT 2007]
 - (a) Sigmoid
- (b) Slope
- (c) Straight line
- (d) Parabola
- In expiration condition, diaphragm becomes [CPMT 1993]
 - (a) Circular
- (b) Relaxed
- (c) Fully contracted
- (d) Expanded
- 30. Maximum amount of oxygen is lost from the blood in the [KCET 2006]
 - (a) Capillaries surrounding the tissue cells
 - (b) Arteries of the body
 - (c) Capillaries surrounding the alveoli
 - (d) Left auricle of the heart
- Which of the following activity does not take place during pulmonary respiration [Bihar MDAT 1995]
 - (a) Movement of buccal cavity
 - (b) Contraction and relaxation of sternohyal and pterohyal
 - Successive opening and closing of mouth and external nostrils
 - (d) All the above
 - (e) No activity takes place
- In anaerobic respiration the pyruvic acid in muscle will form [CPMT 1995, 99; AFMC 2002, 08; DPMT 2003]

(a) Lactic acid $(C_3H_6O_3)$ and H_2O

- (b) Alcohol (C2H5OH) and H2O
- (c) Acetaldehyde and H2O
- (d) Acetyl CoA and H2O
- Blood contains CO2 in which of the following forms
 - (a) NaHCO₃
- (b) Carbonic acid
- (c) Hb-CO₂
- (d) Hb-CO2 and CO

- Oxygen is transported to every cell of the body through [MP PMT 1994]
 - (a) RBC
- (b) WBC
- (c) RBC and WBC
- (d) RBC and hormones
- [CPMT 2005] Acquiring an oxygen debt is evidence that
 - (a) O2 cannot be stored in tissue
 - (b) Aerobic respiration is more complex than glycolysis
 - (c) Lactic acid can be converted into glycogen
 - (d) Anaerobic process are slower than aerobic processes
- The dissociation curve is associated with 36.
 - [NCERT] (b) Oxyhaemoglobin
 - (a) Oxygen (c) Carbon dioxide
- (d) Carbonic anhydrase
- Respiratory system is derived from 37.
- [CPMT 1993]

- (a) Ectoderm
- (b) Mesoderm
- (d) None of these
- (c) Endoderm
- The breakdown product of haemoglobin is called as 38.
 - [CBSE PMT 1993]

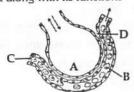

- (b) Bilirubin
- (c) Haemocynin
- (d) Skatol
- During respiration CO2 is transported in the form of 39.

[NCERT; CBSE PMT 1995, 2006; AFMC 2006, 10; BHU 2006]

- (a) Dissolved plasma
- (b) Sodium carbonate
- (c) KHCO3
- (d) Partly dissolved in plasma and partly in the form of sodium and potassium bicarbonate
- CO2 is dissolved in haemoglobin or blood plasma as 40.

[CBSE PMT 1993; WB JEE 2016]

- (a) Carbonates
- (b) Bicarbonates
- (c) Oxyhaemoglobin
- (d) Carboxyhaemoglobin
- The factor which does not affect the rate of alveolar 41. [NCERT: Kerala PMT 2011] diffusion is
 - (a) Solubility of gases
- (b) Thickness of the membranes
- (c) Pressure gradient
- (d) Concentration gradient
- (e) Reactivity of the gases
- [Bihar CECE 2006] 42. In Bhor's effect curve shift to right
 - (a) P₅₀ CO₂ decreases and P₅₀ O₂ increases
 - (b) P₅₀ CO₂ increases and P₅₀ O₂ decreases
 - (c) P_{50} CO_2 increases and P_{50} O_2 increases
 - (d) P₅₀ CO₂ increases and P₅₀ O₂ decreases and
- The figure given below shows a small part of human lung 43. where exchange of gases takes place. In which one of the option given below, the one part A, B, C or D is correctly identified along with its functions

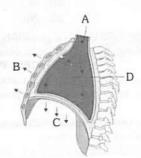

Options

[CBSE PMT (Pre.) 2011]

- (a) B : Red blood cell transport of CO2 mainly
- (b) C : Arterial capillary passes oxygen to tissues
- (c) A: alveolar cavity main site of exchange of respiratory gases
- (d) D : Capillary wall exchange of O2 and CO2 takes place here

- Reduction in pH of blood will
- [NEET (Phase-I) 2016]
- (a) Reduce the rate of heart beat
- (b) Reduce the blood supply to the brain
- (c) Decrease the affinity of hemoglobin with oxygen
- (d) Release bicarbonate ions by the liver
- When you hold your breath, which of the following gas 45. changes in blood would first lead to the urge to breathe
 - [AIPMT (Cancelled) 2015]
 - (a) Rising CO₂ concentration
 - (b) Falling CO2 concentration
 - (c) Rising CO2 and falling O2 concentration
 - (d) Falling O2 concentration
- In lungs there is definite exchange of ions between RBC and plasma. Removal of CO2 from blood involves [CPMT 2005]
 - (a) Influx of CI ions into RBC
 - (b) Influx of HCO3 ions into RBC
 - (c) Efflux of CI ions into RBC
 - (d) Efflux of HCO3 ions into RBC
- [NCERT; MP PMT 1993] In a minute normal man respires
 - (a) 10 times
- (b) 16 times
- (c) 30 times
- (d) 4 times
- The process by which chloride ions pass into R.B.C. and 48. bicarbonate ions pass out is called
 - [DPMT 1992; RPMT 1999; Kerala CET 2003]
 - (a) Bicarbonate shift
- (b) Chloride shift
- (c) Buffer system
- (d) Enzyme shift
- Following diagram indicates the mechanism of breathing. Identify all the parts A, B, C and D correctly [NCERT]

- (a) A Air expelled from lungs; B Ribs and sternum raised; C - Diaphragm contracted; D - Volume of thorax decreased
- (b) A Air expelled from lungs; B Ribs and sternum raised; C - Diaphragm relaxed; D - Volume of thorax decreased
- (c) A Air expelled from lungs; B Ribs and sternum return to original position; C - Diaphragm relaxed; D -Volume of thorax decreased
- (d) A Air entering into lungs; B Ribs and sternum raised; C - Diaphragm contracted; D - Volume of thorax raised
- Muscles which help in respiration are 50.
 - (a) Sternum and petrohyal (b) Sternohyal and petrohyal
 - (c) Jugal and tendons
- (d) None of these

- Of the following, the one which is an example of buffer system in blood is [Kerala PMT 2004]
 - (a) Haemoglobin and oxyhaemoglobin
 - (b) Oxygen and carbon dioxide
 - (c) Albumin and globulin
 - (d) Sodium bicarbonate and carbonic acid
- In a normal man to help the transport of \mathcal{O}_2 and \mathcal{CO}_2 52. properly, the blood is
 - (a) Slightly alkaline
- (b) Slightly acidic
- (c) Strongly alkaline
- (d) Strongly acidic
- In mammals how much CO_2 is transported as bicarbonates 53. of sodium and potassium in the blood [AIIMS 1993]
 - (a) 5-10 %
- (b) 10-90 %
- (c) 70-72 %
- (d) 90-95 %
- 54. A large proportion of oxygen is left unused the human blood even after its uptake by the body tissue. This O_2

[NCERT; CBSE PMT (Pre.) 2011]

- (a) Helps in releasing more O_2 to the epithelium tissues
- (b) Acts as a reserve during muscular exercise
- (c) Raises the pCO2 of blood to 75 mm of Hg
- (d) Is enough to keep oxyhaemoglobin saturation at 96%
- 55. Chloride shift is essential for the transport of

[CBSE PMT 1990]

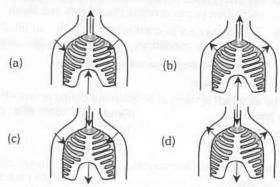

- (a) CO2 and O2
- (b) N₂
- (c) CO2
- (d) O2
- Which is true for CO2 concentration [Odisha JEE 2004]
 - (a) More in alveolar air than in expired air
 - (b) More in expired air than in alveolar air
 - (c) More in inspired air than in expired air
 - (d) More in inspired air than in alveolar air
- 57. The two waste products of oxidation in cells are
- - (a) CO_2 and N_2
- (b) C and O
- (c) CO2 and water
 - (d) Water and N_2
- The function of tracheal hair is to
- [BVP 2003]

- (a) Pass mucus out
- (b) Pass mucus in
- (c) Pass air out
- (d) Pass air in
- 59. The function of surfactant is/are
- [J & K CET 2012]
- (a) Facilitating lung expansion
 - (b) Maintaining the stable size of the alveoli
 - (c) To reduce the surface tension on the alveoli
 - (d) All the above
- 60. During cellular respiration the energy produced is stored in

The common immediate source of energy in cellular activity

- (a) Protoplasm
- (b) Cytoplasm
- (c) ATP
- (d) Nucleus

Exhalation is the process of expulsion of air through the 61. respiratory tract. Which figure correctly shows the process of exhalation

- Respiration is the physiological process in which 62.
 - (a) Breathing occurs
 - (b) Breathing and external respiration occur
 - Breathing, external respiration and cellular respiration
 - (d) Only inspiration occurs
- In rabbit the inspiration occurs by contraction of
 - (a) External intercostal muscles and muscles of the diaphragm
 - (b) Internal intercostal muscles and muscles diaphragm
 - (c) External intercostal muscles only
 - (d) Muscles of the diaphragm only
- Left shift of oxyhaemoglobin curve is noticed under

[EAMCET 2009]

- (a) Normal temperature and pH
- (b) Low temperature and high pH
- (c) Low pH and high temperature
- (d) Low pH and low temperature
- 65. Lungs do not collapse between breaths and some air always remains in the lungs which can never be expelled because

[NEET (Phase-II) 2016]

- (a) Pressure in the lungs is higher than the atmospheric
- (b) There is a negative pressure in the lungs
- (c) There is a negative intrapleural pressure pulling at the lung walls
- (d) There is a positive intrapleural pressure
- The partial pressure of oxygen in the alveoli of the lungs is

[NEET (Phase-II) 2016]

- (a) Less than that of carbon dioxide
- (b) Equal to that in the blood
- (c) More than that in the blood
- (d) Less than that in the blood

Control of breathing

- 1. How much amount of air can be inspired or expired during normal breathing [DPMT 2003; BVP 2004]
 - (a) 0.51
- (b) 2.51
- (c) 1.51
- (d) 5.51

(d) Enzyme

(c) Antioxidant

Rate of breathing is controlled by [Kerela CET 2005] 12. Breathing differs from respiration by [AFMC 1993] (a) The amount of freely available oxygen (a) Both are same and there is no difference (b) Carbon dioxide (b) Breathing refers to respiration in human beings whereas (c) Muscular function of the body respiration occurs in rest of the animals and plants (d) Stress (c) Breathing refers to chest movements due to inhalation Important concepts of respiration of O2 and exhalation of carbon dioxide whereas respiration refers to gaseous exchange [DPMT 1992] What is R.Q. for human fat (d) None of these (b) 0.655 (a) 0.673 The air which is taken in or given out during a single breath 3. (c) 0.703 (d) 0.825 [Kerala CET 2002; BHU 2008] [CPMT 1993] The form of energy used in respiration is (b) Vital air (a) Residual air (b) Electrical energy (a) Chemical energy (d) All of these (c) Tidal air (d) Radiant energy (c) Mechanical energy Combination of haemoglobin with O2 in lungs can be In human blood, the oxygen carrier is [CPMT 1994] promoted by (b) Meth-haemoglobin (a) Iron (a) Increasing CO2 concentration in blood (c) Haemocyanin (d) Haemoglobin (b) Increasing O₂ concentration in blood The toxic effect of carbon monoxide is due to its greater (c) Decreasing O2 concentration in blood as compared to oxygen, affinity for haemoglobin (d) Introducing CO in blood [BHU 2002] approximately by [RPMT 2005] Step of respiration are controlled by (b) 20 times (a) 2 times (a) Substrates (b) Enzymes (d) 1000 times (c) Hormone (d) Bile juice (c) 200 times During strenous exercise, which of the following change Respiration mechanism is controlled by 6. (a) Central nervous system (a) Glucose is converted into glycogen (b) Autonomic nervous system (c) Sympathetic nervous system (b) Glucose is converted into pyruvic acid (d) Parasympathetic nervous system (c) Starch is converted into glucose Which of the following conditions is responsible for increase 7. (d) Pyruvic acid is converted into lactic acid [CPMT 2005] in ventilation rate of lungs Which of the following blood vessels in the circulatory (a) Increase of CO₂ content in inhaled air system of frog has more oxygenated blood [AFMC 2006] (b) Increase of CO₂ content in exhaled air (a) Pulmocutaneous artery (b) Pulmocutaneous vein (c) Decrease of O2 content in inhaled air (c) Pulmonary artery (d) Precaval veins (d) Decrease of O2 content in exhaled air The respiratory centre in brain which controls inspiration Disorders of respiration system [CPMT 1993, 99; and expiration is situated in CBSE PMT 1994, 99; BHU 1995; AFMC 1995; After fast running, man has fast heart beat, slow pulse and RPMT 1995, 99, 2005, 06; MP PMT 1996; Pb. PMT 1999; shallow breathing, in such conditions he has AIIMS 2001; Kerala PMT 2010] (a) Oxygen debt (b) Poisoning due to lactic acid Respiratory and vomitting centres are located in (c) No pulmonary pressure [NCERT; MH CET 2002; DUMET 2009] (d) Weak heart (b) Cerebellum (a) Medulla oblongata Increased asthmatic attacks in certain seasons are related to (d) Pericardium 2. (c) Hypothalamus When CO2 concentration in blood increases, breathing [CBSE PMT 2007; MP PMT 2013] (a) Hot and humid environment [CPMT 2004] (b) Eating fruits preserved in tin containers (a) Slow and deep (b) Faster and deeper (c) Inhalation of seasonal pollen (c) Shallower and slow (d) Low temperature (d) There is no effect on breathing After taking a long deep breath we do not respire for some 3. [BHU 2005] Respiratory centre of brain is sensitive to seconds due to [NCERT; Odisha JEE 2004] (b) More O₂ in blood (a) More CO₂ in blood (a) More O₂ conc. in blood (d) Less O2 in blood (c) Less CO2 in blood (b) More CO2 conc. in blood Ascent of high mountains may cause altitude sickness in (c) Accumulation of blood in brain [NCERT; CPMT 2005] men. Prime cause of this is (d) All of these (a) Excess of CO2 in blood A substance that prevents or delays oxidation is (b) Decreased efficiency of haemoglobin [J & K CET 2005] (c) Decreased partial pressure of oxygen (b) Hormone (a) Bactericidal

(d) Decreased proportion of oxygen in air

UNIVERSAL BOOK DEPOT 1950

- The state during which the respiratory centre is inhibited is termed as [DPMT 1993]
 - (a) Asphyxia

(b) Suffocation

(c) Anoxia

- (d) Chocking
- 6. Ravi, who lived at sea level, had around 5 million RBC per cubic millimeter of his blood. Later when he lived at an altitude of 18,000 ft, showed around 8 million RBC per cubic millimeter of blood. This is an adaptation because

[AIEEE Pharmacy 2004; RPMT 2005]

- (a) At high altitude he ate more nutritive food
- (b) He had pollution free air to balance breathe
- (c) At high altitude O₂ level is less hence more RBCs were required to absorb enough oxygen
- (d) At high altitude there is more UV radiation which enhances RBCs production
- During rest, the metabolic needs of the body are at their minimum. Which of the following is indicative of this situation [AFMC 1994]
 - (a) Rate of breathing
- (b) Pulse rate
- (c) O2 intake and CO2 output (d) All of these
- 8. Cyanosis is
 - (a) Lack of oxygen in body fluids
 - (b) Difficult or heavy breathing
 - (c) Excess of carbon dixode in the body fluids
 - (d) 'Skin turning blue' due to excessive amount of deoxygenated haemoglobin in the skin blood vessels
- 9. Pneumotaxis centre is associated with
 - (a) Breathing
- (b) Respiration
- (c) Movement
- (d) Closure of glottis
- 10. Congestion of the lungs is one of the main symptoms in

[Kerala PMT 2011]

- (a) Hypotension
- (b) Coronary artery disease
- (c) Angina
- (d) Heart failure
- (e) Atherosclerosis
- 11. When O_2 is inadequate during respiration, the condition is called [BVP 2000; WB JEE 2011; Odisha JEE 2012]
 - (a) Anoxia
- (b) Pleurisy
- (c) Asphyxia
- (d) Hypoxia
- 12. The oxygen toxicity is related with
- [BHU 2004]

- (a) Blood poisoning
 - (b) Collapse of alveolar walls
 - (c) Failure of ventilation of lungs
 - (d) Both (a) and (b)
- 13. The diabetic patient shows
 - (a) High respiratory quotient (b) Low respiratory quotient
 - (c) Zero respiratory quotient (d) None of these
- The 'blue baby' syndrome results from [CBSE PMT 2006]
 - (a) Excess of dissolved oxygen
 - (b) Excess of TDS (total dissolved solids)
 - (c) Excess of chloride
 - (d) Methaemoglobin
- 15. Asthma is characterised by [NCERT; Odisha JEE 2011]
 - (a) Spasm in bronchial muscle
 - (b) Alveolar wall degradation
 - (c) Pain in lungs
 - (d) Damage in diaphragm

16. In which disease, due to flattening of tracheal vessels, alveoli are deprived of oxygen [NCERT; GUJCET 2007]

Or

Name the pulmonary disease in which alveolar surface area involved in gas exchange is drastically reduced due to damage in the alveolar walls

[AIPMT 2015]

- (a) Bronchitis
- (b) Asthma
- (c) Pneumonia
- (d) Emphysema
- Blood analysis of a patient reveals an unusually high quantity of carboxyhaemoglobin content. Which of the following conclusions is most likely to be correct [CPMT 2004]
 - (a) Carbon dioxide
- (b) Carbon monoxide
- (c) Carbon disulphide
- (d) Chloroform

Q NCERT

Exemplar Questions

- Respiration in insects is called direct because [NCERT]
 - (a) The tissues exchange ${\rm O_2/CO_2}$ directly with the air in the tubes
 - (b) The tissues exchange O₂/CO₂ directly with coelomic fluid
 - (c) The tissues exchange O₂/CO₂ directly with the air outside through body surface
 - (d) Tracheal tubes exchange O_2/CO_2 directly with the haemocoel which then exchange with tissues
- Regarding the functions of our respiratory system, mark the wrong entry
 - (a) Humidifies the air
- (b) Warms up the air
- (c) Diffusion of gases
- (d) Cleans up the air
- A person suffers punctures in his chest cavity in an accident, without any damage to the lungs its effect could be [NCERT]
 - (a) Reduced breathing rate
 - (b) Rapid increase in breathing rate
 - (c) No change in respiration
 - (d) Cessation of breathing
- Mark the true statement among the following with reference to normal breathing [NCERT]
 - (a) Inspiration is a passive process where as expiration is active
 - (b) Inspiration is a active process where as expiration is passive
 - (c) Inspiration and expiration are active processes
 - (d) Inspiration and expiration are passive processes
- A person breathes in some volume of air by forced inspiration after having a forced expiration. This quantity of air taken in is

 [NCERT]
 - (a) Total lung capacity
- (b) Tidal volume
- (c) Vital capacity
- (d) Inspiratory capacity
- Mark the incorrect statement in context to O₂ binding to Hb
 [NCERT]
 - (a) Higher pH
- (b) Lower temperature
- (c) Lower pCO₂
- (d) Higher PO2

- Mark the correct pair of muscles involved in the normal breathing in humans [NCERT]
 - (a) External and internal intercostals muscles
 - (b) Diaphragm and abdominal muscles
 - (c) Diaphragm and external intercostals muscles
 - (d) Diaphragm and internal intercostals muscles
- Incidence of Emphysema a respiratory disorder is high in 8. [NCERT] cigarette smokers. In such cases
 - (a) The bronchioles are found damaged
 - (b) The alveolar walls are found damaged
 - (c) The plasma membrane is found damaged
 - (d) The respiratory muscles are found damaged
- Respiratory process is regulated by certain specialized 9. centres in the brain. One of the following listed centres can reduce the inspiratory duration upon stimulation
 - (a) Medullary inspiratory centre (b) Pneumotaxic centre
 - (c) Apneustic centre
- (d) Chemosensitive centre
- CO2 dissociates from carbamino haemoglobin when 10.

[NCERT]

- (a) pCO2 is high and pO2 is low
- (b) pO2 is high and pCO2 is low
- (c) pCO2 and pO2 are equal
- (d) None of the above
- Identify the correct and incorrect match about respiratory 11. volume and capacities and mark the correct answer
 - Inspiratory capacity (IC) = Tidal Volume + Residual volume
 - (ii) Vital Capacity (VC) = Tidal Volume (TV) + Inspiratory Reserve Volume (IRV) + Expiratory Reserve Volume
 - (iii) Residual Volume (RV) = Vital Capacity (VC) -Inspiratory Reserve Volume (IRV)
 - (iv) Tidal Volume (TV) = Inspiratory Capacity (IC) -Inspiratory Reserve Volume (IRV)

[NCERT]

- (a) (i) Incorrect, (ii) Incorrect, (iii) Incorrect, (iv) Correct
- (b) (i) Incorrect, (ii) Correct, (iii) Incorrect, (iv) Correct
- (c) (i) Correct, (ii) Correct, (iii) Incorrect, (iv) Correct
- (d) (i) Correct, (ii) Incorrect, (iii) Correct, (iv) Incorrect
- The oxygen haemoglobin dissociation curve will show a 12. [NCERT] right shift in case of
 - (a) High pCO₂
- (b) High pO₂
- (c) Low pCO2
- (d) Less H+ concentration
- 13. Match the following and mark the correct options

Animal

Repiratory organ

- A. Earthworm
- Moist cuticle
- B. Aquatic Arthropods
- Gills
- C. Fishes
- Lungs
- D. Birds/Reptiles
- Trachea

Options

[NCERT]

- (a) A-ii, B-i, C-iv, D-iii
- (b) A-i, B-iv, C-ii, D-iii
- (c) A-i, B-iii, C-ii, D-iv
- (d) A-i, B-ii, C-iv, D-iii

Critical Thinking

Objective Questions

- Which animal has unpaired lungs
 - (a) Monkey
- (b) Whale
- (c) Some frogs (d) Some snakes
- Mammalian lungs have enormous number of minute alveoli [AFMC 1994; MP PMT 1995] (air sacs). It is to allow
 - (a) More space for increasing the volume of inspired air
 - (b) More surface area for diffusion of gases
 - (c) More spongy texture for keeping lungs in proper shape
 - (d) More nerve supply to keep organs active when working
- True organ of sound production in birds is [Kerala CET 2003] 3.
 - (a) Larynx
- (b) Sound box
- (c) Vocal sac
- (d) Syrinx
- The nerve impulses which stimulate the intercostal muscles and diaphragm and thus permit breathing, originate in the

[AIIMS 1992]

- (a) Cerebellum
- (b) Pons
- (c) Hypothalamus
- (d) Medulla oblongata
- Number of alveoli in human lung is about [Odisha JEE 2012]
 - (a) One million
- (b) More than two millions
- (c) More than five millions
- (d) More than seven millions
- Which of the following statements is not true

[Kerala PMT 2007]

- (a) The partial pressure of oxygen in deoxygenated blood is 40 mm Hg
- (b) The partial pressure of oxygen in oxygenated blood is 95 mm Hg
- The partial pressure of oxygen in the alveolar air is 104 mm Hg
- The partial pressure of carbon dioxide in the alveolar air is 40 mm Hq
- The partial pressure of carbon dioxide in deoxygenated blood is 95 mm Hg
- Which option is completely correct for the given statements 7. Statement 1 - The nerve impulse ordered by respiratory centre passes through nerve to the diaphragm and the intercostal muscles and regulates respiration

Statement 2 - Respiratory centres scatterly located in the brain stem gives of rhythmic stimuli to diaphragm and respiratory muscle and regulate respiration [GUJCET 2014]

- (a) First statement is correct and second statement is wrong
- (b) First statement is wrong and second statement is correct
- (c) Both of the statements are wrong
- (d) Both of the statements are correct
- The impulse for voluntary muscles for forced breathing starts
 - (a) Medulla
- (b) Vagus nerve
- (c) Cerebrum
- (d) Cerebellum

ı	
ı	HARVESCAL
ı	STATE COLUMN
	BOOK DEPOT 1960

- How much CO2 is present per 100 ml of venous blood
 - (a) 52.1 ml
- (b) 3.7 ml
- (c) 40 ml
- (d) 20 ml
- 10. Which of the following statements are true / false
 - The blood transports CO2 comparatively easily because of its higher solubility
 - Approximately 8.9% of CO2 is transported being dissolved in the plasma of blood
 - C. The carbon dioxide produced by the tissues, diffuses passively into the blood stream and passes into red blood corpsucles and react with water to form H2CO3
 - D. The oxyhaemoglobin (HbO₂) of the erythrocytes is basic
 - E. The chloride ions diffuse from plasma into the erythrocytes to maintain ionic balance

[Kerala PMT 2006]

- (a) A, C and E are true, B and D are false
- (b) A, C and E are false, B and D are true
- (c) A, B and D are true, C and E are false
- (d) A, B and D are false, C and E are true
- (e) A, B and C are true, D and E are false
- Which one of the following is the correct statement for respiration in humans [NCERT; CBSE PMT (Pre.) 2012]
 - (a) Cigarette smoking may lead to inflammation of bronchi
 - (b) Neural signals from pneumotoxic centre in pons region of brain can increase the duration of inspiration
 - (c) Workers in grinding and stone-breaking industries may suffer, from lung fibrosis
 - (d) About 90% of carbon dioxide (CO2) is carried by haemoglobin as carbamino haemoglobin
- 12. Concentration of carbonic acid does not increase in blood due to the presence of
 - (a) Na+
- (c) Ca++
- (d) Mq++
- 13. A pyrophosphate cleavage takes place when [CPMT 1998]
 - (a) ATP is converted into AMP
 - (b) ATP is converted into ADP
 - (c) ADP is converted into AMP
 - (d) AMP is converted into ATP
- Haemoglobin is having maximum affinity with

[CPMT 1995; MP PMT 1999; RPMT 1999]

- (a) CO₂
- (b) CO
- (c) O₂
- (d) NH₃
- When a man inhales air containing normal concentration of O2 as well as CO he suffers from suffocation because

[AIIMS 1993; BVP 2003]

- (a) CO reacts with O₂ reducing its percentage in air
- (b) Haemoglobin combines with CO instead of O_2 and the product cannot dissociate
- (c) CO affects diaphragm and intercostal muscles
- (d) CO affects the nerve of the lungs

- Which two of the following changes (A-B) usually tend to occur in the plain dwellers when they move to high altitudes (3500 m or more)
 - (A) Increase in red blood cell size
 - (B) Increase in red blood cell production
 - (C) Increased breathing rate
 - (D) Increase in thrombocyte count

Changes occurring are

[CBSE PMT (Pre.) 2010]

- (a) (A) and (B)
- (b) (B) and (C)
- (c) (C) and (D)
- (d) (A) and (D)
- If a person breathes with maximal effort but with his nose and mouth closed, the alveolar pressure can be decreased to as low as
 - (a) -80 mm Hg
- (b) +10 mm Hg
- (c) -180 mm Hg
- (d) -250 mm Ha
- 18. Rate of respiration is directly proportional to [CPMT 1993]
 - (a) Concentration of oxygen in blood
 - (b) Concentration of carbon dioxide in blood
 - (c) Oxygen in trachea
 - (d) Diaphragm expansion
- 19. If a man from sea coast goes to Everest peak then

[CPMT 1996; MP PMT 2002]

- (a) His breathing and heart beat will increase
- (b) His breathing and heart beat will decrease
- (c) His respiratory rate will decrease
- (d) His heart beat will decrease
- Exposure to carbon monoxide (from coal gas) is extremely dangerous and can kill a patient because

[NCERT; KCET 1996]

[CPMT 1992]

- (a) The compound carboxyhaemoglobin (COHb) it forms with heamoglobin can gradually clot the blood resulting in circulatory failure
- (b) COHb reduces the ability of blood for transport oxygen by ruputring a vast majority of erythrocytes
- COHb greatly modifies the structure of haemoglobin, thus making it lose its affinity for oxygen
- (d) None of the above
- 21. Blood does not transport oxygen in

 - (a) Cockroach
- (b) Earthworm
- (c) Frog's tadpole
- (d) Mammalian foetus
- Forced deep breathing for a few minutes by a person sitting at rest may be followed by a temporary cessation of breathing. This is due to
 - (a) Too much O_2 in the blood
 - (b) Too much CO₂ in the blood
 - (c) Very little CO2 in the blood
 - (d) Both too much O_2 and very little CO_2 in the blood
- Hamburger phenomenon is also known as

[CMC Vellore 1993; AIIMS 1993; BHU 2001, 08; JIPMER 2002; MP PMT 2007, 09, 10]

- (a) Hydrogen shift mechanism
- (b) Chloride shift mechanism
- (c) Carbonic acid shift mechanism
- (d) Sodium-potassium pump

- In an accident, a man dies immediately although their was no injury to brain, kidney, stomach and heart, The probable cause of death may be
 - (a) Coagulation of RBC
 - (b) Digestion stopped
 - (c) Diaphragm got punctured
 - (d) Larynx got punctured
- IMP PMT 20001 Buccopharyngeal respiration in frog
 - (a) Is increased when nostrils are closed
 - (b) Stops when there is pulmonary respiration
 - (c) Is increased when it is catching fly
 - (d) Stops when mouth is opened
- Name the chronic respiratory disorder caused mainly by [NEET (Phase-I) 2016] cigarette smoking
 - (a) Emphysema
- (b) Asthma
- (c) Respiratory acidosis
- (d) Respiratory alkalosis
- Asthma may be attributed to 27.
- [NEET (Phase-I) 2016]

- (a) Bacterial infection of the lungs
 - (b) Allergic reaction of the mast cells in the lungs
 - (c) Inflammation of the trachea
 - (d) Accumulation of fluid in the lungs
- Which of the following statement(s) is/are correct 28.

[WB JEE 2016]

- (a) Silicosis is the result of exposure to silica that causes permanent lung damage and death
- (b) Transportation of gases and digested food materials in the body of higher animals causes muscle weakness and fatigue
- (c) ADH is a neurohypophysial hormone that regulates body water
- (d) Myasthenia gravis is a neuromuscular disease that is mediated by circulatory system

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- If both the assertion and reason are true but the reason is (b) not a correct explanation of the assertion
- If the assertion is true but the reason is false (c)
- If both the assertion and reason are false (d)
- If the assertion is false but reason is true (e)
- Aerobic animals are not truely aerobic. Assertion
 - They produce lactic acid anaerobically. Reason
- Coughing and sneezing are necessary. 2. Assertion
- Coughing and sneezing are reflex actions. Reason
- Most fish when out of water, die of 3. Assertion suffocation.
 - Atmospheric air contains far less oxygen Reason content than the dissolved oxygen in water.

Symptoms of emphysema develops when a 4. Assertion person living on plains ascends and stays

on a mountain.

Air pressure and partial pressure of oxygen Reason

falls with the rise in altitude.

Assertion If there is no air in trachea, it will collapse. 5.

Trachea is having the cartilagenous ring. Reason

[AIIMS 1999]

to muscular Inspiration occurs due Assertion

relaxation.

During inspiration, the diaphragm and Reason intercostal muscle external

> [AIIMS 1995] simultaneously.

Respiratory Syndrome 7. Assertion Severe Acute (SARS) originated in China.

> China is the most populated country of the [AIIMS 2003] world.

8. Assertion Blood of insects is colourless.

Reason

- The blood of insect does not play any role Reason [AIIMS 1994] in transport of oxygen.
- Gill-lamellae in aquatic animals help in 9. Assertion exchange of gases.
 - Each gill lamella carries many blood Reason capillaries.
- In mammals, complex respiratory system 10. Assertion has developed.
- Mammalian skin is impermeable to gases. Reason Insects develop a complex system of air
- Assertion 11. tubes called trachea for respiratory purpose.
 - Exchange through body surface is not Reason possible in insects.
- Assertion Aerobic respiration involves the exchange of respiratory gases twice.
 - Exchange occurs from lung to heart and Reason then heart to lung.
- Carbonic anhydrase is present in the Assertion erythrocytes.
 - In erythrocytes the carbon dioxide combine Reason with water and is transported.

[Kerala PMT 2006]

Answers and Solutions

Respiratory organs

- 3. (d) Haemolymph is found in insect blood which is colourless.
- 7. (c) In forced expiration internal intercostal muscles and some abdominal muscles contract to reduce the volume of thorax.
- (b) Inside the larynx there are vocal cords. These are two 10. pairs of fold of mucous membrane that extend into the lumen of the larynx from the sides.
- (d) The pharynx provides passage to both air and food. 12.
- 14. (a) In man, the left lungs has two lobes, superior lobe and inferior lobe, the right lungs has three lobes superior lobe, middle lobe and inferior lobe.
- 18. (d) Earthworm has a closed circulatory system. Hb dissolved in plasma of blood acts as a respiratory pigment, transporting O_2 to the body tissues.
- 23. (c) In rabbit, the left lung is divided into two lobes, left anterior and left posterior whereas the right lung has four lobes, anterior azygous, right anterior right posterior and posterior azygous.
- 24. (b) Each lung is enclosed in two membranes called pleurae. The outer covering is adhered to chest wall and diaphragm and is called parietal pleura. The inner covering membrane, which closely covers the lung, is called visceral pleura.
- 27. (c) Haemocyanin is copper containing pigment. It is respiratory pigment of Prawn. Haemocyanin becomes blue when oxygenated and colourless during deoxygenation.
- (d) It serves to close the glottis during deglutition thereby 30. preventing entry of food into respiratory tract.
- (a) Diaphragm has no role in the respiration in frog but in 31. mammals it increase the surface area for respiration.
- (d) Presence of diaphragm is mammalian character, which 33. is dome-shaped partition that separates the thoracic and abdominal cavities.

Pulmonary volumes and capacities

(c) Vital capacity of lungs to expire maximum volume of air after a deep inspiration. The largest quantity of air that can be expired after a maximal inspiratory. Vital capacity is equal the sum of the tidal complemental and supplemental air $(500 + 3100 + 1200 = 4800 \, ml)$.

- (a) The volume of air inspired and expired with each normal breath is tidal volume, which is approximately 500 ml.
- 12. (d) The residual volume is that part of the air in the lung which cannot be exhaled; it represents the remaining volume of lung when forced exhalation of the lung has occurred.

Process of respiration

- (a) More active tissue has much lower PO₂. Therefore much more oxygen is released from oxyhaemoglobin in the active tissue.
- (b) The gaseous exchange is the simple diffusion of oxygen from alveolar air into the blood and diffusion of CO₂ from blood to alveolar air.
- (a) Oxygen tends to displace CO₂ so that the curve shifts more to the right.
- (c) This pump is connected through a tube to an external machine for inflating or deflating it with helium.
- 13. (d) Nearly 20-25 percent of CO₂ is transported by RBCs, whereas, 70 percent of it is carried as bicarbonates. About 7 percent of CO₂ is carried as dissolved state in plasma.
- 25. (a) Under a given oxygen concentration in blood, dissociation of oxyhaemoglobin will increase if pH of blood falls.
- 28. (a) O₂ dissociation curve for haemoglobin is sigmoid in shape.
- 29. (b) During expiration diaphragm relaxes and becomes dome-shaped thereby reducing intrathoracic volume to pass out the air from body.
- 31. (c) During pulmonary respiration mouth remains closed all the time whereas nostrils are opened only when air is taken in or passed out i.e. during first stroke of inspiration and second stroke of expiration respectively.
- 32. (a) In anaerobic respiration pyruvate undergoes two types of incomplete reduction. In one case it results in the production of ethyl alcohol (Yeast) and in other it produces lactic acid (muscles).
- 38. (b) Billirubin is an orange pigment that is one of the end product of haemoglobin breakdown in the hepatocyte and is excreted as a waste material in bile.
- (d) In the form of H₂CO₃ dissolved in plasma and NaCO₃ and KHCO₃ as bicarbonates.
- 43. (c) A is the alveolar cavity which is the main site of exchange of respiratory gases.
- **45.** (a) Rise in CO_2 concentration is detected by chemosensitive area activates inspiratory centre in Medulla oblongata, which lead to urge of breathing. Role of O_2 concentration is non significant.
- 47. (b) During normal breathing the respiratory movement in 25 years old is about 16/min.

- 48. (b) To maintain electrostatic neutrality of plasma, many chloride ions diffuse from plasma into RBCs and bicarbonate ions pass out. The chloride content of RBCs increases when oxygenated blood becomes deoxygenated. This termed as chloride shift or Hamburger shift.
- 50. (b) Sternohyal and petrohyal helps in respiration of frog. Contraction of sternohyal muscle during breathing in frog lowers floor of oral cavity. While contraction of petrohyal muscle during breathing in frog raises the floor of buccal cavity.
- 53. (c) 7% of CO_2 is transported in dissolved form in the plasma, 23% as carbaminohaemoglobin and 70% in the form of bicarbonates.
- **54.** (b) Our tissues are able to utilise only 25% of O_2 carried by artetrial blood. Our venous blood is still 75% saturated with O_2 . This O_2 acts as a reserve during muscular exercise.
- 57. (c) Respiration is the process of oxidation by which food material are oxidized and produce CO₂ and water as waste product.
- 59. (d) Surfactant is a lipoprotein secreted by surfactant secreting cells, which form part of alveolar epithelium. This tends to reduce the surface tension of fluid lining the alveoli and thus facilitates lung expansion and also maintains the stable size of the alveoli.
- 60. (c) In the form of phosphate bond energy.
- 63. (a) During inspiration the diaphragm and external intercostal contract simultaneously. This moves the lateral thoracic walls outward and upward.
- 66. (c) PO2 in Alveoli is 104, while in oxygenated blood, it is 95.

Control of breathing

- (a) Tidal volume is the volume of air breathed in and out during normal respiration and is equal to about 500 ml or 0.5l
- (c) Tidal volume is the volume of air inspired or expired with each breath. This is about 500 ml in an adult person.
- **6.** (a) Because the respiratory centres are located in the medulla oblongata and pons varoli in the hind brain.
- (a) Breathing is controlled by pneumotaxic and apneustic centres in pons varoli and expiratory and inspiratory centres in medulla oblongata.
- 10. (b) A chemosensitive area located close to the respiratory centre in medulla is highly sensitive to changes in PCO₂ or pH of the blood.

Important concepts of respiration

- (d) Hemoglobin, an iron containing red pigment is responsible for transport of O₂ and CO₂ in human blood.
- 4. (c) The affinity of haemoglobin for CO is approximately 210 times greater than O_2 .
- 6. (b) The oxygenated blood from two lungs is collected by right and left pulmmonary veins, which unite to form a common pulmonary vein (Pulmocutaneous vein) which open directly into the left auricle, on the dorsal side.

Disorders of respiration system

- (a) Rate of O₂ supply by lungs into muscles falls down during active work or in exercise. Muscles accumulate lactic acid and slowly breathing becomes hard so as to increase O₂ intake in lungs. This stage is called oxygen debt.
- (c) Because plants release pollen grain a fix time and it is generally March-April or Aug. – Sep.
- (d) Cyanosis is blueness of skin and occurs due to large amount of deoxygenated haemoglobin in cutaneous vessels.
- 12. (c) Oxygen toxicity develops when pure oxygen is breathed in for a prolonged period. This is formed due to progressive failure of ventilation of lungs.
- (b) Diabetic patient shows low R.Q. due to the increased dissimilation of fats and decreased dissimilation of carbohydrates.
- 16. (d) Emphysema is the respiratory disorder in which the septa between the alveoli are destroyed and much of the elastic tissue of the lungs is replaced by connective tissue. It is generally caused by a long term irritation. Air pollution, occupational exposure to industrial dust and cigarette smoke are the most common irritants.

Critical Thinking Question

- 1. (d) Some snakes have only one bronchus and the right lung.
- 2. (b) In mammalian lungs each alveolar duct ends in a passage, called atrium, which leads into a number of rounded alveolar sacs. Each alveolar sac is studded with a large number of air sacs or alveoli. Alveoli are the sites of respiration.
- (d) Syrinx is a sound producing organ in birds.
- 4. (d) The respiratory centres that control the breathing mechanism are present in medulla oblongata. These respiratory centres are expiratory centre and inspiratory centre.
- 5. (d) The number of alveoli in human lungs has been estimated to be approximately 750 million, exposing a surface area of nearly $100 m^2$.

- 7. (d) The nerve impulse ordered by respiratory centre passes through vagus nerve to the intercostal muscles and diaphragm and regulates respiration. The respiratory centres are scattered in brain stem and are constantly giving off rhythmically stimuli to the respiratory muscles in virtue of their inherent rhythm causing inspiration and expiration.
- (b) Every 100 ml of blood receives an average 3.7 ml of CO₂ from tissues.
- 15. (b) Carbon monoxide has 210 times more affinity with haemoglobin as compared to O₂ and forms a stable compound.
- 18. (b) Due to direct chemical control on respiratory centres, CO₂ stimulates respiratory centres in CNS.
- 19. (a) At high altitude, PO_2 of alveolar air falls because of low O_2 tension of tissues. So, O_2 is absorbed very quickly from alveoli, thus, increasing breathing rate. Heart beat also increases to supply required amount of O_2 to tissues.
- 20. (c) COHb is a stable compound formed by the combination of carbon monoxide and haemoglobin. It has more affinity than oxygen.
- 21. (a) Due to absence of respiratory pigment.
- 22. (d) Deep breathing rises the O₂ level of the blood. By excess formation of oxyhaemoglobin the acidity of blood increases. To control it, more of free CO₂ changes into bicarbonates and the free CO₂ level in the blood decreases. So due to lack of stimulant for inspiratory centre cessation of breathing takes place, after some time O₂ is consumed by the tissues and rise in CO₂ stimulates breathing again.
- 23. (b) To maintain electrostatic neutrality of plasma, many chloride ions diffuse from plasma into RBCs and bicarbonate ions pass out. The chloride content of RBCs increase when oxygenated blood become deoxygenated. This is termed as chloride shift or Hamburger phenomenon.
- 25. (d) This process occurs through nares and mouth and gullet are kept closed during the process.
- 28. (acd) Silicosis is an occupational lung disease that causes progressive respiratory failure and death. ADH is synthesized from hypothalamic nuclei and are responsible for water absorption by nephron. Myasthenia gravis is an autoimmune disorder mediated by antibodies.

Assertion and Reason

- (a) In most animals, tissue oxidation are carried out by aerobic respiration. But sometimes in aerobically respiring animals, anaerobic metabolism take place in certain tissues like skeletal muscles which do not immediately get as much oxygen as in necessary for their acid anaeorbically from glucose during vigorous movements.
- 2. (b) Coughing and sneezing are necessary to take place because these reactions serve to keep the air passages free from foreign matter. Coughing is a reflex action under nervous control. The minute receptors found in the wall of trachea, bronchi, bronchioles and alveoli are highly sensitive to foreign matter (smoke, dust etc.) Like coughing, sneezing is also a reflex action triggered because of irritation to nasal passages. In this, sensory impulses travel from nasal passages to the medulla through trigeminal nerves. The reaction involves the same series of events as in cough reflex, but the air explodes out both through nose and mouth, expelling the foreign matter from nasal passages.
- 3. (c) Although atmospheric air contains far more oxygen content than the water (air contain 21% oxygen and water contains 0.5-0.9% oxygen by volume depending on the temperature), still most fish when out of water die of suffocation due to lack of oxygen. When fish is taken out of water the gills stick together thereby reducing the surface area. Reduced surface area lowers gas exchange so death ensues.
- 4. (e) When a person living on plains ascend and stays on a mountain above 8000 feet from the sea level, he develops symptoms of mountain sickness which includes breathlessness, headache, dizziness, irritability, nausea, vomiting, mental fatigue and a bluish tinge on the skin, nails and lips.
 - We know that with the rise in altitude, the barometric pressure and consequently the partial pressure of oxygen falls in the atmospheric air. This lowers the alveolar partial pressure of oxygen which causes reduction in the diffusion of oxygen from the alveolar air to the blood. So oxygenation of blood is decreased progressively, which produces the symptoms of mountain sickness, Emphysema.
- (e) There is no air in trachea, it does not collapse due to the presence of C-shaped narrow cartilaginous ring or discs.
- 6. (e) Inspiration is the result of muscular contraction. The diaphragm and external intercostal muscle contracts simultaneously. The lateral thoracic wall moves outward and upward.

- 7. (b) The world health organization (WHO) reported China as the origin place of SARS. Several other countries have reported SARS cases after travel to China and its nearby areas/countries in Asia or close contact with a person affected with SARS. Microbiologists of Hongkong Central University initially detected a virus metapneumovirus and identified as corona virus causative agent of SARS. It is very known fact that the China is the most populated country. This fact cannot be correlated with SARS
- 8. (b) Blood is colorless in insects. Insects have tracheal respiration. It is carried on by an extensive system of inter-communicating tubes called trachea.
- 9. (a) Gills are the main respiratory organs of aquatic animals. Each gill bears rows of comb-like, soft, thin gill-filament, each gill-filament bears many flat, parallel membrane-like gill-lamellae. Each gill lamella carries many blood capillaries. Water taken through the mouth, is made to flow from the pharynx in a single direction between the gill lamella. Blood flows in the capillaries of gill-lamella in a direction opposite to the flow of water over the lamellar surfaces. This greatly helps in the gaseous exchange across the lamellar membrane between the capillary blood and the flowing water.
- 10. (b) Mammalian skin in impermeable so that water loss through it is minimized. But mammals need far more oxygen to maintain their high metabolic rates than lower animals; so they need a more extensive respiratory surface. Thus a complex respiratory system has evolved in mammals to meet this need. The mammalian respiratory system consists of the nasal cavity, nasopharynx, larynx, trachea, bronchi, bronchiole and lungs.
- 11. (a) As the integument of insect is thick and impermeable to minimize lose of body water, they can not carryout gas exchange through their body surface. To overcome this difficulty they have developed a complex system of air tubes called trachea to reach the air directly near the tissue cells. Each trachea communicates with the exterior through openings in the body wall.
- 12. (c) Aerobic respiration involves the exchange of respiratory gases at two places in multicellular animals-one between the body surface and surrounding medium, the other between the individual cells and the extra cellular fluid. Lungs are involved in the first step of exchange, but not the heart.
- 13. (a)

Answers and Solutions

1	d	2	d	3	b	4	d	5	C
6	a	7	C	8	С	9	d	10	d
11	a	12	a	13	С	14	b		100

- 10. (d) One molecule of the haemoglobin has 4 haem groups and each of them is capable of taking up one molecule of O2.
- Spirometry is the process of recording the changes in the volume movement of air into and out of lung and the instrument used for the purpose is called spirometer or respirometer.

This system is concerned with the circulation of body fluids to distribute various substances to various body parts.

Functions of Circulatory System

- (1) Transport of various substances such as nutrients, waste products, respiratory gases, metabolic intermediates (Such as lactic acid from muscle to liver), vitamins, hormones etc.
- (2) Regulation of body *pH* by means of buffer, body temperature homeostasis, water balance etc.
- (3) Prevention of diseases by means of antibodies and antitoxins.
 - (4) Support or turgidity to certain organs like penis and nipples.

Types of Circulation

Circulatory system in various groups of animals can be classified as follows:

- Intracellular circulation: Occurs inside the individual cells where the distribution of substances is through cyclosis of cell cytoplasm. Example – Protozoans.
- (2) Extracellular circulation: When the distribution of the substances occurs inside the body through extracellular or intracellular fluids. This is of following types –
- (i) Extra organismic circulation: Canal system in porifera, water vascular system in Echinoderms and gastrovascular system in coelenterates.
- (ii) Intra-organismic circulation: It involves circulation of body fluids. It is of following types –
- (a) Parenchymal circulation: In platyhelminthes, the fluid filled spaces present in the mesodermal parenchyma tissue between body wall and internal organs are used in the distribution of substances.
- (b) Coelomic circulation: Coelomic fluid is concerned with the transport of substances. Example – pseudocoelomic fluid in the roundworms and haemolymph in Arthropods.

(c) Blood vascular system: It contains blood and a pumping structure (heart) for circulation of materials inside the body. It is open circulatory system and closed circulatory system.

Table: 5.3-1 Differences between open and closed circulatory system

S.N.	Open circulatory system	Closed circulatory system	
1.	In open circulatory system blood flows through large open spaces and channels called lacunae and sinuses among the tissues.	In closed circulatory system blood flows through a closed system of chambers called heart and blood vessels.	
2.	Tissues are in direct contact with the blood.	Blood does not come in direct contact with tissue.	
3.	Blood flow is very slow and blood flow is quite rapid blood has very low pressure.		
4.	Exchange of gases and nutrients takes place directly between blood and tissues.	Nutrients and gases pass through the capillary wall to the tissue fluid from where they are passed on to the tissues.	
5.	Less efficient as volume of blood flowing through a tissue cannot be controlled as blood flows out in open space.	More efficient as volume of blood can be regulated by the contraction and relaxation of the smooth muscles of the blood vessels.	
6.	Open circulatory system is found in higher invertebrates like most arthropods such as prawn, insects, etc., and in some molluscs (snails, clams, oyster).	nates found in echinoderms, some molluscs, (squids) annelids and in all vertebrates.	
7.	Respiratory pigment, if present, is dissolved in plasma; RBCs are not present.	Respiratory pigment is present and may be dissolved in plasma but is usually held in RBCs.	

Blood circulation in vertebrates

Blood circulation was discovered by William harvey. In case of vertebrates, blood circulation is of closed type, which can be grouped into two categories:

(1) Single circulation

(2) Double circulation

Table : 5.3-2 Differences between single and double circulation

S.N.	Single circulation	Double circulation	
1,	Blood flows only once through the heart in a complete cycle. Auricle Ventricle Tissues Gills	Blood flows in two circuit pulmonary and systemic. Pulmonary vein Right Left Venacava auricle auricle Tissues Right Left Ventricle Ventricle Pulmonary artery Dorsal aorta	
2.	Heart pumps only deoxygenated blood, hence called Venous Heart.	Heart pumps both deoxygenated and oxygenated blood to lungs and body respectively, hence called arteriovenous heart.	
3.	Blood is oxygenated in gills.	Blood is oxygenated in lungs.	
4.	Less efficient as gill capillaries slow down the blood flow. So, the body receives blood at a low pressure which decreases the rate of O_2 supply to the cells i.e. keeps the metabolic rate low.	More efficient as blood flows at higher pressure, especially in birds and mammals, which increases the rate of food and O_2 supply to the cells and also rapid removal of wastes from them i.e. provides a higher metabolic rate.	
5.	Found only in fishes, petromyzon.	Found in dipnoi, amphibians, reptiles, birds and mammals.	

Double circulation in mammals can be divided into three parts:

- (i) Cardiac circulation : The amount of blood present in the heart. Its value is 8%.
- (ii) **Pulmonary or lesser circulation :** The amount of blood present in the surrounding of lungs and pulmonary blood vessels. Its value is 12%.
- (iii) **Systemic or greater circulation :** The amount of blood which circulates in the rest part of the body. Its value is 80%. It can be divided into three parts –

Arterial circulation - 15%

Capillary circulation - 5%

Venous circulation - 60%

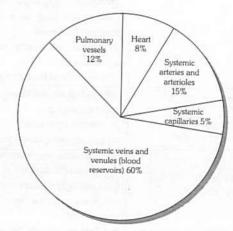

Fig: 5.3-1 Distribution of blood volume in different part of circulatory system

Heart

The form, structure and function of heart exhibits much variation. The characteristics of heart of fishes, amphibians, reptiles, birds and mammals is presented in the following table.

Table: 5.3-3 Heart of vertebrates

S.No.	Class of vertebrates	Characteristics	Example	Diagram
1.	Pisces (= Branchial heart), Cyclostomata	Thick, muscular, made of cardiac muscles, has two chambers (i) auricle and (ii) ventricle. The heart is called venous heart since it pumps deoxygenated blood to gills for oxygenation. This blood goes directly from gills to visceral organs (single circuit circulation). A sinus venosus and conus arteriosus is present. Lung fishes have only one auricle and one ventricle.	Labeo Scoliodon	Conus arteriosus Ventricle Auricle Sinus venosus
2.	Amphibians, Lung fish	Heart consists of : (i) Two auricles (ii) Undivided ventricle (iii) Sinus venosus (iv) Truncus arteriosus (conus + proximal part of aorta) Right auricle receives blood from all the visceral organs (deoxygenated) via precaval and post	Frog Toad Neoceratodus or Dipnoi	Right auricle Ventricle

	ASSESSED INDUSTRALIS	caval. Pulmonary artery carries		ST STANDARD TO STANDARD TO STANDARD
		deoxygenated blood to lungs for oxygenation. This blood returns to left auricle via pulmonary vein (Double circuit circulation) (v) S.A. node in sinus venosus		
		(vi) Truncus arteriosus divided into synangium, pylangium	golf their elgans tra	no nel permitano se Albania.
3.	Reptiles	Heart consists of: (i) Left and right auricle (ii) Incompletely divided ventricle (Ventricle in crocodiles, gavialis, and alligator is completely divided) (iii) Sinus venosus (iv) Conus arteriosus divided into right systemic, left systemic and pulmonary arch. (Double circulation) (v) Foramen panizzae at crossing of right-left systemic arch. (vi) Only SA node in right auricle	Lizards Snakes Turtles	Right auricle Ventricle
4.	Aves	Exhibit double circulation: Heart consists of (i) Left and right auricle (ii) Left and right ventricle (iii) Complete separation of arterial and venous circulation (iv) Only right systemic arch is present (v) Sinus venosus and truncus, arteriosus absent (vi) Two pace maker SA node and AV node (vii) Mitral valve present.	Pigeon	Pulmonary arch Left auricle Left ventricle Right ventricle
5.	Mammals	Same as bird except that mammals have left systemic arch.	Rabbit, man	

Shape and position: Reddish, roughly conical, highly muscular, mesodermal hollow organ of the size of one's fist. Its average weight in males is about 300 gm. and in females about 250 gm. It lies behind the sternum in the mediastinum space of thoracic cavity in between the two lungs. The broader base faces upward and backward. The narrower apex is directed downward, forward and slightly towards left, lying between 5th and 6th ribs and rests on the diaphragm. The heart is about 12 cm (5 inch) long, 9 cm (3.5 inch) wide and 6 cm (2.2 inch) thick.

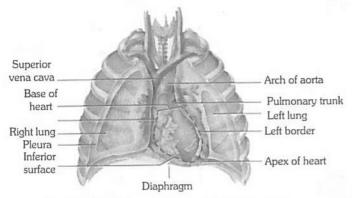

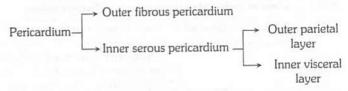

Fig: 5.3-2 Position of heart in our chest cavity

Protective covering: Heart is enclosed in a tough, 2 layered fibroserous sac, the pericardium. The outer layer is non-distensible fibrous pericardium and inner layer is thin serous pericardium which further consists of outer parietal layer (attached to fibrous pericardium) and inner visceral layer (adhered to the heart).

Between the parietal and visceral layers, occurs a narrow potential space, the pericardial cavity which is derived from coelom and is filled with serous pericardial fluid for frictionless movement and protection from shock and mechanical injury.

Histology: The heart wall consists of connective tissue, blood vessels and cardiac muscle fibres in 3 different layers – Epicardium, Myocardium and Endocardium.

(1) **Epicardium**: The outermost epicardium, also called visceral layer of the serous pericardium, is the thin, transparent outer layer of the wall. It is composed of mesothelium and connective tissue. Visceral pericardium, is joined to the myocardium by connective tissue.

UNIVERSAL BOOK DEPOT 1960

- (2) Myocardium: Middle, highly vascular layer, composed of cardiac muscle fibres are joined together by intercalated disc. The connective tissue in myocardium acts as cardiac skeleton. Myocardium is thickest where the endocardium is thinnest.
- (3) Endocardium: Innermost layer lining the cavity of heart and consisting of endothelium of squamous cells resting on thin basement membrane of loose connective tissue.

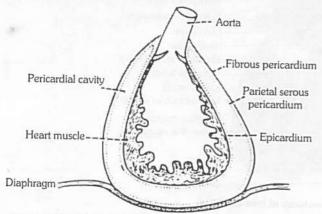

Fig: 5.3-3 Diagram to show the layers of the pericardium

External structure: Human heart is 4-chambered and is divided by septa into two halves – right and left. Each half has one darker, thin walled auricle in the broader upper region and one lighter, thick-walled ventricle in the narrower lower region.

Sinus venosus and conus/truncus/bulbus arteriosus are accessory chambers in the heart of lower vertebrates (fishes and amphibians). In rabbit, sinus venosus is formed in the embryo but later it becomes a part of wall of right auricle.

In frog, sinus venosus spreads upon most of the dorsal side of heart and conus arteriosus lies obliquely upon the ventral surface of right atrium.

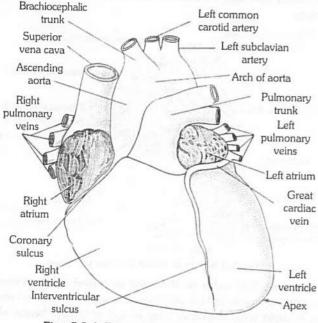

Fig: 5.3-4 External features of human heart

Internal structure

(1) Auricles: Atria are thin walled. They act as reservoirs for blood entering the heart. Right auricle is bigger than left auricle and both are separated by a myomembranous partition called Interatrial or interauricular septum. During embryonic stage, at the place of this septum, there are present septum primum and septum secondum having a gap (aperture) called foramen ovale between them. From the opening of inferior vena cava upto foramen ovale, there is a flap called Eustachian flap which prevents the blood in the foetal heart go to lungs because in foetal life, lungs are not functional purification of blood is done by placenta.

At the time of birth, there is closure of foramen ovale but there remains depression on posterior part of the right surface of interauricular septum in rabbit. In man this depression is present on both the side because of least regenerative power in human being. The depression towards right atrium is called fossa ovalis and depression towards left atrium is called fossa lunata.

The inner surface of auricles is smooth. A network of muscular ridges called musculi pectinati or trabeculi pectinati occurs internally in the region of the auricular appendages and give comb like appearance.

- ☐ PFO (Patent Foramen Ovale) or septal defect: In case there is no closure of foramen ovale, then disease is called PFO. In this condition, there is mixing of blood after birth which gives bluish appearance to the body called as Cyanosis. Such child is called Blue Baby.
- (2) Ventricles: The right and left ventricles are demarcated by an interventricular septum which is obliquely curved towards right, so that the left ventricle is larger than right one. However, the cavity of left ventricle is relatively smaller and nearly circular because the myocardium of left ventricle is 3 times thicker than right ventricle whose cavity is larger and somewhat crescentic.

The walls of the ventricles are internally raised into a number of thick, muscular, column shaped projections called columnae carnae or trabecular carnae; and a few large muscular elevations called papillary muscles or musculli papillares which are 3 in right ventricle and 2 in left ventricle. These muscles act as anchors for chordae tendinae.

Numerous, strong, inelastic thread like tendons are present in the mammalian heart but absent in frog.

- Regurgitation: If there is weakening of papillary muscles or breaking of chordae tendinae, then AV valves revert into auricles. So, blood goes in opposite direction, it is called regurgitation. Sometimes, there is narrowing of valves. So, there remains gap between the valves which causes regurgitation.
- ☐ **Moderator band**: Right ventricle contains a prominent muscular trabeculum called moderator band which extends from the interventricular septum to anterior papillary muscle.

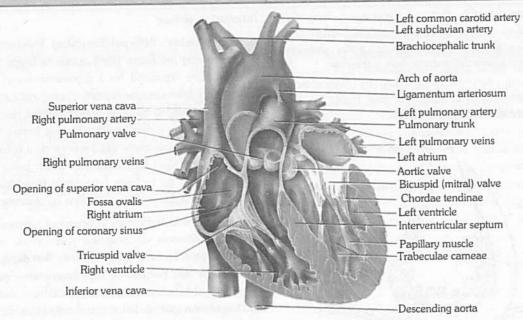

Fig: 5.3-5 Internal anatomy of human heart

Major blood vessels associated with heart: The blood vessels that enter or leave the heart are called Great Blood Vessels.

- (1) **Superior vena cava or precaval:** Brings deoxygenated blood from head and upper parts of the body into the right auricle through an opening which is single in human and cat and two in rabbit as there are 2 precavals right and left in rabbit.
- (2) Inferior vena cava or post caval: Drains deoxygenated blood from middle and lower parts of the body into the right auricle through a single opening which is bordered by a membranous, falciform fold which is a remnant of the foetal valve of Eustachian.
- (3) Coronary sinus: Returns deoxygenated blood from heart wall into right auricle through a single opening.
- (4) Pulmonary vein: Four pulmonary veins, two from each lung, carry oxygenated blood from the lungs and open into the left auricle through four openings. In rabbit, the pulmonary veins open in the left auricle through 2 openings.
- (5) Pulmonary aorta/arch: Arises from upper left corner of right ventricle through a single opening and divides into right and left pulmonary arteries which carry deoxygenated blood to the lungs for oxygenation.
- (6) Systemic aorta: Arises from upper right corner of left ventricle through a single opening and has 3 regions – ascending aorta, arch of aorta and descending aorta. It distributes oxygenated blood to various body parts except lungs.
- Ligamentum arteriosum: During foetal life, because the lungs are non-functional hence blood of pulmonary aorta comes into systemic aorta through a small duct called ductus botalli or ductus arteriosus soon after birth, deposition of elastin fibre blocks this duct, forming a new structure called ligamentum botalli or ligamentum arteriosum.
- □ PDA (Patent Ductus Arteriosus): If the ligamentum arteriosus remains open, the condition is called PDA. In this case, there is mixing of blood which leads to blue baby.

- Valves: Various membranous structure in a hollow organ or passage that temporarily closes in order to permit flow of flood in one direction only.
- (1) Eustachian valve: Present on the opening of inferior vena cava (post caval) in the right auricle in rabbit, whereas in human, the vestige of eustachian valve is present over the opening of post caval vein. It allows the passage of blood in right auricle.
- (2) Haversian valve: Present in human but absent in rabbit. It is present over the opening of precaval vein and allows the passage of blood in right auricle.
- (3) Thebesian or coronary valve: Present over the opening of coronary sinus in right auricle in mammals and allows the passage of blood in right auricle.
- (4) Right A.V. valve or Tricuspid valve: Present between right auricle and right ventricle. It consists of 3 membranous flaps or cusps.

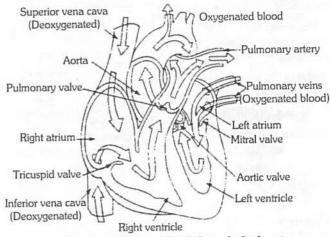

Fig: 5.3-6 Path of blood through the heart

(5) **Left A.V. valve or Bicuspid or Mitral valve:** Present between left auricle and left ventricle. It consists of 2 flaps or cusps. The bicuspid valve resembles mitre or topi of bishop, hence, also called as Mitral valve.

UNIVERSAL BOOK DEPOT 1960

(6) Semilunar valves: At the base of pulmonary arch and systemic aorta, three membranous, pocket-shaped flaps called semilunar valves are present. They allow the passage of blood from ventricles to respective blood vessels, but prevent the return of blood.

Nodal tissue: The nodal tissue consists of the following -

(1) Sinu-auricular or S.A. node: Also called as pacemaker, node of keith and flack, heart of heart, brain of heart, pulsation centre. It is located in the right wall of right atrium below the opening of superior vena cava. This is the place where sinus venosus is incorporated in the wall of right atrium in the embryo. S.A. node is the main tissue of heart and has highest degree of autorhythmicity (generates beating impulse at the rate of 70-80 times/minute) but least conductivity. The rhythmic impulses produced are called as Sinus rhythmia. In frog S.A. node is present in sinus venosus.

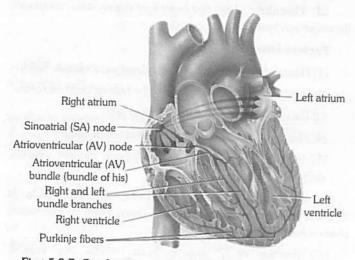

Fig: 5.3-7 Conducting system of rabbit's heart (ventral view)

- (2) Atrio-ventricular node or A.V. node: Also called reserve pacemaker, node of Twara and Aschoff. Discovered by Lewis Kent. It lies in the right atrium near the junction of interauricular and interventricular septum close to the opening of coronary sinus. It is concerned with the conduction of cardiac impulses generated by S.A. node, but it can also generate the impulse at the rate of 40-60/minute. These impulses produced are rhythmic and called nodal rhythmia. In frog, A.V. node is absent.
- (3) **Bundle of His or A.V. bundle**: Discovered by His. It arises from A.V. node, descends in the interventricular septum and bifurcates into two branches innervating the wall of right and left ventricle respectively. The myocardium of atria and ventricles are discontinuous and this bundle is the only muscular connection between the two. It is concerned with the conduction of impulse from atria to the tip of ventricle but can also generate impulse at the rate of 35-40/minute. The impulses produced are non-rhythmic.
- (4) Purkinje fibres: Numerous, modified muscle fibres which act as sympathetic nerve fibres. They arise from branches of bundle of His and provide impulse to myocardium of ventricles. They can also generate non-rhythmic impulse at a rate of 30-35/minute.

Working of nodal tissue: S.A. node spontaneously initiates a wave of contraction which is conducted along the tracts of special muscle fibres called internal pathways over both the auricles at a rate of 1m/sec. The impulse generated travels first in the right atrium than in left atrium. So, right atrium contracts first but the contraction ends simultaneously in both atria. As the musculatures of atria and ventricles are discontinuous and are separated by a septum of fibrous connective tissue, called annular pad in mammals, the wave of contraction is received by A.V. node from myocardium of atria and is provided to bundle of His. The impulses reach the A.V. node about 0.03 seconds after their origin from S.A. node. The A.V. node generates a fresh wave of contraction which passes over both the ventricles along the bundle of His and its ramifications at the rate of 1.5 to 4 m/sec. The Purkinje fibres bring about the contraction of ventricles from the apex of heart which passes quickly towards the origin of pulmonary and systemic arches forcing blood into them.

S.A. node not only acts as pacemaker but also establishes the basic rhythm at which the heart beats. In case of degeneration of S.A. node, A.V. node can generate impulse but it will lead to abnormal beating. The failure of atrial impulse to pass into ventricles for a few seconds to few hours is called ventricular escape or stokes-adams syndrome leading to delayed pick up of heart beat. In such conditions, artificial pacemaker (Lithium Battery) is placed underneath the patient's chest.

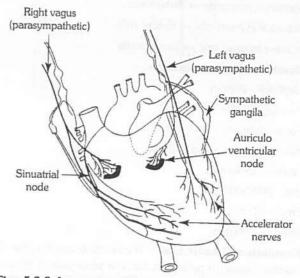

Fig: 5.3-8 Innervation of human heart by autonomic nerves

☐ Ectopic pacemaker: If any cardiac muscle other than the conducting tissue (nodes) generates impulse, then extra beats are heard. Such muscles are called Ectopic pacemaker.

In mammals, conducting system of the heart has S.A. node, A.V node and complicated system of conducting fibres. But in frog, it has only S.A. node and system of conducting fibres is simple.

Heart beat : The spontaneous and rhythmic contraction and relaxation of the heart to pump out and receive blood to and from the body is called Heart beat. Depending upon the nature of control of the heart beat, hearts are of 2 types – Neurogenic and Myogenic or autorhythmic.

Table: 5.3-4 Differences between Neurogenic heart and Myogenic heart

S. No.	Neurogenic heart	Myogenic heart The heart beat is initiated by a patch of modified heart muscle.	
1.	The heart beat is initiated by a ganglion situated near the heart.		
2.	The impulse of contraction originates from nervous system.	The impulse of contraction originates itself in the heart.	
3.	The heart normally stops beating immediately after removal from the body. Therefore, heart transplantation is not possible.	The heart removed from the body continues to beat for some time. Therefore, heart transplantation is possible.	
4.	Examples: Hearts of some annelids and most arthropods.	Examples: Hearts of molluscs and vertebrates.	

Origin and conduction of heart beat: Initiation of heart beat is under special bundles of cardiac muscles called nodal tissue or autorhythmic cells. They act as pace maker so setting the rhythm for the entire heart and they form conducting system.

Heart rate : Heart beat/minute or number of cardiac cycles/minute. Females have higher heart rate than males.

Normal heart beat rate → Rhythmia

Abnormal heart rate → Arrhythmia

Decrease in heart rate → Bradycardia

Increase in heart rate → Tachycardia

Heart rate in some animals

Elephant - 29/min.

Human - 70-80/min.

Foetus (human) - 140-150 / min.

New born baby - 115-130/min.

Horse - 35-40/min.

Rat - 300-500/min.

Frog - 64/min.

Rabbit - 200/min.

Regulation of heart beat : The centre controlling the heart rate (cardiac centre) is present in medulla oblongata of brain and possess chemoreceptors sensitive for CO_2 , O_2 and also for blood pressure. This centre is under the influence of hypothalamus which is the controller of autonomic activities.

(1) Nervous control: Brain receives two sets of nerve fibres: Sympathetic and para sympathetic or vagal.

When there is increase in blood CO_2 , the sympathetic nerve fibres stimulate S.A. node by producing sympathin (adrenaline + noradrenaline). This compound induces impulse generation by inducing entry of Ca^{2+} into cardiac muscles. So, heart beat and force of contraction increase (Tachycardia). After action, sympathin is destroyed by sympathenase, COMT (catechol orthomethyl transferase) and MAO (Mono Amino Oxidase).

When there is increase in blood O_2 , the parasympathetic or vagal (10^{th} cranial) nerve inhibits S.A. node by producing acetylcholine. This compound increases contraction time and hence, heart beat is decreased (Bradycardia). After action, acetyl choline is destroyed by enzyme acetyl choline esterase (AchE). This chemical regulation of heart beat on behalf of nerves was discovered by Otto Loewi.

- ☐ Vagus escape: Stimulation of vagus nerve decreases the heart rate but its continuous stimulation shows no further decrease. This phenomenon is called Vagus escape.
- (2) Hormonal control: Hormones from adrenal medulla adrenaline and nor adrenaline accelerate the heart beat, the latter under normal conditions and the former at the time of emergency. Thyroxine hormone also increases the heart beat by increasing energy production.
- ☐ **Pounding:** Very fast heart beat during some conditions like anger and love.

Factors affecting heart rate

- (1) Heart rate increases with increase in basal metabolic rate (BMR).
- (2) Heart rate increases as the size of the animals body decreases.
- (3) Decrease in pH also increases heart rate.
- (4) Heart rate increases with increase in temperature.
- (5) Increase in Na^+ ions in blood or in cardiac muscles, decrease heart rate.
- (6) Increase in Ca^{2+} ions in blood increases heart beat but if they are injected in cardiac muscles, heart stops in contracted phase which is called Systolic Arrest.
- (7) Injection of K^+ ions in heart muscles stop impulse generation. So, heart stops in diastolic or Relax phase.
 - (8) H^+ ions reduces force of contraction of heart.
- (9) Increased inspiration, muscular exercise, low oxygen tension, injection of adrenaline, thyroxine, sympathin – all increase heart rate.
- (10) Increased expiration, during sleep, injection of acetylcholine decrease heart rate.
 - (11) Stenosis Narrowing of valve is called stenosis.
 - (12) Alkalosis Decreases heart rate.
 - (13) Anoxia (Absence of O_2 in tissue) Increases heart rates.
 - (14) CO2 in more amount, decreases heart rate.
 - (15) CO2 in moderate amount, increases heart rate.
 - (16) Epinephrine and nor-epinephrine increase heart rates.
 - (17) Thyroid hormone increases heart rate.

Cardiac cycle

The sequence of event which takes place from the beginning of one heart beat to the beginning of the next is called as cardiac cycle. Following events are repeated in a cyclic manner during each heart beat.

- (1) Auricular systole: The atria contract due to wave of contraction stimulated by S.A. node contraction of auricles drives most of their blood into respective ventricles as the A.V. valves are open. There is no backflow of blood into the large veins as the contraction begins at the upper end and passes towards ventricles and moreover, the valves present at the opening of these veins close. Also, blood is already present in large veins which offers resistance to the blood that may return from the atria. At the end of a atrial systole, there starts the relaxation of auricles (auricular diastole) and contraction of ventricles (ventricular systole) simultaneously. Atrial systole takes 0.1 second while atrial diastole is of about 0.7 seconds.
- (2) Ventricular systole: The ventricles begin to contract due to a wave of contraction stimulated by A.V. node. Due to ventricular systole, the pressure of blood in ventricles immediately rises above that in the auricles. With this pressure, the bicuspid and tricuspid valves close rapidly to prevent the backflow of blood. This closure of A.V. valves at the start of ventricular systole produces first heart sound called "Lubb" or Systolic sound. The semilunar valves are also close at this time. When the pressure of blood in the ventricles exceeds that in the great arteries, the semilunar valves open and blood enters into the great arteries. This marks the end of ventricular systole which takes about 0.3 seconds. Now the ventricles start relaxing (ventricular diastole which lasts for about 0.5 sec.)
- (3) **Joint diastole**: The ventricles and auricles are in the diastolic phase simultaneously. As the ventricular diastole progresses, the pressure in the ventricles falls below that in the great arteries. So, to prevent backflow of blood from great arteries into ventricles, the semilunar valves close rapidly. This rapid closure of semilunar valves at the beginning of ventricular diastole produces second heart sound "Dup" or diastolic sound.

Heart Sounds

Heart sounds can be listened with the help of an instrument called STETHOSCOPE. It was invented by Laennae.

There are four heart sounds, designated as S_1 , S_2 , S_3 and S_4 .

First Heart Sound : S_1 is known as "LUBB" a long and louder sound produced by the closure of atrioventricular valves (tricuspid and bicuspid) at the beginning of ventricular system.

Second Heart Sound : S_2 is known as "DUP" a short and sharper sound created by the closure of semilunar valves towards the end of ventricular systole.

Third And Fourth Heart Sounds: S_3 and S_4 are usually very faint sounds and hence may not be audible. These sounds are associated with rapid ventricular filling (S_3) and atrial systole (S_4) .

Heart sounds provides valuable information about working of valves. Defective or damaged heart valves lead to the backflow of blood either from ventricles to auricles or from aorta to ventricles. Such defects are detectable as abnormal hissing sound called 'MURMER' Defective valves may be replaced or repaired surgically.

The instrument used to magnify and record the heart sound is called PHONOCARDIOGRAM.

During joint diastole, blood from great veins and coronary sinus flows into the atria and some blood also passes from auricles into the respective relaxing ventricles due to less pressure in ventricles. This phase takes only 0.4 seconds and is also called as blood receiving period of heart. Thus a cardiac cycle is completed in 0.8 seconds.

Cardiac output: Volume of blood pumped from heart (left ventricle) into the systemic aorta in one minute is called cardiac output. It is also called minute volume. It is calculated as the product of stroke volume (amount of blood pumped by left ventricle each time it contracts) and rate of heart beat.

- i.e. Cardiac output = Stroke volume × Rate of heart beat
- = $70 \text{ ml} \times 75 \text{ times/minute}$ = 5250 ml/minute or 5.25 litres/min.

Total amount of blood in human body is about 5 litres (7% of body weight). During mild exercise, the cardiac output rises to about 11 litres. During intense exercise, cardiac out put rises to 19.5 litres/min., and heart beat may rise to 130 beat/minute. Cardiac output is directly proportional to the size of the organism, metabolic rate etc. but is inversely proportional to age.

- Fractions of cardiac output: Amount of pure blood going to an organ per minute is called as fraction of the organ.
 - (i) Cardiac fraction 200 ml/min.
- (ii) Hepatic fraction (maximum) 1500 ml/min. (28% of blood as liver is the busiest organ of body and has maximum power of regeneration).
 - (iii) Renal fraction 1300 ml/min (25% of blood)'
 - (iv) Myofraction 600-900 ml/min.
 - (v) Cephalic organs (brain) 700-800 ml/min.
 - (vi) Remaining organs Remaining blood.
- (2) Cardiac index: Cardiac output per square metre of body surface area per minute. As area of normal young adult is 1.7 metre square, so, cardiac index is 3 litres/min/square metre.
- (3) Cardiac reserve: Maximum amount of blood that can be pumped by left ventricle under the conditions of maximum needs. In this condition, heart beat can go upto 250 and stroke volume can go upto 100 ml per systole. Cardiac reserve is 25-30 litres which is about 5-6 times of cardiac output.
- (4) End diastolic volume (EDV): Amount of blood present in left ventricle at the end of diastole. It is the maximum volume of the cavity of left ventricle and is equal to 120-130 ml.
- (5) End systolic volume (ESV): Amount of blood present in left ventricle at the end of systole. It is the least volume of the cavity of left ventricle and is equal to 50-60 ml.
- (6) **Stroke volume**: (70 ml) is equal to the difference between the end diastolic volume and end systolic volume.

$$SV = EDV - ESV$$

(7) Venous return: Amount of impure blood returning to right atrium per minute is called venous return and is equal to 5.25 litres.

Electrocardiogram (ECG)

A graphic record of electrical events occuring during a cardiac cycle is called Electrocardiogram. It was invented by Einthoven. The instrument used for recording the heart's electrical variations is called Electrocardiograph in which the potential differences of heart muscles are recorded by a galvanometer. In ECG, there are 2 types of waves:

- (1) Depolarisation waves: They represent the generation of the potential difference. These waves appear only when both electrodes of galvanometer are in different fields. When both the electrodes are in same field, there is no deflection and wave drops down to base line.
- (2) **Repolarisation waves :** They appear when depolarisation is over and the muscle fibre is returning to its original polarity. When both electrodes are in same polarity (means 100% repolarisation and 100% depolarisation), there is no deflection.

A normal ECG has 5 deflection waves -P, Q, R, S and T. Out of them -P, R and T waves are above the base line and are called positive waves. The Q and S waves are below base line and are called negative waves. The part of the base line between any 2 deflections is called Interval.

 ${\it P}$ wave: Indicates impulse of contraction generated by S.A. node and its spread in atria causing atrial depolarisation. The interval ${\it PQ}$ represents atrial contraction and takes 0.1 second.

QRS complex: Indicates spread of impulse of contraction from A.V node to the wall of ventricles through bundle of His and purkinje fibres causing ventricular depolarisation. This complex also represents repolarization of S.A. node.

The RS of QRS wave and ST interval show ventricular contraction (0.3 seconds). QRS is related to ventricular systole.

T wave: Indicates repolarisation during ventricular relaxation.

Any abnormality in the working of heart alters the wave pattern of ECG. Thus, ECG is of great diagnostic value in cardiac diseases. ECG also indicates the rate of heart beat

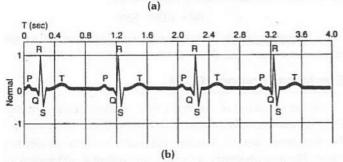

Fig: 5.3-9 (a)Normal ECG deflections, Depolarisation and repolarisation (b) Normal electrocardiogram

Blood vessels

The study of blood vessels is called Angiology. The blood vessels are of following types:

- (1) **Arteries**: Thick walled, carrying oxygenated blood (deoxygenated in pulmonary artery) from heart to various parts of body. These blood vessels are grouped as Aorta which branches to form arteries which further divides into thinner branches called arterioles inside the organ. Average diameter of arteriole is 120 μm . the arterioles further divide into smaller vessels called meta-arterioles (70 μm) which divide into capillaries. At the beginning of capillary, the arterioles posses circular muscles called precapillary sphincter which regulates flow of blood into the capillaries which is called vasomotion. Smooth muscles of arteries are innervated by sympathetic fibers, their stimulation control vasoconstriction and vasodilation. Smooth muscles of arteries and arterioles also limit bleeding from wounds by producing vascular spasm during cut. Arteries are of two types.
 - (i) Conducting or elastic arteries
 - (ii) Distributing or muscular arteries.

Elastic or conducting arteries receive blood from heart and do not provide it to any organ rather they provide blood to other atreries and are pressure reservoirs of blood.

Muscleless end of meta-arteriole is called thoroughfare channel or preferential channel.

The largest artery is dorsal / abdominal aorta (systemic aorta).

- Anastomosis: If more than one arteries are supplying to one organ then branches of these arteries unite to form a network called Anastomosis. It provides many collateral or alternate pathways of blood supply. So, if there is blocking of any artery, it will not lead to necrosis.
- (2) **Capillaries**: Smallest blood vessels, discovered by Marcello Malpighi. The wall is formed of single layer of endothelium resting on a basement membrane. Diameter of capillary is about 8μ . These are also called as exchange vessels as they are the site of exchange of material between blood and tissue because of least barrier in them. The capillaries can be grouped into two categories:
- (i) Arteriolar capillary: Which supplies nutrition, respiratory gases etc. to the body cells.
- (ii) Veinular capillaries: Which collect the metabolic wastes from the body cells.

Capillaries possess about 7% of total body blood and are present near almost all cells of body in the intercellular spaces. The tissues which are devoid of intercellular spaces are also devoid of capillary. They are called avascular tissues.

Capillaries are surrounded by cells of connective tissue called pericapillary cells. Some of these cells are contractile and phagocytic in nature and are called Rouget cells or pericytes.

Continuous capillaries are without fenestra/aperture, hence are less permeable. These are present in organs such as lungs, muscles, connective tissues and brain tissues.

UNIVERSAL BOOK DEPOT 1960

Fenestrated capillaries possess apertures/fenestra and are found in those organs where there is maximum need of permeability such as endocrine glands, intestinal villi, cavities of brain, kidney, ciliary body of eye.

Sinusoids are irregularly dilated capillaries found in organs where there is decrease in flow rate such as liver, spleen, bone marrow, parathyroid, pituitary gland. In liver, sinusoids are branches of venules and open into venules while in other organs, they originate from arteriole and unite to form venules.

(3) **Veins**: These are thin walled, carrying deoxygenated blood (oxygenated in pulmonary vein) from tissues to the heart. Venules, smallest branches, unite to form veins which in turn unite to form vena cava. The largest vein is inferior vena cava/post caval. Varicose veins are stout, blood filled painful veins specially of the limbs due to defective watch pocket valves.

Histology of arteries and veins

- (1) Tunica externa or tunica adventitia: Outermost, fibrous, made up of collagen rich connective tissue and less elastin fibres. The collagen fibres give strength to the blood vessels and prevent their overdilation.
- (2) Tunica media: Middle, thickest, made up of smooth involuntary muscle fibres and elastin fibres. This layer is very much variable because number of elastin fibres and muscle fibres depend upon the position of blood vessels from the heart.
- (3) **Tunica interna or tunica intima :** Innermost, thinnest, made up of inner, single layer of simple squamous epithelial cells called endothelium resting on a basement membrane and outer layer of elastic (yellow fibrous) connective tissue. The hollow space in the blood vessel is called lumen.

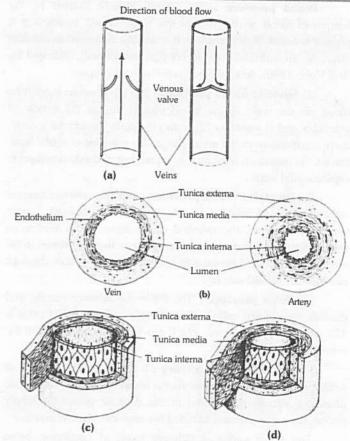

Fig: 5.3-10 (a) Venous valves, (b-d) Histology of the blood vessels

Table: 5.3-5 Differences between arteries and veins

S.No.	Characters	Arteries	Veins
(1)	Wall	Thick, more elastic, non collapsible.	Thin, less elastic, collapsible.
(2)	Tunica externa	Less developed, so less strong.	More developed, so more strong.
(3)	Tunica media	More muscular and has many elastic fibres.	Less muscular and only a few elastic fibres.
(4)	Tunica interna	Endothelial cells more elongated. Elastic membrane more developed.	Endothelial cells less flat. Elastic membrane less developed.
(5)	Lumen	Narrow	Wider
(6)	Position	Deep seated except wrist, neck etc.	Superficial
(7)	Valves	Without valves.	With valves to prevent back flow.
(8)	Direction of blood flow	From heart to body organs	From body organs to heart
(9)	Nature of blood	Oxygenated except pulmonary artery.	Deoxygenated except pulmonary vein
(10)	Blood pressure	More, generally 120/80 mm of Hg.	Less, generally 0 mm of Hg.
(11)	Speed of blood	Fast	Slow
(12)	After death	Becomes empty	Contain blood
(13)	Amount of blood	15% at any given time.	64% at any given time
(14)	Colour	Pink	Dark red
(15)	Distensibility	Less	More
(16)	Average Blood pressure	More	Less
(17)	Elastic-lamina	Present	Absent

Blood pressure: The lateral pressure exerted by the column of blood on the wall of the blood vessels in which it is present is called blood pressure. It is usually measured in brachial artery by an instrument called sphygmomanometer (invented by Riva-Rocci 1896). Arterial blood pressure is of 2 types:

- (1) **Systolic blood pressure**: It is the pressure exerted by blood on the walls of the blood vessels due to the systole of ventricles and is equal to 120 mm Hg during ventricular systole, there is expansion in the artery due to the uncoiling of elastic layer. Hence, the pressure is maximum in arteries but gradually decreases in capillaries and veins.
- (2) **Diastolic blood pressure**: It is the pressure exerted on walls of blood vessels when the ventricles are relaxed. During ventricular diastole, the uncoiled elastic layer recoils leading to normalization of artery. Hence, blood pressure drops down to 80 mm Hg. Thus, blood pressure in normal person is systolic/diastolic pressure i.e. 120/80 mm Hg.
- (3) **Pulse pressure :** The difference between systolic and diastolic pressures is called pulse pressure and its normal value is $120-80 \ mm \ Hg = 40 \ mm \ Hg$. It provides information about the condition of arteries.
- (4) Mean arterial pressure: It is the average pressure of systolic and diastolic pressures. As the blood remains in the systolic phase for shorter period and in the diastolic phase for longer period, the mean pressure of blood lies near the diastolic pressure.

This value varies at different levels of circulation being maximum (100 mm Hg) in the aorta and minimum (0 mm Hg) in the venae cavae under normal conditions.

Pulse: It is the pressure wave of distension and recoiling felt in the radial artery due to the contraction of left ventricle which force about 70-90 *ml* of blood in each cardiac cycle to aorta. This pressure wave of contraction travels down to the wall of the arteries and is called the pulse.

The pulse is measured in the radial artery in the wrist but can be felt in the temporal artery over the temporal bone or the dorsal pedis artery at the back of ankle. The pulse normally travels at the rate of $5-8\ m/second$.

Since each heart beat generates one pulse in the arteries so the pulse rate per minute indicates the rate of heart beat. So the normal pulse rate in a normal adult person is 72/minute.

The normal ratio of systolic pressure to diastolic pressure to pulse pressure is about 3:2:1.

Factors affecting blood pressure

- (1) Age: With the advancing age, BP increases after the age of 60 years, it is calculated as 100 + age of the person.
- (2) Cardiac output: BP increases with the increase in cardiac output.
- (3) **Elasticity of blood vessels**: BP is inversely related to the elasticity of the blood vessels.
- (4) **Total peripheral resistance :** Constriction of the blood vessels increases BP whereas dilatation of the blood vessels decreases BP.

Hypotension : Low blood pressure with systolic below 110 mm Hg and diastolic below 70 mm Hg. It is caused by low metabolic rate, starvation, anaemia, chronic vasodilation of arterioles, lower pumping activity of heart, loss of blood in haemorrhage, valvular defects, nervous disorders and Addison's disease. It may cause fainting. Also due to lowering of oxytocin, Acetylcholine. ANP (Atrial Natriuretic Peptide) Low Ca⁺⁺, Low BMR.

Hypertension: Persistent high blood pressure with systolic more than 140 mm Hg and diastolic more than 90 mm Hg. It is caused by decrease in extensibility of the artery due to atherosclerosis and arteriosclerosis. Sclerosis means hardening and narrowing of blood vessels which may be due to the deposition of cholesterol or calcium or lipid or any other compound in the wall of the arteries and arterioles.

In atherosclerosis deposition is mainly in tunica interna of the blood vessels which prevents their dilation. The atherosclerosis is, infact, the beginning of thickening and hardening of blood vessels but later, the deposition of cholesterol and other compounds takes places in both tunica media and tunica interna leading to arteriosclerosis.

Hypertension caused by hormones (epinephrine, aldosterone, renin) is called secondary hypertension, other forms of hypertension are known as primary or essential hypertension.

Blood circulation in human

The physiology of blood circulation was first described by Sir William Harvey in 1628. The blood circulation in our body is divisible into 3 circuits – $\,$

- Coronary circulation: It involves blood supply to the heart wall and also drainage of the heart wall.
- (i) **Coronary arteries**: One pair, arising from the aortic arch just above the semilunar valves. They break up into capillaries to supply oxygenated blood to the heart wall.
- (ii) Coronary veins: Numerous, collecting deoxygenated blood from the heart wall and drains it into right auricle through coronary sinus which is formed by joining of most of the coronary veins. But some very fine coronary veins, called venae cordis minimae open directly in the right auricle by small sized openings called foramina of Thebesius.
- (2) **Pulmonary circulation**: It includes circulation between heart and lungs. The right ventricle pumps deoxygenated blood into a single, thick vessel called pulmonary aorta which ascends upward and outside heart gets divided into longer, right and shorter, left pulmonary arteries running to the respective lungs where oxygenation of blood takes place. The oxygenated blood from lungs is returned to the left auricle by four pulmonary veins. Left auricle pumps this blood into the left ventricle.
- (3) **Systemic circulation:** In this, circulation of blood occurs between heart and body organs. The left ventricle pumps the oxygenated blood into systemic arch which supplies it to the body organs other than lungs through a number of arteries. The deoxygenated blood from these organs is returned to the right auricle through two large veins (precaval and post caval). Right auricle pumps this blood into the right ventricle. Thus, the sytemic circulation involves two circuits –

Arterial system

It involves aorta, arteries, arterioles and meta-arterioles. It supplies oxygenated blood to all parts of the body except lungs.

The left ventricle of the heart pumps the oxygenated blood into a single, question marked shaped, long vessel called left carotid-systemic aorta. It is the largest blood vessel of the body.

After ascending from the heart, the systemic aorta turns and descends down to the level of lower border of fourth lumbar vertebra. At its distal extremity, it bifurcates into right and left common iliac arteries. The sytemic aorta has following parts —

 Ascending aorta: It gives off left and right coronary arteries.

Brachiocephalic (innominate): Unpaired, largest branch of the aorta divides into right subclavian towards right side and right common carotid towards left side. Right subclavian gives off vertebral artery (supplies to head and part of right shoulder) and then enters into right arm, now called axillary artery or brachial artery, which divides into ulnar and radial arteries in the region of elbow. The right common carotid, enters into head and divides into external and internal carotids which supply the right parts of head by their branches.

Left common carotid: Unpaired artery, enters into head and divides into left external and internal carotids which supply the left part of the head by their tributaries. The external carotids of both sides provide blood to thyroid gland, tongue, throat, face, ear, scalp. The internal carotids of both sides supply to brain, eye, inner part of nose and forehead. These internal carotids go upward and enter skull through foramen magnum and unite at the base of brain along with the vertebral arteries of both sides. So, there is formation of a ring shaped artery called as "Circle of willis". From this circle, many branches or arteries arise which go to different parts of brain.

In frog, the internal carotid has at its base, carotid labyrinth (spongy mass of non-contractile fibro-elastic tissue) which acts as a sensory organ to detect blood pressure in artery.

Left subclavian artery: Unpaired artery, it gives off a left vertebral artery (supplies to head and part of left shoulder) and then enters into left arm, now called left axillary artery or left brachial artery which divides into ulnar and radial arteries in the region of elbow.

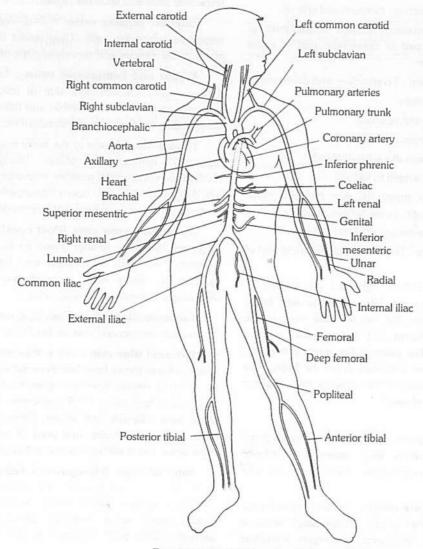

Fig: 5.3-11 Arterial system in human body

(2) Descending aorta: The aorta turns towards the back of heart and finally converts into dorsal aorta. The descending dorsal aorta is called thoracic aorta in thoracic region and abdominal aorta in abdominal region.

From thoracic segment of aorta: Several pairs of small arteries arise in this region to supply various parts such as pericardium (pericardial artery); lungs and bronchi (bronchial artery); oesophagus (oesophageal artery); mediastinal organs and thymus (mediastinal artery); intercostal muscles and mammary glands (intercostals and subcostal arteries); upper surface of diaphragm (superior phrenic artery).

From abdominal region of aorta: In the abdominal region, abdominal aorta gives off several pairs of arteries. Some of the major ones are as follows –

Inferior phrenic artery: Right and left to supply the lower surface of the diaphragm.

Coeliac artery: Unpaired, divides into three branches

- (i) Left gastric artery: To stomach.
- (ii) Common hepatic artery: To pylorus, pancreas, gall bladder, liver, cystic duct, hepatic ducts etc.
 - (iii) Splenic artery: To pancreas, stomach and spleen.

Superior mesenteric: Unpaired, supplies various parts of small intestine (except superior part of duodenum part of colon and caecum). Its sub branches are

- (i) Pancreo duodenal artery: To pancreas and duodenum.
- (ii) Jejunal artery: To jejunum.
- (iii) Iliac artery: To ileum and jejunum.
- (iv) Iliocolic artery: To ileum and colon.

Supra renal artery: Supplies the adrenal glands.

Renal arteries: One pair, supply to kidney.

Lumbar arteries : 4 pairs, supply the skin, muscles, joints, vertebrae, meninges, spinal cord etc. in the lumbar region.

Sacral artery: Supplies the tissues of sacral region.

Inferior mesenteric artery: Unpaired, supplies most part of colon, rectum and anal canal.

Common iliac arteries: Two, right and left, formed by bifurcation of aorta at its lower end. Each common iliac artery divides into external and internal iliac arteries. The internal iliac (hypogastric) artery supplies viscera and wall of pelvic region, perineum and gluteal regions. The external iliac artery enters into the leg now called femoral artery continues down the thigh, now called popliteal artery which bifurcates into anterior and posterior tibial arteries, at about the level of knee.

Venous system

It originates in tissues by union of capillaries and ends in the atrium of heart. It includes two major veins – superior and inferior vena cava which drain the deoxygenated blood into the right atrium.

(1) **Superior vena cava (pre caval) :** Single, formed by the union of right and left brachiocephalic (innominate) veins. It collects blood from head, neck, arms and chest region. It involves the following veins –

Brachiocephalic veins: Two, each is formed by the union of an outer subclavian vein and medial internal jugular vein. Each vein also receives blood from different thoracic parts of its sides through three main veins.

- (i) Internal thoracic vein: From some muscles and mammary glands.
 - (ii) Inferior thyroid vein: From thyroid gland.
- (iii) Left superior intercostal vein: From upper part of thorax.

Internal jugular vein : Two, right and left. Each one is formed by the union of numerous sinuses and veins of the cranial cavity, superior part of the face and some part of neck and collects blood from these regions.

Subclavian veins: Two, right and left, formed in the shoulder region by union of cephalic and axillary veins of respective sides.

- (i) **Axillary veins:** Two, right and left, present in the respective arms and collect blood from these regions.
- (ii) Cephalic veins: Two, right and left, collect blood from respective arms and shoulder region.

External jugular veins : Two, right and left, open into respective subclavian vein. They collect the blood from parotid gland, facial muscles and superficial parts of cranium.

Azygos and hemiazygos veins: Azygos vein originates in lumbar region towards right side of mediastinum and ascends upwards small veins from lumbar and thoracic parts of backbone, oesophagus, mediastinum, pericardium etc. empty into it.

Towards the left side of the body originates hemiazygos and accessory hemiazygos collects blood from oesophagus, mediastinum, intercostal muscles, mammary glands etc. and drains into Azygos which in turn opens into superior vena cava. Accessory hemiazygos drains blood into left innominate vein.

(2) Inferior vena cava (Post caval): It is the largest vein, originated in inferior lumbar region by the union of right and left common iliac veins and opens into right atrium by separate opening. It collects blood from all body structures below the diaphragm. It involves following veins —

Common iliac veins: Two, right and left. Each one is formed by union of external and internal iliac veins.

External iliac vein: This is the continuation of femoral vein which collects blood from leg. Femoral vein in turn is formed by the union of anterior tibial vein, posterior tibial vein, popliteal vein, large saphenous vein, small saphenous vein, etc. which collect blood from different parts of leg. External iliac vein also collects blood from pubic region and parts of pelvis through number of small veins. Great saphenous vein is the longest vein of the body.

Internal iliac (Hypogastric) veins: Two, right and left. Each one is formed by union of number of small veins, which collect blood from pelvis, pelvic viscera, pelvic girdle, sacrum, rectum, ureter, urinary bladder, uterus, vagina, prostate glands, seminal vesicle, penis, scrotum etc. (i.e. number of reproductive organs).

UNIVERSAL BOOK DEPOT 1960

Lumbar veins : Four pairs, which collect blood from muscles, skin and vertebrae of lumbar region and drains it into inferior vena cava.

Genital veins: In man, right testicular vein collects blood from male organs and inguinal regions and drains it into inferior vena cava. Left testicular vein drains the blood into left renal vein. In woman, the right ovarian vein drain blood from ovaries, uterus etc. and empties into inferior vena cava. The left ovarian vein opens into left renal vein.

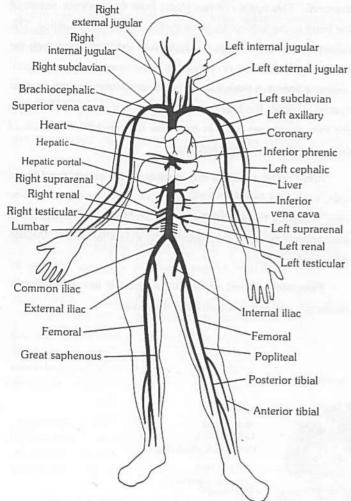

Fig: 5.3-12 Venous system in male human being

Renal veins: Two, right and left collects blood from respective kidneys and opens into inferior vena cava. The left renal vein is about three times longer than the right one.

Suprarenal vein : Two, right and left, collects blood from adrenal glands. Right one opens into inferior vena cava whereas left one opens into left renal vein.

Inferior phrenic veins: These veins drain the blood from lower surface of diaphragm. The right one ends in post caval. The left one is often doubled with its one branch ending in left renal or suprarenal vein and the other in post caval.

Hepatic veins: They drain blood from liver into the post caval. Urea is maximum in hepatic vein while it is minimum in renal vein.

Portal system

It is a part of venous circulation which is present between two groups of capillaries *i.e.* starts in capillaries and ends in capillaries. The vein which drains blood into organs other than heart is called portal vein.

Types of portal system: It is of following types:

(1) Hypothalamo-hypophyseal portal system: Present in higher vertebrates (amphibia, reptiles, birds and mammals). Blood from hypothalamus is collected by hypophyseal portal vein which ends in anterior lobe of pituitary gland. The superior hypophyseal artery which bring blood into circle of willis bifurcate outside the lobe; one branch supplies the lobe itself, but the other one supplies the hypothalamus. The vein that drain the blood from hypothalamus then runs into pars distalis and divide into capillaries. Thus this is a portal vein called hypothalamo-hypophyseal portal vein.

Function : This portal system enables the releasing factors and inhibiting factors from hypothalamus to reach upto anterior pituitary.

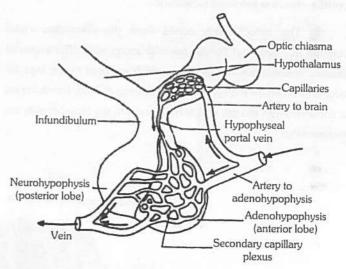

Fig: 5.3-13 Human hypophyseal portal system

- (2) Hepatic portal system: Found in all chordates. In mammals, there is a single vein called hepatic portal vein, formed by the union of six main veins, which drain venous blood from different parts of alimentary canal (digestive system) into the liver. These veins are:
- (i) **Posterior or Inferior mesenteric vein :** Collect blood from rectal wall and anal region. This vein possess maximum diluted blood. Posterior mesenteric made up of by joining of 4 small veins that is rectal vein, sigmoid vein, left colonic vein and it opens into the splenic vein.
- (ii) Anterior or Superior mesenteric vein: Collect blood from wall of colon, caecum and small intestine. This vein possesses largest concentration of nutrients (glucose, amino-acid and vitamins). This vein formed by the joining of right colonic vein, ileocolic vein and appendicular vein.

- (iii) Splenic vein: Collect blood from spleen and pancreas, splenic vein possess free haemoglobin in large amount.
 - (iv) Right gastric vein: Receives blood from stomach.
- (v) Left gastric vein : Receives blood from stomach and pancreas.
 - (vi) Cystic vein: Receives blood from gall bladder.

Posterior mesenteric vein open into splenic vein and splenic, anterior mesenteric, right gastric fused to form hepatic portal vein, which leads blood into the liver.

In amphibians (example – frog), hepatic portal system is formed of single hepatic portal vein and single anterior abdominal vein. The latter collects blood from leg region and drains it into the left lobe of liver.

Significance of hepatic portal system : The hepatic portal system has following significance.

(a) The blood which comes from the alimentary canal contains digested food like glucose and amino acids. The excess of glucose is converted into glycogen which is stored in the liver for later use. When an individual feels deficiency of food, the glycogen is converted into glucose and is transferred to the blood stream via hepatic veins.

- (b) Harmful nitrogenous waste like ammonia is converted into urea which is later removed by kidneys. Thus the blood is detoxified (purified) of harmful nitrogenous waste.
- (c) Liver produces blood proteins which are put into blood circulation.
- (3) Renal portal system: It is well developed in fishes and amphibians, it is reduced in reptiles and birds and is absent in mammals. This system carries blood from the posterior region of the body to the kidneys by renal portal veins, hence its name. The kidneys remove the waste products from the blood and then the blood is passed to the post caval by renal veins. Why renal portal system is absent in mammals? The mammals have no renal portal system because, the heart of mammals is four chambered. Due to the four chambered heart in mammals there is total separation of oxygenated and deoxygenated blood.

Renal portal system in frog consists of one pair of renal portal vein, each one formed by the union of femoral vein and sciatic vein. It collects blood from leg region and drains it into kidney. It also collects blood from dorsal part of lumbar region through dorsolumbar vein.

Function : Renal portal system helps in blood filtration by draining it into kidney which filters the blood

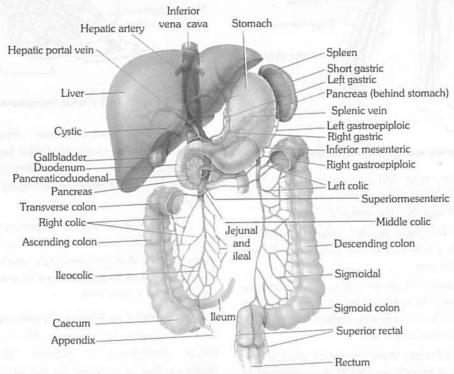

Fig: 5.3-14 Human hepatic portal system

Lymphatic system

It is a part of greater circulation which begins in the tissue fluid with lymphatic capillaries which are always terminally closed. This system terminates into venous system near heart. The main components of this system are:

(1) **Lymph**: Lymph can be defined as blood minus RBC's. In addition to the blood vascular system all vertebrate possess a lymphatic system. It is colourless or yellowish fluid present in the lymph vessels. It is a mobile connective tissue like blood and is formed by the filtration of blood. This process involves the diffusion of substances from blood capillaries into the interstitial space which is, thus, the primary site of lymph formation. Two forces bring about a steady filtration of plasma fluid into the tissue spaces: capillary pressure (30-35 mm Hg) and colloid osmotic pressure in tissue fluid (8 mm Hg). After absorption by veins, a small amount of CO_2 and waste material still remains in the tissue fluid which is absorbed in the lymphatic capillaries as lymph. So, we can say that lymph is modified tissue fluid.

Table: 5.3-6 Differences between lymph and blood

S.No.	Characters	Blood	Lymph
(1)	RBC	Present	Absent
(2)	Blood platelets	Present	Absent
(3)	WBC	Present, generally 7000/cu mm	Present, generally 500-75000/cu mm
(4)	Plasma	Present	Present
(5)	Albumin : globulin	Albumin>Globulin	Albumin>Globulin
(6)	Fibrinogen	More	Less
(7)	Coagulation property	More	Less
(8)	Direction of flow	Two way, heart to tissues and tissues to heart	One way, tissues to heart
(9)	Rate of flow	Fast	Slow
(10)	Glucose, urea and CO ₂	Less	More

Hence, lymph can be represented as:

Lymph = Blood - [RBC + platelets + plasma proteins of high molecular weight]

Composition of lymph: Microscopic examination of lymph depicts that it contains a large number of leucocytes (mostly lymphocytes) ranging from 500 to 75,000 per *cubic mm*. No blood platelets present. The composition of the non cellular part of lymph (fasting) is as follows:

- (i) Water 94%
- (ii) Solids 6%
- (a) **Proteins :** Protein content is roughly half of the plasma and varies from 2.0-4.5%. It varies according to the part of the body from which it is collected, *i.e.* in liver 6%, in limb 2%, in intestinal part 4%. The varieties of proteins are found albumin, globulin and fibrinogen. In addition to this, traces of prothrombin, fibrinogen are also found.

- (b) **Fats**: In fasting condition fat content is low but after a fatty diet it may be 5.0 15%.
 - (c) Carbohydrates: Sugar, 132.2 mg per 100 ml.
- (d) Other constituents: Urea, creatinine, chlorides, phosphorus, calcium, enzymes and antibodies (120 ml./hour).
- Normally the rate of lymph formation is equal to the rate of its return to the blood stream. But occasionally the rate of lymph formation exceeds its return to the blood stream which causes accumulation of fluid around the cells resulting in dropsy or oedema.
- (2) **Lymphatic organs**: In human primary lymphatic (lymphoid) organs of the body are the Red bone marrow and Thymus gland. They are called primary lymphatic organs because they produce B and T cells the lymphocytes that carry out immune response. Haemopoietic stem cells in red bone marrow gives rise to B Cell and pre-T cells. Pre-T cells then migrate to thymus gland. Secondary lymphatic organs are the lymph nodes and spleen.
- (i) **Spleen**: Spleen is mesodermal in origin. Spleen is the largest solid mass of reticulo-endothelial tissue in the body. In human it measures about 12 cm (5 inch) in length and is situated in the left hypochondriac regions between the stomach and diaphragm. Like lymph nodes, spleen has hilus, where splenic artery, vein and efferent lymphatic vessels pass through. Spleen never filter lymph, because it has no afferent lymphatic vessel. Histologically it is formed by following structure –
- (a) Capsule: It is the outer covering of spleen formed of dense connective tissue and smooth muscles. The outer layer of the capsule is the serous coat formed of visceral peritoneum.
- (b) **Trabeculae:** Narrow fold like septa or trabeculae extend inwards from the capsule, dividing the spleen tissue into several incomplete lobules. They provide support and convey blood vessels into the interior of spleen.

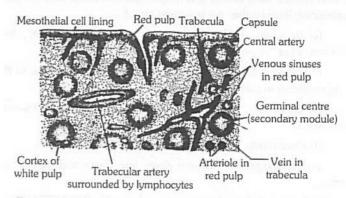

Fig: 5.3-15 Histological structure of spleen (Diagrammatic)

- (c) **Splenic pulp**: The reticulo-endothelial tissue is called splenic pulp. It contains a denser network of blood capillaries, small sinuses and fine blood vessels. The meshes of this network are studded with numerous splenic cells, red, blood corpuscles, macrophages and lymphocytes. The splenic pulp is of two distinct types
 - (i) White pulp
- (ii) Red pulp

In mammal embryos the red pulp contains myelocytes, erythroblast and also megakaryocytes. These types of cells are not present in adult spleen except in certain pathological condition.

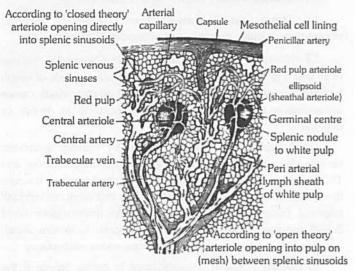

Fig: 5.3-16 Anatomy of circulation in a splenic lobule showing both closed circulation and open circulation (Diagrammatic)

Function: Although located close to the alimentary canal, the spleen has nothing to do with digestive system. it is, in fact, an important constituent of the reticuloendothelial system of body and performs the following functions:

- (a) Its macrophages engulf (= phagocytize) and destroy wornout blood corpuscles (RBC + platelets), dead and live pathogens, cell debris, pigment granules and other useless particulate materials, thus regularly cleaning the blood of its impurities.
- (b) It is active haemopoietic organ. In foetal life, the red pulp possess myeloblast, erythroblast and megakaryocytes. Hence, in foetus, it produces blood. In adults, the red pulp possess macrophages, plasma cells and lymphocytes. So, in adults, it is not producing blood rather it is screening blood.
- (c) In adults, it also serves as a sort of "blood bank". Its sinuses act as "reservoirs of blood".
- (d) White pulp of spleen functions in immunity as a site of B cell proliferation into antibody-producing plasma cells.
- (e) Spleen also acts as Graveyard or Slaughter house of worn out RBCs.
 - (f) Haemolysin is formed in spleen (Lysolecithin).
- (g) Haemoglobin is broken down into haem and globin by spleen.

Besides all these functions, the primary function of spleen is that it assists liver and helps in maintaining the composition of blood.

(ii) **Thymus gland :** In human thymus is located in mediastinum, between the lungs. The two thymic lobes divide into lobules by trabeculae. Each lobule consist of cortex and medulla. Cortex composed of tightly packed lymphocytes, epithelial cells, Macrophages. Pre-T cells migrates (via blood) from red bone marrow to thymus, where they proliferates and develop into mature T cells. Medulla consist of mostly of epithelial cells and

more widely scattered lymphocytes. Epithelial cells produce thymin hormone for maturation of T cells. Medulla also contain characteristic thymic (Hassall's) corpuscles, possibly, they are remnants of dying cells.

Lymphatic system in human

Lymph capillaries: Small, thin, lined by endothelium resting on a basement membrane and fine whose one end is blind and other end unites to form lymphatic ducts. These are present almost throughout the body but are absent in brain, eyeball, spinal cord, internal ear, bone marrow etc. Lymph capillaries in the region of small intestine in villi are called "lacteals" which collect chyle which is milky white in colour due to absorbed fat. Lacteals help in the absorption of digested fat.

Lymphatic ducts or vessels : Numerous, present in various parts of body. These vessels are like veins as they have all the three layers – tunica externa, tunica media and tunica interna, and are provided with watch pocket or semilunar valves but valves are more in number than veins. Valves are bicuspid.

Flow of lymph in lymphatics: Pulsations of lymph hearts in frog create sufficient force to maintain a steady flow of lymph in the lymphatic system. In mammals, the credit for maintaining onwards flow of lymph goes to (i) the "squeezing force" created by the skeletal muscles known as milking reaction (ii) the breathing movements of diaphragm and thoracic cage, (iii) mild peristalsis created by smooth muscles of the wall, of lymphatics themselves, and (iv) the pressure created by increasing amount of lymph in the lymphatics. Certain compounds like fats increase the rate of lymph flow and are called lymphata gogue. Blocking of lymph flow causes oedema.

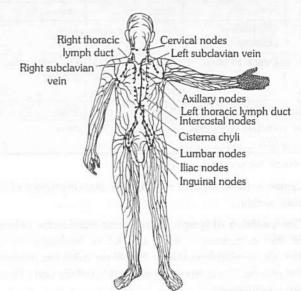

Fig: 5.3-17 Lymphatic system of mammals shown in man (ventral view)

Types of lymphatic ducts: Two main types:

(1) **Right lymphatic duct**: It is the smallest lymphatic duct with the length of approximately 1.25 cm. Its one end is blind and other one opens into right subclavian vein at the junction of right internal jugular vein. It collects lymph from one-fourth of the body (right part of head, neck, thoracic cavity and right arm).

UNIVERSAL BOOK DEPOT 1960

(2) Left lymphatic duct/thoracic duct: It is the longest lymphatic duct with the length of approximately 38-45 cm. It originates from cisterna chyli and empties into left subclavian vein. It collects lymph from three-fourth part of the body i.e. complete posterior part through cisterna chyli, left part of head, neck, thoracic cavity and left arms.

Cisterna chyli/Receptaculum chyli: It is a dilated sac like structure present below the diaphragm in lumbar region at the level of second lumbar vertebra. It collects lymph from posterior part of body i.e. abdomen, pelvic region and hind limbs and drains it in the left lymphatic duct.

It shows inflation and deflation due to the movement of diaphragm which is a passive movement. Hence, it is also called as passive lymphatic artery. It is also called as second heart.

Lymph nodes or lymph glands: These are the masses of lymphatic tissue and connective tissue (reticular tissue) and are located on the capillaries either solitary or in cluster. Where they are present solitary and in few number, such tissues are called diffused lymphatic tissues and where they are in clusters, they are called tonsils.

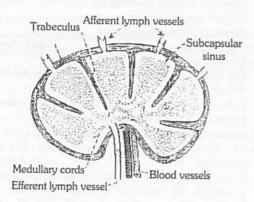

Fig: 5.3-18 Scheme to show some features of the structure of a lymph node

Lymphadenitis: During infection, central part of follicle shows rapid division and formation of plasma cells. hence, this part is also called reaction centre. The inflammation of lymph nodes in such condition is called Lymphadenitis.

Some of the common lymph nodes are — Axillary nodes (in armpits), genital (Inguinal) nodes (in pubic region), cervical nodes (in neck region), intercostal nodes (in chest region), lumbar nodes (in lumbar region), iliac nodes (in pelvic region) and peyer's patches (in small intestine). Besides these lymphatic nodes, a number of them are also present near major blood vessels (arteries), specially dorsal aorta.

☐ Tonsils: Clusters of lymph nodes. They are very often called as policemen. Various tonsils are — Normal tonsils (in pharynx), adenoid tonsils (in nasopharynx), abdominal tonsils (in vermiform appendix) and policeman of intestine (in lamina propria of ileum). Adenoid tonsils are present upto 7 years of age, then they are degenerated. Their swelling is called adenoid. Inflammation of tonsils is called Tonsilitis.

Haemal lymph node: In many animals some lymph nodes are found to possess red colour, due to the presence of blood in them. In man they are found in the retroperitoneal tissues and also in the mediastinum. Spleen may be regarded as the modified haemal lymph (haemolymph) node. Lymph nodes are located at intervals along its course.

Function of lymph nodes

- (i) They produce and supply lymphocytes to the blood and as a supportive function the trabeculae carry blood vessels which supply the node.
- (ii) They make screening of the lymph by means of phagocytic activity.
 - (iii) They serve a great defensive role against bacterial infections.
- (iv) They temporarily stop the spread of cancer cells as those cells have to penetrate through the lymph vessels to the lymph nodes from where they spread in the body.
- (v) They act as mechanical filters to resist the entrance of poisonous substances into circulation.
- (vi) They carry out immunological responses. They help in elaboration of antibodies and in the development of immunity.
 - (vii) Lymph nodes produce y-globulin.

Tips & Tricks

- Lymphatic system in class amphibia is of open type.
- ${\it Z}$ Lymph sinuses are the large spaces containing lymph. These are present in frog but absent in mammals.
- ∠ Lymph heart The heart which collects lymph.
- In frog, lymph hearts are two pairs an anterior pair and a posterior pair which collect lymph from respective regions. There are no lymph hearts in mammals.
- The process of lymph formation is called Transudation.
- Spleen is called "first reservoir" of blood while liver is called "second reservoir" of blood.
- Spleen, liver and kidneys all are called filter apparatus of blood.
- In AIDS, there occurs generalised swelling of all lymph nodes.
- Spleen is absent in cyclostomes.
- Cardiology Study of heart.
- Frank-Starling law The increase in strength of contraction as a result of stretching the walls of ventricle is known as starling's law of the heart.
- ∠ Largest sized heart is found in Blue whale and in elephant among the terestrial animals.

- Papillary muscles of ventricles are found only in the heart of mammals.
- Valves in heart were first reported by Fabricious.
- World's first heart transplant was performed by Dr. Christian Barnard on 55-year old Louis Wash kansky in Cape town, South Africa in the year 1967.
- ✓ India's first heart transplant was conducted by cardiac surgeon Dr. P. Venu Gopal in a 42-year old man Mr. Devi Ram on 3rd August, 1994 at AIIMS, Delhi
- ✓ Angina pectoris Severe but temporary heart pain of short duration which is usually felt in front of the chest and may pass into the arms specially left sided.
- Coronary thrombosis Formation of blood clot in coronary arteries of heart causing death of tissue and leading to heart attack or MI.
- Rheumatic heart Disease (RHD) Defects in heart valve due to toxins produced by throat infection caused by streptococcus leading to rheumatic fever and arthritis.
- Vasa vasorum are blood vessels which supply blood to the walls of great blood vessels.
- Ringer's solution is solution of chlorides of sodium, potassium, and calcium, discovered by Ringer in 1887.
- Artificial pacemaker is an electronic device with lithium halide battery, it was first developed by Greatbach and Chardack (1960).
- Splenic vein with maximum free Hb.
- Both pulmonary Aorta and a pair of umbilical artery (Human foetus) carry deoxygenated blood.
- Nereis among annelids and amphioxus among chordates have no heart.
- Ampullary hearts are found in crustaceans, insects and cephalopods.
- Pulsating hearts are found in annelids and mollusca.
- The heart of cockroach contracts with the help of alary muscles at a rate of 50 times/minute.
- ✓ In Unio (fresh water mussel), rectum passes through the heart and the wastes are discharged into the pericardial cavity by Keber's organ (also called pericardial gland)
- Circulatory system develops from the mesoderm in vertebrates.
- Gubernaculum cordis: White fibrous band which attaches apex of lizard heart to pericardium.
- Blood pressure was first measured by Halls in 1732.
- Bundle of His was discovered by a German Physiologist William His Jr. (1893).

- ✓ Plethysmograph: Device for finding variations in size of a part due to variation in amount of blood passing through or contained in the part.
- ✓ Wenckebach's Phenomenon: A form of incomplete heart block in which there is progressive lengthening of P-R interval.
- S.A. node is the pacemaker and A.V. node is the pace setter of heart.

Ordinary Thinking Objective Questions

Structure and function of heart

- The blood returning to the heart from lungs via pulmonary vein has more

 [AIIMS 1992; MP PMT 1994]
 - (a) RBC per ml of blood
 - (c) Haemoglobin per ml of blood
 - (c) Oxygen per ml of blood
 - (d) Nutrient per ml of blood
- 2. Systemic heart refers to [CBSE PMT 2003]
 - (a) The two ventricles together in humans
 - (b) The heart that contracts under stimulation from nervous system
 - (c) Left auricle and left ventricle in higher vertebrates
 - (d) Entire heart in lower vertebrates
- 3. The problem of electrical discontinuity caused in the normal heart by the connective tissue separating the atria from the ventricles is solved by [J & K CET 2012]
 - (a) Coordinating electrical activity in the atria with electrical activity in the ventricles by connecting them via the bundle of His
 - (b) Having the A-V node function as a secondary pacemaker
 - (c) Having an ectopic pacemaker
 - (d) Coordinating electrical activity in the atria with electrical activity in the ventricles by connecting them via the vagus nerve
- What is total diastolic time of ventricle in cardiac cycle [GUJCET 2015]
 - (a) 0.30 second
- (b) 0.40 second
- (c) 0.50 second
- (d) 0.10 second
- Which one of the following is a matching pair

[AIIMS 2003, 08; AMU (Med.) 2012]

- (a) Lubb sharp closure of AV valves at the beginning of ventricular systole
- (b) Dup sudden opening of semilunar valves at the beginning of ventricular diastole
- (c) Pulsation of the radial artery-valves in the blood vessels
- (d) Initiation of the heart beat Purkinje fibres
- In the heart of mammals the bicuspid valve (mitral valve) is situated between [NCERT; Manipal 1995; BHU 1999; VITEEE 2003; MP PMT 2005, 06; AFMC 2009]
 - (a) Left auricle and left ventricle
 - (b) Post caval and right caval
 - (c) Right auricle and left auricle
 - (d) Right ventricle and pulmonary aorta

(d) Venous blood is returned to the left auricle

	choose the right option		(d) Transfer of impulses
	A. Human heart is an ectodermal derivative	25.	The volume of blood each ventricle pumps out during a
			cardiac cycle is about [Kerala PMT 2011]
	B. Mitral valve guards the opening between the right atrium and left ventricle		(a) 70 ml (b) 5000 ml
			(c) 71 (d) 1200 ml
	 SAN is located on the left upper corner of the right atrium 		(e) 40 ml
		26.	Which one of the statement is correct with reference to the
	D. Stroke volume × Heart rate = Cardiac output		circulation of blood in a mammal
	[NCERT; BHU 2004; AMU (Med) 2005; Kerala PMT 2012]		(a) Left auricle receives oxygenated blood from the lungs
	(a) A alone is correct		(b) Pulmonary artery returns oxygenated blood from the
	(b) A and B alone are correct		lungs to the left auricle
	(c) B and C alone are correct		(c) Pulmonary vein carries venous blood from right auricle
	(d) D alone is correct		to lungs

(e) B and D above are correct

(a) Renin

866 Body Fluids and Circulation

- The typical Lubb-Dup sounds heard in the heart beat of a healthy person are due to [CBSE PMT 1994; KCET 1994; MP PMT 2011; WB JEE 2012; AIPMT 2015] (a) Closing of the tricuspid and bicuspid valve (b) Blood flow through the aorta (c) Closing of the tricuspid and semilunar valves (d) Closing of the semilunar valves
- The increase in blood flow to heart stimulates secretion of 28. [MHCET 2015] (b) Oxytocin
- (d) Atrial natriuretic factor (c) Antidiuretic hormone Pace maker (S.A. Node) of the heart is situated 29. MP PMT 1994, 95; BVP 2000; AIIMS 2004; Pb PMT 2004; Wardha 2005; DPMT 2006]
 - (a) In wall of right atrium close to eustachian valve
 - (b) On intra-auricular septum
 - (c) On inter-venticular septum (d) In wall of left atrium close to the opening of pulmonary
- veins [NCERT; MP PMT 1994] 30. During systole (a) Auricles and ventricles contract simultaneously
 - (b) Auricles and ventricles contract separately
 - Only auricles contract (c)
- (d) Only ventricles contract
- Right auricle of mammalian heart receives blood from [MP PMT 1994, 96]
 - (b) Pulmonary veins (a) Sinus venosus (d) Pre and postcavals
- (c) Precavals During ventricular diastole 32.
 - [MP PMT 1994; PET (Pharmacy) 2013]
- (b) The heart contracts (a) The auricles relax
 - (c) The heart pumps blood (d) The ventricles relax
- The following figure shows human heart. Which labelled structure represents the bundle of His [NCERT]
 - (a) IV (b) III (c)
- 34. In humans, blood passes from the post caval to the diastolic [CBSE PMT 2008] right atrium of heart due to
 - (a) Stimulation of the sino auricular node
 - (b) Pressure difference between the post caval and atrium
 - (c) Pushing open of the venous valves
 - (d) Suction pull
- Open circulatory system is present in
 - (A) Arthropods (Insects) (B) Annelids
 - (C) Chordates
- (D) Molluscs
- INCERT: KCET 1999; Kerala PMT 2008]
- (a) Conly
- (b) C and B
- A and B (c)
- (d) Donly
- (e) A and D
- Blood enters the heart because muscles of the 36.
 - [Odisha JEE 2009]
 - Atrium contracts
- (b) Atrium relaxes
- Ventricle relaxes
- (d) Ventricle contracts
- The function of vagus nerve innervating the heart is to 37.
 - [DUMET 2009]
 - (a) Initiate the heart beat
- (b) Reduce the heart beat
- (c) Accelerate the heart beat (d) Maintain constant heart beat

An oval depression called fossa ovalis is seen on

[Kerala PMT 2009]

- (a) Inter atrial septum
- Inter ventricular septum (b)
- Right auriculo-ventricular septum (c)
- Left auriculo-ventricular septum
- (e) Papillary muscles
- Which of the following statements is related to Starling's law 39.
 - (a) Greater the stroke volume greater is the heart rate
 - Greater the initial length of the cardiac muscle fibre, more is the force of contraction of heart
 - Greater the minute volume, greater is the heart rate
 - Lesser the length of cardiac muscle fibre greater is the force of contraction of heart
- [AFMC 1994] Heart beats are accelerated by
 - (a) Cranial nerves and acetylcholine
 - Sympathetic nerves and acetylcholine
 - Cranial nerves and adrenaline (c)
 - (d) Sympathetic nerves and epinephrine
- JG cells, under low glomerular blood flow, release 41.
 - [Kerala PMT 2008] (b) Angiotensin II
 - (a) Angiotensin I (c)
 - (d) Aldosterone Renin
 - (e) ADH
- The triangular sac like structure which receives blood 42. [Kerala PMT 2012] through the vena cava in frog is Or
 - Which of the following structure is absent in rabbit's heart [RPMT 1995]
 - Sinus venosus (a) Ventricle
 - (d) Conus arteriosus (c) Hepatic portal system
 - (e) Left auricle
- Which of the following parts of heart first receives [BHU 2008]
- deoxygenated blood
 - [Odisha JEE 2010] Tricuspid valve is present in
 - (a) Right ventricle (b) Left auricle (d) Left ventricle (c) Right auricle
- The duration of cardiac cycle is INCERT: 44. J & K CET 2008; WB JEE 2009, 10; BHU 2012]
 - (b) 0.8 µ sec 0.8 sec (c) 0.08 sec (d) 0.008 sec
- 'Bundle of His' is a part of which one of the following [NCERT; CBSE PMT (Pre.) 2011] organs in humans
 - (b) Brain (a) Pancreas
 - (d) Kidney (c) Heart First heart sound occurs at
 - [RPMT 1999; CBSE PMT 2000; BHU 2008]
 - (a) Opening of semilunar valve (b) Closing of semilunar valve (c) Onset of auricular systole (d) Sudden closure of A.V. valves
- An artificial pace-maker is implanted subcutaneously and [AIIMS 2004, 07]
 - connected to the heart in patients (a) Having 90% blockage of the three main coronary arteries
 - (b) Having a very high blood pressure
 - With irregularity in the heart rhythm
- (d) Suffering from arteriosclerosis When the heart beat increases the condition is called 48.
 - (b) Tachycardia (a) Bradycardia (d) Cardiac arrest (c) Leucopenia
- If due to some injury the chordae tendinae of the tricuspid valve of the human heart is partially non-functional, what will be the immediate effect [CBSE PMT (Pre.) 2010]
 - (a) The flow of blood into the pulmonary artery will be reduced
 - The flow of blood into the aorta will be slowed down
 - The 'pacemaker' will stop working
 - (d) The blood will tend to flow back into the left atrium

Human heart is enclosed in a double walled sac called

[HP PMT 2005]

- (a) Peritome
- (b) Pericardium
- Pericardial sinus 51. 'Heart of Heart' is
- (d) Perineural sinus
 - [NCERT; BHU 2005, 08]

Or

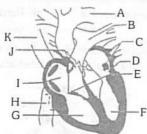

Pace maker of the heart is

- [CPMT 1995, 98; BHU 2006; WB JEE 2011]
- (a) SA node
- (b) AV node
- (c) Bundle of His 52. Spiral valve is present in
- (d) Purkinje fibres [MH CET 2000]
- (b) Left auricle
- (a) Right auricle (c) Right ventricle
- (d) Truncus arteriosus
- 53. Which one is the correct route through which pulse making impulse travels in the heart [NCERT; KCET 1994, 2004, 05; CBSE PMT 1995; Kerala PMT 2007; WB JEE 2011]
 - (a) SA node \rightarrow Purkinje fibres \rightarrow Bundle of His \rightarrow AV node → Heart muscles
 - (b) AV node → SA node → Purkinje fibres → Bundle of His → Heart muscles
 - (c) AV node → Bundle of His → SA node → Purkinje fibres → Heart muscles
 - SA node → AV node → Bundle of His → Purkinje fibres → Heart muscles
- 54. The given diagram shows the human heart. Which site represents the generation of action potential in human heart

- (a) IV
- (b) III
- (c) II

(d) I

- [NCERT]
- 55. See the figure of the vertical section of human heart given below certain parts have been indicated by letters. Select the correct answer in which these letters have been correctly paired with parts they indicate

- (a) A Aorta; B Superior vena cava, C Inferior vena cava; D - Left ventricle; E - Semilunar valves; F - Left auricle; G -Right auricle; H - Pulmonary artery; I - Right ventricle; J - Tricuspid valves; K - Pulmonary vein
- (b) A Aorta; B Superior vena cava, C Inferior vena cava; D - Right ventricle; E - Tricuspid and Mitral valves; F - Right auricle; G -Left auricle; H - Pulmonary vein; I - Left ventricle; J - Semilunar valves; K -Pulmonary artery
- (c) A Aorta; B Pulmonary artery, C Pulmonary vein; D - Left auricle; E - Tricuspid and Mitral valves; F - Left ventricle; G - Right ventricle; H - Inferior vena cava; I -Right auricle; J - Semi lunar valves; K - Superior vena
- (d) A Aorta; B Pulmonary vein, C Pulmonary arteries; D - Left ventricle; E - Semilunar valves; F - Left auricle; G - Right auricle; H - Superior vena cava; I -Right ventricle; J - Tricuspid valves; K - Inferior vena cava

56. Which of the following statements is false [Manipal 1995]

- (a) Blood from the right side of the heart is carried to the lungs by the pulmonary artery
- (b) The term pleura refers the double layered covering of the kidney
- (c) Pancreas is both an exocrine and endocrine gland
- (d) Scurvy is caused by the deficiency of vitamin C
- 57. The pace-setter in the heart is called [CBSE PMT 1994]
 - (a) Purkinje fibres
 - (b) Sino-aterial node (SAN)
 - Papillary muscle
 - (d) Atrio-ventricular node (AVN)

Largest heart is found in

- [AFMC 1996]
- (a) Elephant
- (b) Giraffe
- (c) Crocodile
- (d) Lion
- Average cardiac output is
- [MP PMT 1996; WB JEE 2012]
- (a) 4 litres per minute
- (b) 6.3 litres per minute
- (c) 5.3 litres per minute
- (d) 7.3 litres per minute
- Alary muscle is associated with [CPMT 2002; RPMT 2005]
 - (a) Heart and circulation
 - (b) Malpighian tubules and excretion
 - (c) Trachea and respiration
 - (d) None of the above
- Which diagram shows the correct blood circulation

[NCERT; GUJCET 2014]

Diagram 1

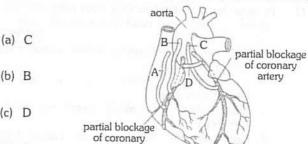

Diagram 2

Diagram 3

- (a) Diagram 1
- (b) Diagram 2
- (c) Diagram 3 (d) Diagram 4
- 62. The chamber of human heart, which has thickest wall
 - [JIPMER 1994; Kerala PMT 2004; WB JEE 2010]
 - (a) Right atrium
- (b) Left atrium
- (c) Right ventricle
- (d) Left ventricle
- (e) None of these
- Which tube in the given figure of a heart correctly represents the result of a successful coronary bypass operation [NCERT]

artery

(b) B

(c) D

(d) A

64. The given figure indicates three stages in the cardiac cycle

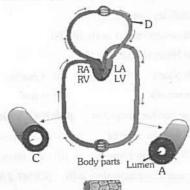

[NCERT]

Choose the correct sequence

(a) 3, 1, 2

(b) 2, 1, 3

- (c) 1, 2, 3
- (d) 2, 3,1
- Figure shows blood circulation in humans with labels A to D. Select the option which gives correct identification of label and functions of the part

[NEET (Karnataka) 2013]

- (a) B Capillary thin without muscle layers and well two cell thick
- (b) C Vein thin walled and blood flows in jerks/spurts
- D Pulmonary vein takes oxygenated blood to heart $PO_2 = 95 \text{ mm Hg}$
- (d) A Artery thick walled and blood flows evenly
- The wall of heart is made up of

[MP PMT 1997] (b) Myocardium

- (a) Epicardium (c) Endocardium
- (d) All of the above
- Heart beats are affected by
- [MP PMT 1998]
- (a) Carbon dioxide
- (b) Oxygen
- (c) Vagus nerve
- (d) All the above
- Heart beat originates from 68.
- INCERT: CMC Vellore 1993; MP PMT 1998; CBSE PMT 2002]
 - (a) Pacemaker
- (b) Cardiac muscles
- (c) Left atrium
- (d) Right ventricle
- In the evolution of animals a heart to pump the blood is [Kerala CET 2003] found for the first time in
 - (a) Annelids
- (b) Roundworms
- (c) Arthropods
- (d) Flat worms
- Which of the following is different from others in absence of [CPMT 1999; JIPMER 2001] muscular coat
 - (a) Veins
- (b) Arteries
- (c) Capillaries
- (d) Arterioles
- In order for the blood to flow from right ventricle to left 71. ventricle in mammalian heart, it must flow through
 - [DUMET 2010]
 - Right ventricle, pulmonary arteries, Lungs, Pulmonary veins, Left atrium
 - (b) Right ventricle, Pulmonary veins, Lungs, Pulmonary arteries, Left atrium
 - (c) Right ventricle, Right atrium, Lungs, Pulmonary veins,
 - (d) Right ventricle, Systemic aorta, Lungs, Pulmonary veins, Left atrium

The heart of a crocodile consists of

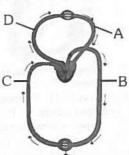

[KCET 2002;

RPMT 2002; AIEEE Pharmacy 2003; BVP 2004]

- (a) A single auricle and two ventricles
- (b) Two auricles and a single ventricle
- (c) Two auricles and two ventricles
- (d) A single auricle and a single ventricle
- The post-caval is constituted by

[Pune CET 1998]

- Renal, gonadial and hepatic
- (b) Renal and gonadial
- Gonadial and hepatic
- (d) Hepatic and renal
- [Pune CET 1998] The pre-caval vein is formed of
 - (a) External jugular and innominate
 - (b) Innominate and subclavian
 - (c) External jugular, innominate and subclavian
 - (d) External jugular and subclavian
- The post-caval vein collects blood from [Pune CET 1998]
 - (a) Hind limbs
 - (b) Hind limbs and organs of the body cavity
 - (c) Body cavity organs
 - (d) Renal organs
- The pre-caval veins collect blood from [Pune CET 1998] 76.
 - (a) Trunk and hind limbs
- (b) Fore limbs and hind limbs
- (c) Head and fore limbs
- (d) Head and hind limbs
- [Pune CET 1998] 77. The two branches of the iliac artery are
 - (a) Femoral and renal
 - (b) Femoral and sciatic
 - (c) Vesiculo-epigastric and femoral
 - (d) Renal and sciatic
- 78. The unpaired systemic branch is
- [Pune CET 1998]
 - (a) Coeliaco-mesentric
- (b) Renal artery
- (d) Vesiculo-epigastric
- Figure shows schematic plan of blood circulation in humans with labels A to D, Identify the label and give its function/s

[NEET 2013]

- (a) D-Dorsal aorta-takes blood from heart to body parts, $PO_2 = 95 \, \text{mm Hg}$
- (b) A-Pulmonary vein-takes impure blood from body parts, $PO_2 = 60 \, \text{mm Hg}$
- (c) B-Pulmonary artery-takes blood from heart to lungs, $PO_2 = 90 \, \text{mm Hg}$
- (d) C-Vena Cava-takes blood from body parts the right auricle, $PCO_2 = 45 mm Hg$

- 12. Blood pressure increases and heart rate decreases in response to [AIIMS 2001]
 - (a) Exercise
- (b) Haemorrage
- (c) Exposure to high altitude (d) Increased intracranial pressure
- Which one of the following statement is correct regarding blood pressure [NCERT; CBSE PMT (Pre.) 2011] (a) 190/110 mmHg may harm vital organs like brain and kidnev
 - (b) 130/90 mmHg is considered high and requires treatment
 - 100/55 mmHg is considered and ideal blood pressure
 - (d) 105/50 mmHg makes one very active
- 14. Deficiency of which of the following causes obesity, low plasma Na^+ , high K^+ and increased blood pressure

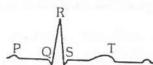

[CPMT 1999; JIPMER 2001]

- (a) Growth hormone
- (b) Adrenaline
- (c) Cortisol
- (d) Thyroxine
- 15. During systole of ventricle
- [MP PMT 1995]
- (a) Blood enters the heart (b) Blood leaves the heart
- (c) Blood leaves the ventricle (d) Blood enters lungs
- We feel sleepy just after taking meals because [CPMT 1996]
 - (a) Blood pressure increases (b) Blood pressure decreases (c) Body weight increases (d) We feel lethargic
- During diastole

- [MP PMT 1996] (b) Blood leaves the ventricle
- (a) Blood enters lungs
- (c) Blood leaves the heart (d) Blood enters the heart
- If the systolic pressure is 120 mm Hg and diastolic pressure 18. is 80 mm Hg, the pulse pressure is

[MHCET 2006; WB JEE 2010; KCET 2010]

- (a) $120 \times 80 = 9600 \, mm \, Hg$ (b) $120 + 80 = 200 \, mm \, Hg$
- (c) 120 80 = 40 mm Hg (d) $\frac{120}{80} = 1.5 \text{ mm Hg}$
- The diagram given here is the standard ECG of a normal person. The P-wave represents the

[CBSE PMT (Mains) 2011; NEET 2013]

- (a) End of systole
- (b) Contraction of both the atria
- (c) Initiation of the ventricular contraction
- (d) Beginning of the systole

20. Blood pressure in the pulmonary artery is

[NEET (Phase - I) 2016]

[MP PMT 1999]

- (a) Same as that in the aorta
- (b) More than that in the carotid
- (c) More than that in the pulmonary vein
- (d) Less than that in the venae cavae
- A decrease in blood pressure/volume will not cause the release of [NEET 2017]
 - (a) Renin
- (b) Atrial natriuretic Factor
- (c) Aldosterone
- (d) ADH

Lymphatic system

- Lymph (nodes) glands form
- (b) Lymphs
- (a) Hormones
- (d) Antibodies
- (c) Antigens
 - Which of the following is first to receive lymphatic duct from legs [GUJCET 2007]
 - (a) Left subclavian vein
- (b) Right subclavian vein
- (c) Right lymphatic duct
- (d) Thoracic lymphatic duct
- 3. Lymph is colourless because
- [MP PMT 1999] (b) WBC are present
- (a) WBC are absent (c) Haemoglobin is absent
 - (d) RBC are absent
- Which organ is considered as "Graveyard of RBC" where most of them are destroyed by macrophages

AFMC 2001; AMU (Med.) 2006;

CBSE PMT (Mains) 2012]

Which of the following organs can be called as a sort of "blood bank"

- (a) Red bone marrow
- (b) Spleen
- (c) Kidney
- (d) Intestine
- 5. Which of the following is not a major organ of lymphatic [MP PMT 2010; AFMC 2012]
 - (a) Lymph nodes
- (b) Thymus
- (c) Kidney
- (d) Spleen
- An antibody is a
- [MP PMT 1996; BVP 2003]
- (a) Molecule that specifically inactivates an antigen (b) WBC which invades bacteria
- (c) Secretion of mammalian RBC
- (d) Component of blood
- Antigens are present
- [CBSE PMT 1995]
- (a) Inside nucleus
- (b) On cell surface (d) On nuclear membrane
- (c) Inside cytoplasm 8.
 - Function of human spleen is to
 - (b) Secrete hormone
 - (a) Control the pulse rate (c) Stimulate heart
- (d) Control blood volume
- (a) Thymus
- T-Lymphocytes originate from [MP PMT 2001; WB JEE 2009]
 - (c) Liver
- (b) Bone marrow (d) None of these
- Lymphoid tissue is found in
- [CPMT 2000; BHU 2006]
- (a) Thymus
- (b) Tonsils
- (c) Lymph nodes
- (d) All of these
- 11. If the spleen is removed from the body of an adult man then
 - (a) Antibody production will be less
 - (b) RBC production will be lowered
 - (c) WBC production will be lowered
 - (d) Filtration of dead RBC will stop

- [CBSE PMT 1991] Red pulp and white pulp are found in (b) Spleen (a) Bone (d) Skeletal Muscle (c) Tooth [CBSE PMT 2001; BVP 2001] Spleen is (b) Lymphoid (a) Haemopoeitic (d) Celluloid Reproductive The principle function of the lymph node in the man is (a) Destruction of old RBC

 - (b) Destruction of old WBC
 - (c) Collection and destruction of pathogens in the blood
 - (d) Production of WBC
- The lymph serves to 15.

[CBSE PMT 1995; BHU 2004]

- (a) Transport O2 to the brain
- (b) Transport CO2 to the lungs
- (c) Return the interstitial fluid to the blood
- (d) Return the WBCs and the RBCs to the lymph nodes
- 16. Humoral antibodies are produced by
 - (a) B-cells
- (b) T cells
- (c) Globulins
- (d) Plasma cells
- 17. If thymus gland of an infant is removed which of the [CPMT 1993] following will not form
 - (a) T lymphocytes
- (b) β lymphocytes
- (c) Erthryocytes
- (d) Granulocytes
- Which vertebrate organ receives only oxygenated blood 18.

[KCET 2001]

- (a) Gill
- (b) Lung
- (c) Spleen
- (d) Liver
- [BHU 2001] Lymph vessels are united to form 19.
 - (a) Lymph heart
- (b) Cisterna chyle
- (c) Thoracic duct
- (d) Jugular vein
- [CBSE PMT 1996] Immunoglobulins are produced by 20.
 - (a) Lymphocytes
- (b) Spleen
- (c) Leucocytes
- (d) Monocytes

Portal system

- A portal system is a system in which
 - (a) A vein starts from an organ and ends up in heart
 - (b) An artery breaks up in an organ and restarts by the union of its capillaries
 - The blood from the gut is brought into the kidney before it is poured into posterior venacava
 - (d) A vein breaks up in an organ into capillaries and restarts by their union as a new vein in the same organ
- A vein that collects blood from one network of capillaries 2. and transports it directly to a second capillary network in another region of the body, without returning to the heart is [Odisha JEE 2010; WB JEE 2012] called
 - (a) Coronary vein
- (b) Pulmonary vein
- (c) Portal vein
- (d) Carotid vein
- 3. Hepatic portal system starts from
- [NCERT]
- (a) Digestive system to liver (b) Kidney to liver
- (c) Liver to heart (d) Liver to kidney
- Which of the following vessel in rabbit starts with capillaries 4. [RPMT 2002] and ends in capillaries

Or

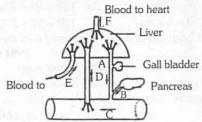

Which one of the following vein breaks up into capillaries

[MP PMT 1992]

- (a) Pulmonary artery
- (b) Renal vein
- (c) Hepatic portal vein
- (d) Renal artery

- Blood circulation that starts in capillaries and ends in 5. [NCERT; J & K CET 2010] capillaries is called
 - (a) Portal circulation
- (b) Hepatic circulation

- (c) Cardiac circulation
- (d) None
- The diagram below show how things get to and from the liver. They are labelled as A, B, C, D, E and F. Which one of the following labellings is the correct one [Kerala PMT 2004]

- (a) A is the hepatic portal vein and E is the hepatic vein
- (b) C is the intestine and F is the hepatic portal vein
- (c) D is the hepatic portal vein and F is the hepatic vein
- (d) B is pancreatic artery and E is the hepatic artery
- (e) D is the hepatic portal vein and E is the hepatic vein
- Which of the following carries glucose from digestive tract to 7. [CBSE PMT 1999; BHU 2001]
 - (a) Hepatic artery
- (b) Hepatic portal vein
- (c) Pulmonary vein
- (d) None of these
- [Pune CET 1998] The renal portal system is made of
 - (a) Femoral, renal portal veins
 - (b) Sciatic, renal portal veins
 - (c) Renal portal veins
 - (d) Femoral, sciatic, renal portal veins
- The hepatic portal vein drains blood to liver from

[NEET 2017]

- (a) Heart
- (b) Stomach
- (c) Kidneys
- (d) Intestine

Exemplar Questions

- Mark, among the following a cell which does not exhibit [NCERT] phagocytotic activity
 - (a) Monocytes
- (b) Neutrophil
- (c) Basophil
- (d) Macrophage
- One of the common symptoms observed in people infected [NCERT] with Dengue fever is
 - (a) Significant decrease in RBC count
 - (b) Significant decrease in WBC count
 - (c) Significant decrease in platelets count
 - (d) Significant increase in platelets count
- Which among the followings is correct during each cardiac 3. [NCERT] cycle
 - (a) The volume of blood pumped out by the Rt and Lt ventricles is same
 - (b) The volume of blood pumped out by the Rt and Lt ventricles is different
 - (c) The volume of blood received by each atrium is different
 - (d) The volume of blood received by the aorta and pulmonary artery is different

UNIVERSAL BOOK DEPOT 1960

- 4. Cardiac activity could be moderated by the autonomous neural system. Tick the correct answer [NCERT]
 - (a) The parasympathetic system stimulates heart rate and stroke volume
 - (b) The sympathetic system stimulates heart rate and stroke volume
 - (c) The parasympathetic system decreases the heart rate but increase stroke volume
 - (d) The sympathetic system decreases the heart rate but increase stroke volume
- Mark the pair of substances among the following which is essential for coagulation of blood [NCERT]
 - (a) Heparin and calcium ions
 - (b) Calcium ions and platelet factors
 - (c) Oxalates and citrates
 - (d) Platelet factors and heparin
- 6. ECG depicts the depolarization and repolarisation processes during the cardiac cycle. In the ECG of a normal healthy individual one of the following waves is not represented

[NCERT]

- (a) Depolarisation of atria (b) Repolarisation of atria
- (c) Depolarisation of ventricles (d) Repolarisation of ventricles
- 7. The cells involved in inflammatory reactions are [NCERT]
 - (a) Basophils
- (b) Neutrophils
- (c) Eosinophils
- (d) Lymphocytes
- 8. The second heart sound (dubb) is associated with the closure of [NCERT]
 - (a) Tricuspid valve
 - (b) Semilunar valves
 - (c) Bicuspid valve
 - (d) Tricuspid and bicuspid valves
- Which of the following correctly explains a phase/event in cardiac cycle in a standard electrocardiogram [NCERT]
 - (a) QRS complex indicates atrial contraction
 - (b) QRS complex indicates ventricular contraction
 - (c) Time between S and T represents atrial systole
 - (d) P-wave indicates beginning of ventricular contraction
- 10. Which of the following statements is incorrect [NCERT]
 - (a) A person of 'O' blood group has anti 'A' and anti 'B' antibodies in his blood plasma
 - (b) A person of 'B' blood group can't donate blood to a person of 'A' blood group
 - (c) Blood group is designated on the basis of the presence of antibodies in the blood plasma
 - (d) A person of AB blood group is universal recipient
- What would be the cardiac output of a person having 72 heart beats per minute and a stroke volume of 50 ml

[NCERT]

- (a) 360 mL
- (b) 3600 mL
- (c) 7200 mL
- (d) 5000 mL
- 12. Match the terms given under Column 'A' with their functions given under Column 'B' and select the answer from the options given below

Column 'A'

Column 'B'

- A. Lymphatic system
- i. Carries oxygenated blood
- B. Pulmonary vein
- ii. Immune Response
- C. Thrombocytes iii. To drain back the tissue fluid to the circulatory
- D. Lymphocytes
- fluid to the circulatory system
- D. Lymphocytes Options
- iv. Coagulation of blood
- Options (NCERT)
 (a) A-ii, B-i, C-iii, D-iv (b) A-iii, B-i, C-iv, D-ii
- (c) A-iii, B-i, C-ii, D-iv (d) A-ii, B-i, C-iii, D-iv

- 13. Read the following statements and choose the correct option
 [NCERT]
 - Statement 1: Atria receive blood from all parts of the body which subsequently flows to ventricles.
 - Statement 2: Action potential generated at sino-atrial node passes from atria to ventricles.
 - (a) Action mentioned in Statement 1 is dependent on action mentioned is Statement 2
 - (b) Action mentioned in Statement 2 is dependent on action mentioned in Statement 1
 - (c) Action mentioned in Statements 1 and 2 are independent of each other
 - (d) Action mentioned in Statements 1 and 2 are synchronous

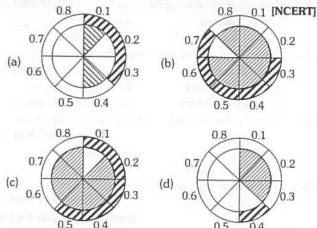

Critical Thinking

Objective Questions

Blood of Periplaneta does not carry oxygen because

[RPMT 2001]

- (a) O₂ is transported by respiratory tubules
- (b) Its respiration is anaerobic
- (c) There is no cells in its blood
- (d) Periplaneta does not has any blood vessel
- 2. A vein differs from the artery in having
- [CBSE PMT 1993; MP PMT 1993, 94; Pb. PMT 2000]
 - (a) Narrow lumen
 - (b) Strong cuticular and muscular wall
 - (c) Valves to control direction of flow
 - (d) Dark pigmented wall
- Which of the following diagram of cardiac cycle is possible in case of human heart, if the shaded and nonshaded sectors represents different events (systole or diastole)

- 4. pH of blood in artery and vein is
 - (a) Same
 - (b) More in artery and less in vein
 - (c) More in vein and less in artery
 - (d) Not definite
- 5. Largest blood vessel in body is

[MP PMT 1993; MHCET 2000]

- (a) Carotid artery
- (b) Dorsal aorta
- (c) Phrenic artery
- (d) Coronary artery
- 6. All arteries carry oxygenated blood except

[MP PMT 2001; AFMC 2003]

- (a) Systemic
- (b) Hepatic
- (c) Pulmonary
- (d) Cardiac

- Choose the correct proportion with respect to the distribution of blood in the body of man. [Kerala PMT 2004]
 - (a) 5% to heart muscles, 15% to brain, 25% to liver, 25% kidney, 15% to bones, 15% to other organs
 - (b) 20% to heart muscles, 10% to brain, 10% to liver, 25% to kidney, 10% to bones, 25% to other organs
 - (c) 10% to heart muscles, 10% to brain, 10% to liver, 40% to kidney, 15% to bones, 15% to other organs
 - (d) 5% to heart muscles, 20% to brain, 20% to liver, 15% to kidney, 5% to bones, 35% to other organs
 - (e) 1% to heart muscles, 20% to brain, 30% to liver, 40% to kidney, 5% to bones, 40% to other organs
- **8.** Given below are four statements (A-D) regarding human blood circulatory system
 - (A) Arteries are thick-walled and have narrow lumen as compared to veins
 - (B) Angina is acute chest pain when the blood circulation to the brain is reduced
 - (C) Persons with blood group AB can donate blood to any person with any blood group under ABO system
 - (D) Calcium ions play a very important role in blood clotting

Which two of the above statements are correct

[NCERT; CBSE PMT (Mains) 2010]

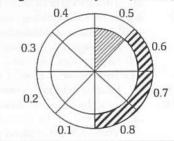

- (a) (A) and (D)
- (b) (A) and (B)
- (c) (B) and (C)
- (d) (C) and (D)
- Heaviness with severe chest pain which may disappear with rest indicates [MHCET 2015]
 - (a) Angina pectoris
- (b) Atherosclerosis
- (c) Arteriosclerosis
- (d) Hyperthyroidism
- 10. In haemoglobin iron is present in
- [CBSE PMT 1992]
- (a) Ferrous form
- (b) Ferric form
- (c) Metallic form
- (d) Any form
- Mixing up of arterial and venous blood does not take place in a heart having [AIIMS 1992]
 - (a) Two chambers
- (b) Four chambers
- (c) Three chambers
- (d) None of the above
- 12. When the right ventricle contracts the blood goes into
 - [CBSE PMT 1992]

- (a) Aorta
- (b) Brain
- (c) Pulmonary artery
- (d) None
- Trilobed valve present between right atrium and ventricle in mammalian heart is [NCERT; CBSE PMT 1993; AFMC 2008; Kerala PMT 2008]
 - (a) Triac
- (b) Triad
- (c) Tricuspid or besian
- (b) Trigeminal
- 14. Stimulation of the vagus nerve will make the heart beat
 - (a) Faster
- (b) 70 times/minute
- (c) Slower
- (d) Normal
- 15. The rate of heart beat per minute is highest in case of
 - (a) Elephant
- (b) Whale
- (c) Man
- (d) Mouse
- **16.** Which one of the following animals has two separate circulatory pathways [AIPMT 2015]
 - (a) Lizard
- (b) Whale
- (c) Shark
- (d) Frog

17. Which one represents pulmonary circulation

[NCERT; Kerala PMT 2002]

- (a) In auricle (oxygenated blood) lungs (deoxygenated blood) – Right auricle
- (b) Left auricle (deoxygenated blood) lungs (oxygenated blood) Right auricle
- (c) Left auricle (oxygenated blood) lungs (deoxygenated blood) – Left auricle
- (d) Right auricle (deoxygenated blood) lungs (oxygenated blood) – Left auricle
- Mammals have biconcave RBC. The physiological use for it is [NCERT]
 - (a) To decrease the surface area
 - (b) To increase the surface area
 - (c) To be packed like coins
 - (d) None of the above
- 19. Systole refers to the contraction of
 - of [BHU 2002]
 - (a) SA node
- (b) AV node
- (c) Major arteries
- (d) Atria and ventricles
- 20. Which set is correct
- [CBSE PMT 2001]
- (a) Sebum Analgesic
 - (b) Vitamin Nicotine
 - (c) Corpuscallosum Graffian follicle
 - (d) Bundle of His Purkinje fibre
- 21. In rabbit, function of spleen is
- [CPMT 1995]
 (b) Respiration
 - (a) Blood purification(c) Excretion
- (d) None of the above
- 22. See the following Cardiac Cycle. For how much duration does joint systole occur in the given cardiac cycle [NCERT]
 - (a) 0.4 seconds
 - (b) 0.7 seconds
 - (c) 0.3 seconds
 - (d) None

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below :

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- 1. Assertion : Heart valves resemble swing doors in action.
 - Reason : Valves are present in the heart chamber, at the opening of the heart into large arteries and veins.
- Assertion : WBCs accumulate at the site of wounds by diapedesis.
 - Reason : It is the sqeezing of leucocytes from the endothelium. [AIIMS 2002]

Answers and Solutions

Structure and function of heart

- (a) Lubb is the first, low pitched heart sound produced due to the closure of bicuspid and tricuspid valves at the start of ventricular systole.
- 6. (a) The bicuspid valve is a valve consisting of two membranous flap or cups situated between the atrium and ventricle of the left side of the heart in mammals.
- 10. (d) The heart of cockroach is pulsatile and formed of 13 inverted funnel-shaped segmental chamber, each chamber (except last one) has a pair of apertures called ostia which open into the pericardial sinus.
- 16. (d) The amount of blood flowing from the heart over a given period of time is known as the cardiac output. It depends upon the heart rate and stroke volume.
 Cardiac output = stroke volume × heat rate
- (a) The left atrium receives oxygenated blood from the lungs through four of pulmonary veins.
- (a) Within the lateral walls of ventricles and help in conduction of cardiac impulse.
- 21. (a) Pericardium (Protective covering) and pericardial fluid protects the heart from shocks, mechanical injuries and keeps it moist and also allows free movements of the heart.
- 22. (a) The chordae tendineae or heart strings are cord like tendons that connect the papillary muscles to the tricuspid valve and the mitral valve in the heart. The chordae tendinae prevents the flaps from being everted upto the right atrium, these cord like tendons hold in position other flaps such as bicuspid or mitral valve.
- 27. (c) First sound is 'lubb' a long and booming sound (related by the closure of tricuspid valve and second sound is 'dupp' a short and due to closure of semi lunar valves.
- **29.** (a) Pace maker (SA node) which lies in the wall of the right atrium near the opening of the superior vena cava.
- **35.** (e) Open circulatory system occurs in invertebrate animals such as arthropods (e.g. insects, spiders, crabs and lobsters) and some molluscs (e.g. snails, oysters and clams).
- 42. (b) Sinus venosus is the first chamber of the heart in fish, amphibia and reptiles. In fish it receives blood from the cuverian ducts and hepatic veins and leads into the single auricle. In amphibians and reptiles it receives blood from the three venae cavae and leads to the right auricle. Birds and mammals have no sinus venosus.
- (c) 'Bundle of His' is a part of conducting system of human heart.
- 46. (d) The AV valves close due to sharp rise of intraventricular pressure, their closure produces first heart sound LUBB.

- 47. (c) When irregularity in the heart rhythm occurs, normal heart rhythm can be restored and maintained by surgically implanting an artificial pace maker, a device that sends out small electrical current to stimulate the heart to contract.
- 52. (d) Spiral valve is a valve present in truncus arteriosus of amphibian heart guiding flow of different type of blood in three aortic arches.
- **56.** (b) *Pleura* is a membrane in which the lungs of a vertebrate are suspended from the wall of the throax *i.e.*, it is the covering of the lungs.
- **57.** (d) AV–node delays the impulse of contraction before transmitting it to the ventricles. Thus sets the time interval between the contraction of auricles and ventricles.
- **59.** (c) Cardiac output=stroke volume×venticular systole/minute = 70 ml × 72 (min) = 5040 ml/min = about 5.5 litres.
- 60. (a) Alary muscles are a pair of triangular fan like muscles in the floor of pericardial sinus of cockroach. The respiratory movements of abdomen and contraction of alary muscles increase the pumping force of the cockroach's heart.
- **62.** (d) The wall of ventricles are thicker then those of auricles. Thickest wall is found in the left ventricle.
- **66.** (d) The wall of heart has three layer : epicardium, myocardium and endocardium.
- **68.** (a) Cardiac impulse (Heart beat) normally originate from the pace maker (S.A. node).
- **69.** (a) In earthworm, an annelid, 4 pairs of thick, muscular, pulsatile hearts are present.
- (c) Capillary has no muscular wall. Its wall is made of a single layer of endothelial cell.
- 75. (b) Inferior vena cava (post caval) collect blood form lower part of trunk and hind limbs.
- **76.** (c) Superior vena cava (pre caval) collect blood from head, fore limbs and upper part of chest.
- **80.** (a) In the right atrium adjoining the internal septum, an oval depression the fossa ovalis.
- **81.** (c) Bundle of His is a network of muscle fibres found in between two ventricles.
- 82. (b) Veins bring blood from the body to the heart.
- **84.** (d) Right auricle receives deoxygenated blood from the body via sinus venosus in the lower vertebrates.
- **86.** (b) Atherosclerosis is narrowing of arteries and arterioles due to deposition of fats on their lining.
- **87.** (a) During auricular systole, the auricles contract and drain most of their blood into the respective ventricles.
- 89. (a) Transmission of impulse occurs as S-A node→A-V node→Bundle of His→Purkinje system.
- **91.** (b) Since the impulse originates in the heart it self by a patch of modified heart muscle without requiring any external stimulation.
- **92.** (d) Thoracic duct is a dorsal longitudinal lymphatic vessel which begins below diaphragm, ascends in front of vertebral column and drains into innominate vein at the base of neck
- 96. (b) In the given diagram 'D' represent the vena cava. Vena cava is either of the two large veins that carry deoxygenated blood into the right atrium.

UNIVERSAL BOOK DEPOT 1960

Blood vessel

- 2. (d) Because serotonin is a vaso-constrictor.
- **4.** (a) Pulse can be detected in superficial artery like radial artery of wrist and temporal artery.
- (b) A pair of phrenic arteries arise from the aorta and supply the diaphragm. Phrenic artery present in human but absent in frog.
- (b) Blocking of arteries due to deposition of fat and calcium is called Atherosclerosis. Emphysema is a chronic obstructive lung disease.
- 10. (d) In the region behind 13^{th} segment, blood laden with digested nutrients and O_2 is collected in the dorsal vessel while in anterior region of body, some of this blood is supplied by dorsal vessel to various parts.
- (c) Arteries are best defined as vessels which carry blood away from the heart to different organs.
- (c) Intravenous injection is given for rapid distribution of drugs/substance. Intramuscular injection is given for producing local effect.
- (d) Least concentration of urea is found in renal vein. This is because urea is excreted through urine formed in kidney.

Blood pressure, ECG

- (c) Blood pressure is measured in mm of mercury by an instrument known as sphygmomanometer. The instrument was invented by an Italian Doctor Riva-Rocci in 1896.
- (b) ECG is the record of changes in electrical potential of heart during one beat.
- 5. (a) It is also called ventricular complex.
- (b) Upon systole of left ventricle blood is pushed in aorta, which creates systolic blood pressure which is 120 mm Hg.
- 12. (d) With the increase in intra cranial pressure, the cerebral blood flow is reduced. This increased pressure also stimulates the vasomotor centre and increases systemic blood pressure.
- (a) Hypertension occurs if the blood pressure is 190/110.
 This can harm the vital organ like brain and kidneys.
- 15. (c) Systole is the muscular contraction of the heart or of any chamber of it. Commonly, it is used to refer to the ventricles of human heart. During this stage the openings for CSA and PT are open, so the blood leaves the ventricles.
- (a) Blood is diverted towards alimentary canal. Therefore the pressure of blood falls in brain.
- 21. (b) Except ANF which is released by Wall of atrium, rest three increase blood pressure and GFR by various methods. ANF will further decrease blood pressure.

Lymphatic system

2. (d) Essentially all the lymph from the lower part of the body even most of that from the legs flows up the thoracic duct and empties into the venous system at the juncture of left internal jugular vein and subclavian vein.

- (c) Colour of blood is due to presence of haemoglobin in RBCs since RBCs are absent in lymph so lymph is colourless.
- 4. (b) Old RBCs are destroyed along with pathogens by phagocytosis carried out by macrophages. Thus, spleen acts as graveyard of RBCs.
- (a) An antibody is a molecule that specifically inactivates an antigen.
- (b) Antigen are present on cell surface and cause the formation of antibodies specifically reacting with them.
- (d) So spleen is also called the blood reservoir of human body.
- (b) Haemopoietic stem cells differentiate into T-and Blymphocytes in the bone marrow T- cells then migrate to thymus gland for their proliferation.
- 16. (a) Humoral or Antibody mediated immune system is formed or proteinous defensive chemicals called antibodies which are produce by B lymphocyte and circulate in the plasma of blood and lymph and protect the body from bacteria and virus.
- **17.** (a) Surgical removal of thymus gland of new born shall result in the failure to produce *T* lymphocytes.
- (c) Lymphatic vessels unite to form two main vessels called thoracic duct and right lymphatic duct.

Portal system

- (a) Hepatic portal system starts from digestive system and finishes in liver.
- (c) Hepatic portal vein in Rabbit starts with capillaries and ends in capillaries.
- (a) Blood circulation that starts in capillaries and ends in capillaries is called portal circulation.
- (b) Hepatic portal vein carries blood rich in absorbed food material such as glucose and amino acid from intestine to liver.
- (d) Renal portal system is found in frog in which femoral, sciatic and renal portal veins are include.

Critical Thinking Questions

- (a) Blood of cockroach lacks respiratory pigment. Hence,
 O₂ is carried by the respiratory tubules.
- 2. (c) Vein contain valves to prevent back flow of blood.
- 4. (b) Because in vein presence of CO_2 decreases the pH.
- (b) Largest blood vessel in the body is carotid systemic or dorsal aorta, It is a question marked shaped long vessel, that arise from left ventricle of the heart.
- (a) Angina is due to reduced blood supply to heart wall.
 Person with blood group AB is universal recepient.
- 10. (a) In haemoglbin iron is present in ferrous (Fe⁺⁺) state.
- 12. (c) During ventricular systole. The pressure increases in the ventricles, thus forcing the oxygenated blood from left ventricle into systemic aorta and deoxygenated blood from right ventricle into pulmonary aorta.
- (c) Stimulation of vagus nerve decreases the heart rate but its continuous stimulation shows no further decrease.

- 15. (d) Under the normal conditions heart rate has an inverse relation with the size of the animal.
- 16. (b) Whale is a mammal and has 4 chambered heart with 2 atria and 2 ventricles, oxygenated and deoxygenated blood flow on separate sides.
- (d) Because pace maker of the heart is capable of initiating and regulating the heart beat.
- 18. (b) To allow relatively quick saturation and dissaturation with O_2 and CO_2 .
- 19. (d) Systole refers to contraction of atria (atrial systole) which propels blood into ventricles and contraction of ventricles (ventricular systole) expels blood into aorta and pulmonary artery.
- 21. (a) Macrophages of spleen engulf and destroy wornout blood corpuscles, dead and live pathogens, cell Lebris, Pigment gramules and other useless particulate materials, thus regularly cleaning the blood of its impurities.

Assertion and reason

- 1. (b) The valves present in heart when pushed by blood in the right direction, the flaps of the valve swing apart and allow the blood to flow through, but when pushed in the opposite direction, the flaps close sharply to block the passage through the valve. Thus these valves resemble swing doors in action. Hence the valves of the heart maintain unidirectional flow of blood and prevent it's regurgitation in the opposite direction.
- 2. (b) During the wound, germs are removed by the process of phagocytosis by WBC. WBCs accumulate at the site of wound by diapedesis. It is the squeezing of leucocytes out from the endothelium of capillaries to fight against foreign agent.
- (c) Saline water is not given to a patient of hypertension because it may cause rise in blood pressure which may be fatal to patient.
- 4. (d) As the cardiac impulse spreads over the cardiac chambers and causes their contractions, electrical changes sweep over the cardiac chambers in a specific sequence. These changes in the electrical potential over the heart can be recorded by fixing leads on two arms, the left leg and the chest, and connecting them to an apparatus called electrocardiograph. The record is called electrocardiogram (ECG). An electrocardiogram is the recording of the various events of the cardiac cycle. Defects in cardiac functions or structures are reflected in changes in the pattern of electrical potentials recorded in the ECG. The ECG is, therefore of immense diagnostic value in cardiac diseases. On the other hand, EEG is an index of the brain functions. electroencephalogram represents or spontaneous electrical activity of the brain as recorded from the electrodes placed on the scalp. EEG wave pattern obtained shows certain characterstic features of the brain like the frequency amplitude of the signals of brain. Thus any deviation from the normal caused either by brain disease or change in the physiological state of the brain can be easily detected by EEG.

- (a) An artificial pacemaker is a therapeutic instrument which 5. is implanted in the heart of patients to generate the heart beat. A pacemaker is used when the normal heart rate of 72-80 drops down to abnormally low levels like 30-40 due to diseases or operations and threatens the life of the patient. Sometime, the SA node may become damaged or defective. It then fails to generate cardiac impulses at the normal rate. The heart beats become abnormally slow and irregular, and ventricles fail to pump the required amount of blood. This is remedied by the surgical grafting of artificial pacemaker instrument in the chest of the patient. The artificial pacemaker stimulates the heart electrically at regular intervals to maintain its beats. Thus it replaces the SA node as the originator of the cardiac impulse.
- 6. (a) ECG consists of P-wave, QRS wave and T-wave. ECG gives important information concerning the spread of excitation to the different parts of heart and in the diagnosis of abnormal cardiac rhythm and myocardial damage.
- 7. (b) Blood pressure is the arterial blood pressure taken in left brachial artery and the instrument used to measure blood pressure is sphygmomanometer.
- 8. (a) The heart is a pumping organ for blood circulation which consists of chambers communicating with each other. In fishes the heart is two-chambered, consisting of an auricle and a ventricle. An accessory chamber called sinus venosus is also present which serves as a reservoir and opens anteriorly into auricle through the sino atrial aperture. Fish heart contains and pumps only deoxygenated blood because after getting oxygenated from gills, the blood doesn't return back to the heart. Instead, it is supplied directly to the various parts of the body.
- 9. (c) Lacunae and sinuses are the open spaces and channels present in the tissues of prawn. Prawn possesses a heart which pumps the oxygenated blood into some arteries. These arteries directly open into the lacunae and sinuses. The tissues are thus in direct contact with blood. A sufficiently high blood pressure, however, cannot be maintained in the open lacunae and sinuses inspite of the pumping action of the heart. So, blood flows at a very slow velocity in the lacunae and sinuses.
- 10. (e) SA node and AV node are the contraction node. SA node possess the highest rhythmicity among all cardiac muscle fibres and can initiate excitory wave at highest rate.

FT Self Evaluation Test

- 1. Lack of pulmonary surfactant produces [AMU (Med.) 2009]

 - (b) Emphysema
 - (c) Cystic fibrosis

- 2. (a) Myogenic heart is found in molluscs and vertebrates.
- (b) The blood is composed of a faintly yellow transparent fluid known as the plasma and floating in this fluid are numerous cells or corpuscles of different kinds. Thus

Blood -Blood cells = Plasma.

- (c) Adrenaline increases the heart beat normally during active and stress conditions.
- (c) Four chambered heart is found only in mammals and birds except some reptiles such as crocodiles, gavialis and alligators.
- (a) The general distribution of the femoral arteries is to the lower abdominal wall, groin, external genitals and muscles of the dorsal part of the thigh.
- 11. (a) Its due to buffer action of blood.
- 12. (a) Chordae tendinae are numerous, strong inelastic thread like tendons present in the ventricles of the mammalian heart.
- (b) Arteries are thick walled, carrying oxygenated blood from heart to various parts of body at high pressure.
- 14. (b) The first human heart transplant was performed on 3rd December, 1967 by a team of 30 doctors headed by Prof. Christian Barnard on 55 years old Louis Washkansky at the Groote Schurr Hospital, Cape Town, South Africa. Inspite of the operation by a leading surgeon Washkansky died on 21st December, 1967.
- 16. (a) Neurogenic heart stops beating on cutting nerve supply.
- (a) The bicuspid valve between the left atrium and the left ventricle of mammalian heart is known as mitral valve.
- (c) In a normal human being, the systolic and diastolic blood pressures are respectively 120 mm Hg and 80 mm Hg.

The component structural and functional units of the bodies of all organism are cells which have been looked as "miniature chemical factories" because of continuous metabolism taking place in these. It yields certain waste products which are, not only useless, but harmful to the cells and the body. Cells, therefore, throw out these wastes, by diffusion, into their surrounding medium. Finally, these wastes are eliminated by the body into its external environment. This is, thus an important vital activity of all organism. It is called excretion.

Excretory organs of different organism

- (1) Protozoans: In protozoans like Amoeba and Paramecium carbon dioxide and ammonia are mostly excreted out by diffusion through general body surface. It is considered that the contractile vacuoles also play some role in the removal of excretory products.
- (2) Sponges: In sponges, the nitrogenous metabolic waste (ammonia) leaves the body in the outgoing water current by diffusion.

Most of the sponges are marine and have no problem of surplus water in their cells. A few sponges lie in hypotonic fresh water and have contractile vacuoles in most of their cells.

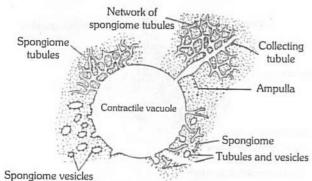

Fig: 5.4-1 Contractile vacuole in sponge

- (3) **Coelenterates**: Hydra also lacks special excretory organs. The nitrogenous waste products like ammonia are removed through the general surface of the body by diffusion. Some nitrogenous waste products are also thrown along with indigestible matter through the mouth.
- (4) Platyhelminthes: Planaria, liverfluke and tapeworm possess a large number of excretory cells called the flame cells (solenocytes) or protonephridia and long excretory ducts (also called canals of vessels). The flame cells open into the ductules which in turn open into the excretory duct.

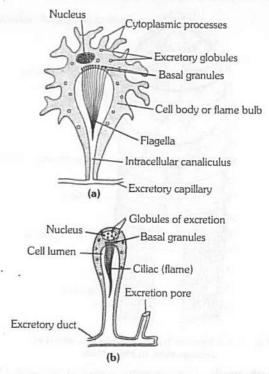

Fig: 5.4-2 Flame cell (a) Fasciola (b) Planaria

(5) **Nematoda:** The round worms such as Ascaris have H-shaped excretory system. It is made up of a single Renette cell, in entire length of body. It consists of two longitudinal excretory canals connected anteriorly by a network of transverse canals. A short terminal duct opens outside via excretory pore. Ascaris excretes both ammonia and urea.

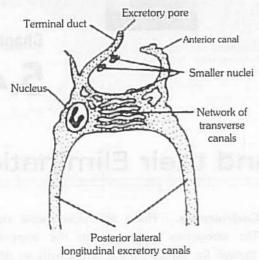

Fig: 5.4-3 Renette cell of Ascaris

(6) Annelids (Earthworm): In earthworm excretory system is known as nephridial system, which consist of 3 types of nephridia pharyngeal, septal, and integumentary nephridia. All nephridia commonly called micronephridia. Earthworm excrete 40% urea, 20% ammonia, 40% amino acids. Earthworm is mainly ureotelic. Chloragogen cells found in coelomic fluid are also excretory in nature. Blood gland in earthworm found in 4, 5, 6 segment, serves for excretion, manufacture of blood corpuscles and Hb.

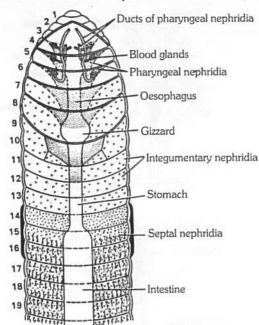

Fig : 5.4-4 Various types of nephridia and their arrangement in Pheretima

(7) Arthropods: The excretory system of the adult Prawn (crustacean) consists of a pair of antennary or green glands, a pair of lateral ducts and a single renal sac. Insects, centipedes, millipedes and arachnids like scorpion and spider posses Malpighian tubules as their principal excretory organs. In the Malpighian tubules bicarbonates of potassium and sodium, water and uric acid are formed. A large amount of water and bicarbonates of potassium and sodium are reabsorbed by the cells of Malpighian tubules and then transferred to the blood (haemolymph). Uric acid is carried to the alimentary canal of the insect and is finally passed out through anus. Spiders and scorpions possess Malpighian tubules and coxal glands both for excretion.

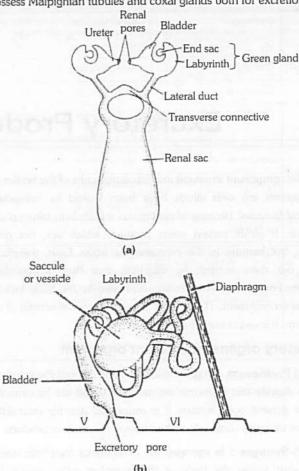

Fig: 5.4-5 (a) Antennary gland of Prawn (b) Coxal gland of Scorpion

(8) Molluscs: They have one or two pairs of kidneys or organs of bojanus and keber's organ for excretion in unio.

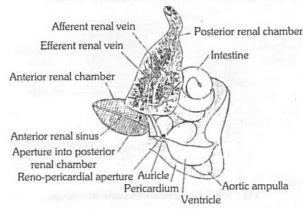

Fig: 5.4-6 Organ of Bojanus (Pila - mollusca)

(9) **Echinoderms**: Specialized excretory organs are absent in echinoderms (e.g., Starfish). The excretory products, chiefly ammonia, urea, and creatinine are eliminated by diffusion through

dermal branchiae (primitive gills) and tube feet. Amoeboid coelomocytes also excretory.

Table: 5.4-1 Excretory organs of different organisms

S.No.	Phylum	Excretory/osmoregulatory Organ/Organelle and	Function	Example
1.1		principal N ₂ -waste	abos biinii kw is give.	
I. Inverte	ebrates	Market Market State State Congress		Militaria malantina
(1)	Protozoa	Contractile vacuole	Ammonotelic	Amoeba
(2)	Porifera	Ammonia	Osmoregulatory	Paramecium
	1	General surface of body	Ammonotelic	Sycon, Leucon
(3)	Coelenterata	Ammonia, General surface of body	Ammonotelic	Hydra
(4)	Platyhelminthes	flame cells (=Solenocytes) form the protonephridial system	Ammonotelic	Taenia, fasciola, planaria
(5)	Nematoda	H-shaped excretory organ, Renette cells	Ammonotelic	Ascaris
(6)	Annelida	Nephridial system, (Metameric), various types	Ammonotelic	Pheretima
(7)	Arthropoda			
a.	Class-Insecta	Malpighian tubula Nanhasanta III		
Tensing molting		Malpighian tubule, Nephrocyte, Uricose gland (Uric acid)	Uricotelic	Periplaneta, House fly, mosquito
b.	Class Crustacea	Antennary (=green) gland, Hepatopancreas Uric acid	Uricotelic	Palaemon
c.	Class Arachnida	Coxal glands, Malpighian tubule, Hepatopancreas, Nephrocytes	Uricotelic, Guanine and Xanthine in small amount	Spider, Scorpion
8)	Mollusca	(a) Kidneys or organs of Bojanus	Guanine	Unio
		(b) Keber's organ	Guanine	Unio
	testing L	(c) Renal organs	Ammonotelic in aquatic, & uricotelic in terrestrial

		(d) Renal papilla		
		(e) Hatschek nephridia	THE PARTY IN	

Excretory products in different organisms

(1) Waste products of protein metabolism

- (i) Amino acids: These are end products of protein digestion absorbed into the blood from small intestine. Certain invertebrates, like some molluscs (eg Unio, Limnae, etc.) and some echinoderms (eg Asterias) excrete excess amino acids as such. This is called aminotelic excretion or aminotelism.
- (ii) **Ammonia** $(NH_4^+ \text{ or } NH_3)$: In most animals, excess amino acids are deaminated, i.e. degraded into their keto and ammonia groups. The keto groups are used in catabolism for producing ATP, whereas ammonia is excreted as such or in other forms. Ammonia is highly toxic and highly soluble in water. Its excretion as such, therefore, requires a large amount of water. That is why, most of the aquatic arthropods, bony and freshwater fishes, amphibian tadpoles, turtles, etc excrete ammonia. This type of excretion is called ammonotelic excretion or ammonotelism.
- (iii) **Urea** $CO(NH_2)_2$: This is less toxic and less soluble in water than ammonia. Hence, it can stay for some time in the body. Many land vertebrates (adult amphibians, mammals) and such aquatic animals which cannot afford to lose much water (e.g. elasmobranch fishes) marine bony fish, adult frog, earthworms, nematodes, turn their ammonia into urea for excretion. This type of excretion is called ureotelic excretion or ureotelism.
- (iv) **Uric acid**: Animals living in dry conditions, such as land gastropods, most insects, land reptiles (snakes and lizards), birds and Kangaroo rat (mammal) *etc* have to conserve water in their bodies. These, therefore, systhesize crystals of uric acid from their ammonia. For the formation of uric acid xanthine oxidase enzyme is necessary. Uric acid crystals are nontoxic and almost insoluble in water. Hence, these can be retained in the body for a considerable time before being discharged from the body. Uric acid is the main nitrogenous excretory product discharged in solid form. This excretion is called uricotelic excretion or uricotelism.
- (v) **Trimethylamine oxide**: Certain marine molluscs, crustaceans and teleost fishes first form trimethylamine from their ammonia by a process known as methylation. Then, the trimethylamine is oxidised to trimethylamine oxide for excretion. This oxide is soluble in water, but nontoxic.
- (vi) Guanine: Spiders typically excrete their ammonia in the form of guanine. Some guanine is also formed in unio, penguin, birds and it is insoluble in water. Hence, no water is required for its excretion.

(2) Waste products of nucleic acid metabolism

As a result of nucleic acid digestion, nitrogenous organic bases – purines (adenine and guanine) and pyrimidines (cytosine, thymine and uracil) – are absorbed from intestine into the blood. Most of these are excreted out. About 5% of the total excretion of body accounts for these substances. In man, purines are changed to uric acid for excretion. In most other mammals, nitrogenous organic bases are excreted in the form of allantoin. Insects, amphibians, reptiles and birds also excrete these bases in the form of uric acid. Some freshwater molluscs and crustacean arthropods excrete these in the form of ammonia.

- (3) Some sundry excretory substances (Others excretory products)
- (i) Hippuric and ornithuric acids: Sometimes food of rabbit and other mammals may contain traces of benzoic acid, or this acid may be formed in small amounts during fat metabolism. It is highly toxic. As it is absorbed in blood, it is combined with glycine and changed into less toxic hippuric acid for excretion. In birds, benzoic acid is combined with ornithine and changed into ornithuric acid for excretion.
- (ii) Creatine and creatinine: Muscle cells contain molecules of creatine phosphate, which are high energy molecules and serve for storage of bioenergy like ATP. It is synthesised by 3 amino acids (G.A.M.) (Glycine, Argenine and Methionine). Excess amount of this phosphate is, however, excreted out as such, or after being changed into creatinine.

Excretory system of man

Mammalian (human) urinary system consists of a pair of kidneys, a pair of ureter, a urinary bladder and a urethra.

(1) **Kidneys**: The kidneys are dark-red, bean-shaped organs about 11 cm long, 5 cm wide and 3 cm thick, each weight about 150 gm in an adult male and about 135 gm in adult female. They are placed against the back wall of the abdominal cavity just below the diaphragm, one on either side opposite the last thoracic and first three lumbar vertebrae. The 11th and 12th pairs of ribs protect them.

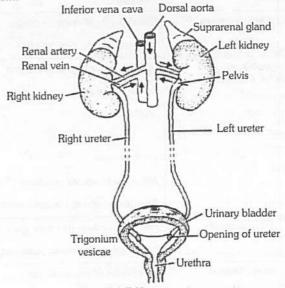

Fig: 5.4-7 Human urinary system

The kidneys are covered by peritoneum on the front (ventral) side only. thus, they are retroperitoneal. The right kidney is attached more anterior than the left in rabbit. This asymmetry is just the reverse of that found in man.

In man left kidney occurs at a slightly higher level than the right one, because right side has prominent right liver lobe. In rabbit the condition is little differ due to quadropedilism *i.e.* left kidney is in normal position while the right kidney shift ahead to provide place for stomach below it.

In mammals, the kidney is concavo convex. The center of concave inner surface is called as hilum or hilus which gives out a ureter. From this hilus surface the renal artery enters into the kidney, the renal vein comes out and the renal nerves enter into the kidney.

- (i) **Structure of kidney:** The kidneys are metanephric in mammals. The kidney is divisible into two parts outer-cortex and inner-medulla. Three layers of tissue surround each kidney.
- (a) The innermost, renal capsule made up of fibrous connective tissue.
 - (b) The intermediate layer, adipose capsule of fatty tissue.
 - (c) The outermost, renal fascia of dense connective tissue.

Renal pyramids or medullary pyramids: The medulla is subdivided into 8 to 18 conical masses – the renal pyramid, each having broad base towards the cortex and a narrow end called renal papilla towards the pelvis.

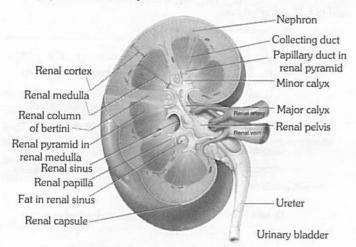

Fig: 5.4-8 L.S. of human kidney

Path of urinary drainage : Collecting duct \rightarrow Papillary duct in renal pyramid \rightarrow Minor calyx \rightarrow Major calyx \rightarrow Renal pelvis \rightarrow Ureter \rightarrow Urinary bladder

Renal columns of bertini: Between the pyramids, the cortex extends into the medulla or renal columns of bertini.

Calyx: Each renal papilla projects into the cavity of a minor calyx, minor calyx join to form major calyx. The major calyx open into a wide funnel like structure, the pelvis. The latter leads into the ureter. In rabbit, the pelvis is unbranched hence, it is without calyx.

In frog ventral surface of each kidney has many ciliated funnels called nephrostomes. They drain wastes from body cavity (coelom) and connect to renal veins in frog or to uriniferous tubules in tadpoles.

(ii) Histology of kidney: Histologically a kidney is made of innumerable thin, long, much convoluted tubular units called uriniferous tubule or nephron.

Nephron is the structural and functional unit of kidney. One human kidney may contain about one million (10 lac nephron) nephron (In rabbit each kidney bear about 2 lac nephron). In frog each kidney bears about 2 thousand nephron.

(a) Structure of nephron : A nephron or uriniferous tubules consist of two parts : **Malpighian body** / **Renal Corpuscles**: The proximal end of each nephron forms a blind or closed, enlarged and double walled cup, the Bowman's capsules in the cortex. (name Bowman's capsule is based on English physiologist and histologist William Bowman).

Each capsule contains a network of blood capillaries the glomerulus which receives blood through afferent arteriole and the blood comes out through the efferent arteriole . The diameter of the efferent arteriole is comparatively lesser. Bowman's capsule and glomerulus receives about 20-25% of the cardiac out put (blood) at rest.

The composite structure of Bowman's capsule and glomerulus is known as Malpighian body or Malpighian corpuscles after the Italian microscopist Marcello Malpighi.

Tubule : The tubule is differentiated into 3 parts P.C.T., Henle's loop and D.C.T.

The Bowman's capsule opens into a proximal convoluted tubule (P.C.T.) the anterior part of the P.C.T. is more coiled where as its posterior part is almost straight. The P.C.T. opens into a Henle's loop. The Henle's loop is a U- shaped structure or makes hair pin turn, which has a distinct descending limb and an ascending limb. The ascending limb opens into the distal convoluted tubule. The D.C.T. is a coiled structure. Many D.C.T. unite to form a collecting duct. The collecting ducts of one pyramid unite to form a duct of Bellini. The duct of Bellini lead into the pelvis part.

(b) Arrangement of nephron: The malpighian body and most of the P.C.T. and D.C.T. are situated in the cortex. Henle's loop and collecting ducts are found in the medulla.

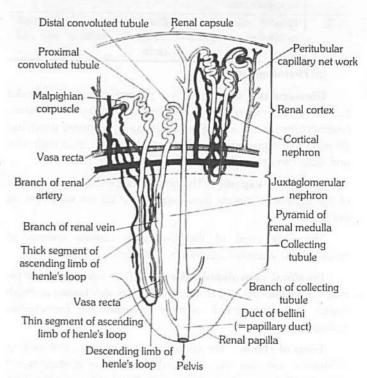

Fig: 5.4-9 Position, structure and blood supply of cortical and juxtamedullary nephrons in a mammalian kidney

Vasa recta: The efferent arteriole of juxta-glomerular nephron forms a peritubular capillary system around the Henle's loop which is called vasa recta. Each of the vasa recta makes U turn at the inner most part of the medulla and return to the venous circulation near the junction of medulla and cortex. The efferent arteriole and peritubular capillaries technically constitute a renal portal system. All amniotes as reptiles, birds and mammals have this renal portal system of efferent arteriole and peritubular capillaries.

(c) **Types of nephron :** Nephrons are of two types cortical and juxtamedullary, with regard to their location in the kidney. The cortical nephrons form about 80% to 85% of total nephron.

Remaining 15 - 20% are juxta medullary nephron.

Table: 5.4-2 Differences between cortical and Juxtamedullary nephrons

S.No.	Cortical Nephrons	Juxtamedullary Nephron
1.	Form 80 – 85% of total nephrons.	Form only 15 – 20% of total nephrons.
2	Are small in size.	Are large in size.
3.	Lie mainly in the renal cortex.	Have Bowman's capsules in the cortex near its junction with the medulla.
4	Henle's loops are very short and extend only a little into the medulla	Henle's loop are very long and extend deep into the medulla.
5.	Control plasma volume when water supply is normal.	Control plasma volume when water supply is short.
6.	Glomeruli in superficial region of cortex	Glomeruli deep in cortex
7.	Blood supply from peritubular capillaries only.	Blood supply from both peritubular capillaries, and vasa recta.

(d) Histology of nephron

Glomerulus : Glomerulus is a network of upto 50 parallel branching and anastomosing capillaries covered by endothelium, basement membrane and epithelium made of podocytes which has slit pores that restrict passage of colloids. However, small molecules and water can easily pass through them into the P.C.T.

Bowman's capsule : The podocytes forming the inner wall of the Bowman's capsule have gaps (about 25 *nm* wide) the slit pores.

The outer wall of the Bowman's capsule consists of unspecialized squamous epithelium (flattened).

Proximal convoluted tube : P.C.T. is made up of simple cuboidal epithelium . It has microvilli so it is also known as brush border epithelium. P.C.T. is most important site for selective reabsorption.

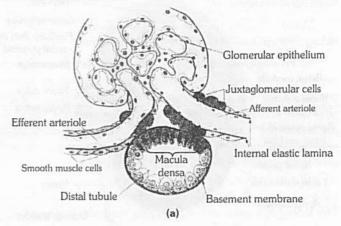

Loop of Henle: The epithelium of descending limb of loop of Henle is very thin and composed of squamous epithelium and ascending limb is made up of two parts. First is thin ascending limb lined by squamous epithelium and second thick ascending limb

lined by cuboidal epithelium. The ascending limb is impermeable to water and permeable to NaCl.

Distal convoluted tube : D.C.T. is made up of cuboidal epithelium which is glandular in nature.

Collecting ducts: The collecting ducts are lined by cuboidal epithelium in different regions. At intervals, the cuboidal cells are ciliated.

Juxta-glomerular apparatus : This specialized cellular apparatus is located where the distal convoluted tubule passes close to the Bowman's capsule and afferent arteriole, Cells of the D.C.T. epithelium in contact with afferent arteriole are denser than other epithelial cells known as maculla densa. Maculla densa has special Lacis cell or Polkisson's cell. These cells secrete renin hormone that modulate blood pressure and thus renal blood flow and G.F.R. are regulated.

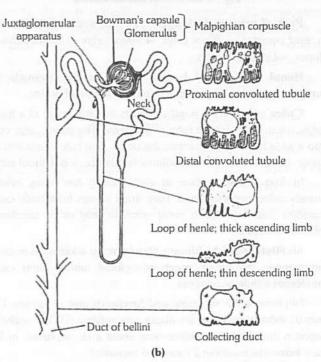

Fig: 5.4-10 (a) Juxta glomerular apparatus (b) Juxtamedullary nephron and epithelial cells in the wall of its various parts

Origin and types of kidneys in different vertebrate

Kidney tubules (nephrons) arise in the embryo in a linear series from a special part of mesoderm called mesomere or nephrotome.

Number, complexity and arrangement of nephrons differ in different groups of vertebrates. A nephron is differentiated into three parts – peritoneal funnel, tubule and malpighian body. Peritoneal funnel (nephrostome) are normally present in embryos and larvae and considered as vestigeal organ of hypothetical primitive kidneys.

(1) **Archeonephros kidney:** Archeonephros is the name given to the hypothetical primitive kidney of ancestral vertebrate. It is also called as holonephros or complete kidney. (It extended entire length of coelom) Its tubules are segmentally arragned and nephrostome is present. Glomerulus is external (without capsule). Its duct is called as archeonephric duct. *e.g.*, Larva of myxine and some apodan amphibians.

Modern vertebrates exhibits three different kinds of adult kidney Pronephros, Mesonephros and Metanephros.

- (i) **Pronephros:** It originates from the anterior part of the nephrotome. It is also termed head kidney due to its anterior position. There are only 3 pronephrine tubule (nephron) in frog embryo, 7 in human embryo, and about 12 in chick embryo which are segmentary arranged. Nephrostome is present, glomerulus is external and unite to form glomus in some cases. Duct is pronephric duct or mullerian duct. A pair of pronephros appear in all vertebrate embryos but they becomes functional kidneys in adult myxine and embryos of all anamniotes (fish, amphibian). This kidney is found as transitory kidney in all vertebrates embryos.
- (ii) **Mesonephros:** It originates from the middle part of the nephrotome. Duct is mesonephric or Wolffian duct. Nephrostome is absent except some embryos of anamniotes. Example In amniotes (reptiles, birds and mammals) mesonephros is functional only in the embryos, replaced by metanephros in the adult. In anamniotes (fishes and amphibian) mesonephros is functional in both embryo as well as adults. Also found in adult petromyzon.
- ☐ In fish and amphibians, tubules extend through length of coelom behind pronephros and formed from entire nephrotome left behind the pronephrus called opisthonephric kidney. The opisthonephric kidney specially in males is differentiated into anterior genital and post renal part.
- \square In frog mesonephric duct is also known as Bidder's canal which carry sperm and urine both.
- (iii) **Metanephros**: It originates from the posterior part of the nephrotome. When metanephric tubules develop, all the mesonephric tubules disappear except those associated with the testes in male and forming vasa efferentia. Nephrostome absent. A thin, U-shaped loop of Henle forms between P.C.T. and D.C.T. which is incomplete in Reptiles and Birds and well developed in mammals. Duct is metanephric or ureter. Reproductive duct is separate. The kidney is highly compact which possesses innumerable nephrons. Example All amniotes Reptile, Birds and mammal.

- (2) **Ureters**: From the hilum of each kidney emerges a whitish tube the ureter. The ureters are about 28 cm long. Their wall consists of transitional epithelium surrounded by a layer of muscle fibres. Openings of the two ureters in the bladder are separate, but closely placed. These are oblique, so that the urine cannot regurgitate into the ureters when the bladder contracts. Peristalsis of ureters also checks regurgitation of urine. Like kidneys, the ureters are retroperitoneal.
- (3) Urinary bladder and Urethra: The urinary bladder is pear-shaped hollow muscular organ situated in pelvic cavity, which is made up of smooth and involuntary muscles. The muscles are also known as detrusor muscles (muscles that has the action of expelling a substance). The lower part or neck of the bladder leads into the urethra. There is a smooth triangular area, called trigonium vesicae. The lumen of the urinary bladder is lined by transitional epithelium which has great power of stretching. The neck of bladder is guarded by two sphincters, inner is involuntary controlled by spinal reflex and outer is voluntary controlled by cerebral cortex. A person feels the sensation of micturition when the quantity of urine in the bladder is about 300 c.c. The average capacity of urinary bladder is 700 - 800 ml. In general, urinary bladder capacity is smaller in females because the uterus occupies the space just superior to bladder. Mucosa of bladder with folds called rugae. (rugae also present is stomach and vagina).

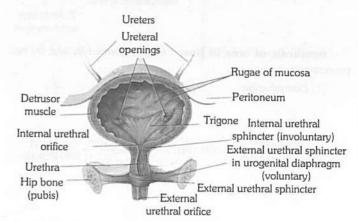

Fig: 5.4-11 Parts of ureters, trigone of the bladder, sphincters and urethra

(4) **Urethra**: The urinary bladder leads into the urethra. In female, it is quite short, only about 3 to 5 cm long, and carries only urine. It opens by urethral orifice, or urinary aperture in the vulva infront of the vaginal or genital aperture. In a male urethra is much longer, about 20 cm and carries urine as well as spermatic fluid. It passes through the prostate gland and the penis. It opens out at the tip of the penis by urinogenital aperture. In males the epithelium of spongy urethra is stratified or pseudostratified columnar epithelia, except near external urethral orifice, which is non keratinized stratified squamous epithelia. The prostatic urethra is lined by transitional epithelia, while membranous urethra is lined by pseudostratified columnar.

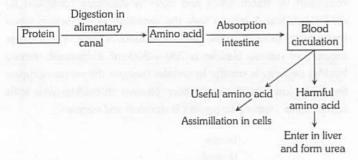

Table: 5.4-3 Differences between male and female urethra

S. No.	Male urethra	Female urethra
1.	It is about 20 cm long.	It is just 3 – 5 cm long.
2.	It has 3 regions : prostatic urethra (3-4 cm), membranous (1 cm) and penile (15 cm)	It is not differentiated into regions.
3.	It opens out at the tip of the penis by urinogenital aperture.	It opens into the vulva by urinary aperture.
4.	It carries urine as well as semen to the exterior.	It carries only urine to the exterior.
5.	It has 2 sphincters.	It has a single sphincter.

Physiology of excretion

Major nitrogenous excretory substance in frog, rabbit and human is urea, i.e. these are ureotelic animals. The excretory physiology in these animals may be considered under two phases, viz urea synthesis and formation and excretion of urine.

Synthesis of urea in liver : Urea is formed in liver by two processes.

(1) Deamination

(2) Ornithine cycle

(1) **Deamination :** The amino acid is oxidised using oxygen. This results in removal of the amino group (NH_2) and leaves pyruvic acid. The pyruvic acid can enter the Krebs cycle and be used as a source of energy in cell respiration. The amino group is converted to ammonia (NH_3) during deamination. Deamination is also known as oxidative deamination.

$$\begin{array}{ccc} CH_3 & CH_3 \\ | & | \\ CH-NH_2+\frac{1}{2}O_2 & \longrightarrow CO+NH_3 \\ | & | \\ COOH & COOH \\ \text{(Amino acid)} & \text{(Pyruvic acid)} \end{array}$$

With the help of a number of enzymes and energy of A.T.P. two molecules of ammonia are combined with CO_2 to form urea according to the ornithine cycle.

(2) Ornithine cycle (Kreb-Henseleit cycle): In liver one molecule of CO_2 is activated by biotin and combines with two molecules of NH_3 in the presence of carbamyl phosphate synthatase enzyme (C.P.S.) and 2 ATP to form carbamyl phosphate and one molecule of H_2O is released. Carbamyl phosphate react with ornithine and form citrulline. Citrulline combines with another molecule of ammonia and form arginine. Arginine is broken into urea and ornithine in the presence of an enzyme arginase and water.

$$2NH_3 + CO_2 \xrightarrow{\text{Arginase}} NH_2 - CO - NH_2 + H_2O$$

Liver cells, thus, continuously remove ammonia and some CO_2 from blood and release urea into the blood. Kidneys continuously remove urea from the blood to excrete it in urine.

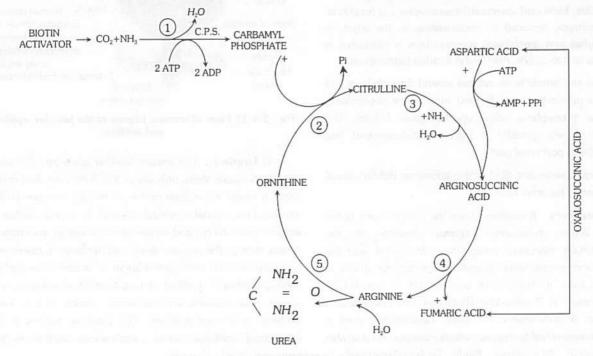

Fig: 5.4-12 Ornithine cycle

UNIVERSAL BOOK DEPOT 1960

Urine formation: Urine formation occurs in the kidneys. It involves three processes glomerular filtration, reabsorption and tubular secretion.

(1) Ultra filtration (Starling's hypothesis)

- (i) It is a passive process which takes place from the glomerulus into the Bowman's capsule. The glomerular epithelium has various micropores (diameter = 50 100 nm or $0.05 0.1 \mu\text{m}$) which increase the rate of filtration.
- (ii) The non colloidal part of the plasma as urea, water, glucose, salts, vitamin, minerals, nitrogenous waste are forced out from the glomerular capillaries into the Bowman's capsule by the high pressure of the blood in the glomerular capillaries. The pressure and resistence is high because the glomerular capillaries are narrower than the afferent renal arteries. Glomerular capillaries are about 50 times more permeable than capillaries elsewhere. Pressure is highest in glomerular capillaries than in capillaries else where, produce more filtrate.
- (iii) The effective filtration pressure that causes ultrafiltration is determined by three pressures.

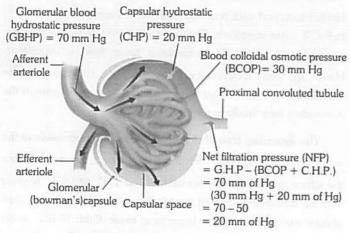

Fig: 5.4-13 Ultra filtration

(a) Glomerular blood hydrostatic pressure (G.B.H.P.): Hydrostatic pressure is force that a fluid under pressure exerts against the walls of its container.

G.B.H.P. = +70 mm Hg.

(b) **Blood colloidal osmotic pressure (B.C.O.P)**: The B.C.O.P. is the osmotic pressure created in the blood of glomerular capillaries due to plasma proteins albumin, globulin, and fibrinogen. It resists the filtration of fluid from the capillaries.

B.C.O.P. = 30 mm Hg.

B.C.O.P. in other body capillaries is 25 mm Hg

(c) Capsular hydrostatic pressure (C.H.P): C.H.P. is the pressure caused by fluid (filtrate) that reaches into Bowman's capsule and resists filtration.

C.H.P. = 20 mm Ha.

Effective filtration pressure (E.F.P.)/Net filtration pressure (N.F.P.): E.F.P. is glomerular blood hydrostatic pressure minus the colloidal osmotic pressure of blood and capsular hydrostatic pressure.

E.F.P. = G.B.H.P.
$$-$$
 (B.C.O.P. + C.H.P.)
= $70 \text{ mm Hg} - (30 \text{ mmg Hg} + 20 \text{ mm Hg})$
= $70 - 50$

E.F.P. = 20 mm Hg

☐ Net opposing filtration pressure

$$(N.O.F.P.) = B.C.O.P.+C.H.P.$$

= 50 mm Hg.

Glomerular filtrate: The plasma fluid that filters out from glomerular capillaries into Bowman's capsule of nephrons is called glomerular filtrate. It is a non colloidal part and possess urea, water, glucose, amino acid, vitamins, fatty acid, uric acid, creatine, creatinine, toxins, salts etc.

R.B.Cs, W.B.Cs, platelets and plasma proteins are the colloidal part of the blood and do not filtered out from glomerulus. Glomerular filtrate is isotonic to blood plasma.

Glomerular filtrate or Nephric filtrate

= Blood - (Blood cells + Plasma protein)

or

= Blood - (R.B.Cs + W.B.Cs + platelets + plasma protein)

or

= Plasma - Protein

Glomerular filtration rate (G.F.R.): G.F.R. is the amount of filtrate formed per minute in all nephrons of the paired kidney. There is a sexual difference. In male the rate is $120 - 125 \, ml/min$, in female it is $110 \, ml/min$. G.F.R. is affected by volume of circulating blood, neural activity, stretch response to pressure of the wall of the arteriole.

180 litre of filtrate is formed per day, out of it, only 1.5 litre of urine is produced per day which is 0.8% of the total filtrate.

Renal plasma flow: About 1250 *ml* (25% of cardiac output or total blood) blood circulates through kidneys each minute and of this blood, about 670 *ml* is the plasma. The latter is called the renal plasma flow (R.P.F.)

 $R.P.F. = 670 \, ml.$

Filtration fraction: This is the ratio of G.F.R. to R.P.F., and it is called filtration fraction.

Filtration fraction =
$$\frac{G.F.R.}{R.P.F.} = \frac{120}{670} = 0.17$$

(2) Selective reabsorption: Discovered by Richard and supporters.

UNIVERSAL BOOK DEPOT 1960

890 Excretory Products and their Elimination

Proximal convoluted tubule : P.C.T. is the pivotal site for reabsorption. Glucose, amino acid and Na^+ , K^+ ions are reabsorbed by active transport. Cl^- are reabsorbed by passive transport following the positively charged ions.

Active uptake of ions reduces the concentration of the filtrate and an equivalent amount of water passes into the peritubular capillaries by osmosis. (Here 80% water is reabsorbed by passive transport. It is also known as obligatory water reabsorption). Most of the important buffer bicarbonate (HCO_3^-) is also reabsorbed from the filtrate. P.C.T. absorb nearly 80–90% of filtered bicarbonate. Some urea is reabsorbed by diffusion . The rest remain in the filtrate to be removed in the urine.

Henle's loop: See counter current mechanism.

Distal convoluted tubule : When the level of plasma water falls, the posterior pituitary lobe release the antidiuretic hormone (ADH) which increases the permeablity of the distal convoluted tubule and the collecting duct to water. Water is reabsorbed from the filtrate by osmosis and a reduced amount of concentrated urine is produced (Here 13% water is reabsorbed by facultative reabsorption)

The distal convoluted tubule and the collecting duct actively reabsorbs sodium from the filtrate under influence of the adrenal hormone aldosterone which makes their walls permeable to ions. The reabsorption of Na⁺ brings about the uptake of an osmotically equivalent amount of water. But duct of Bellini is relatively impermeable to water. Bicarbonate ions are also reabsorbed in D.C.T.

- (3) Tubular secretion: It occurs as under -
- (i) Creatinine, hippuric acid and foreign substances (pigments, drugs including penicillin) are actively secreted into the filtrate in the PCT from the interstitial fluid. Hydrogen ions and ammonia (NH₃) are also secreted into the PCT.
- (ii) Potassium, hydrogen, NH_4^+ and HCO_3^- ions are secreted by active transport, into the filtrate in the DCT.
- (iii) Urea enters the filtrate by diffusion in the thin region of the ascending limb of Henle's loop.

Removal of H^+ and NH_4^+ from the blood in the PCT and DCT helps to maintain the pH of the blood between 6 to 8. Any variation from this range is dangerous.

Tubular secretion probably plays only a minor role in the function of human kidneys, but in animals, such as marine fish and desert amphibians which lack glomeruli and Bowman's capsules, tubular secretion is the only mode of excretion. When the blood pressure, and consequently the filtration pressure, drop below a certain level, filtration stops and urine is formed by tubular secretion only.

High threshold substances : Such substances are absorbed almost all. Example – Sugar, amino acids, vitamins, HCO_3^- and Na^+ etc.

Low threshold substances : They are absorbed in low concentration. Example – Urea, phosphate, uric acid, H^+ , K^+ .

Non threshold substances: They are not reabsorbed. Example – Creatinine and hippuric acid.

Diuretic substances: Normally, the amount of urine formed depends on the intake of water, dietary constituents, environmental temperature, mental and physiological states of the person. However, there are some substances which increase the volume of urine to be excreted, these substances are called diuretic substances. Exmaple – Tea, Coffee, alcohol etc.

Mechanism of urine concentration (Counter current mechanism of urine concentration): Mammals form hypertonic urine. The urine is made hypertonic with the help of counter current multiplier system. This process takes place in the Henle's loop and vasa recta and it involves mainly Na^+ and Cl^- . In P.C.T. urine is isotonic. The descending limb of loop of Henle is permeable to water. Its surrounding tissue fluid is hypertonic. Hence, the water moves out and the Na^+ and Cl^- moves in the descending limb by passive transport. Therefore, the filtrate in the descending limb finally becomes hypertonic.

The ascending limb of the Henle's loop is impermeable to the water. The Na^+ and Cl^- moves out by active transport. Hence the filtrate finally becomes hypotonic. The Na^+ and Cl^- re-enter into the descending limb of the Henle's loop. The collecting duct always passes through the hypertonic tissue fluid. Hence, water comes out osmotically making the filtrate hypertonic. Now in collecting duct glomerular filtrate is known as urine. Term urine first time used in collecting duct.

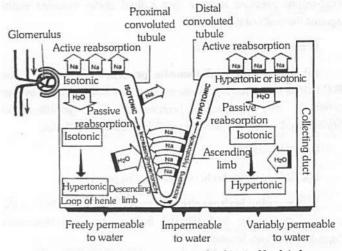

Fig: 5.4-14 Counter current multiplier in Henle's loop

UNIVERSAL BOOK DEPOT 1960

Table: 5.4-4 Summary of events occurring in a nephron

S.No.	Materials transferred in traces	Nephron region	Process involved	Mechanism
1.	Glucose, Amino acids, protein albumin, Vitamins, Hormones, Na ⁺ , K ⁺ , Mg ²⁺ , Ca ⁺² , H ₂ O, HCO ₃ ⁻ , Urea, Uric Acid, Creatinine, Ketone Bodies.	Bowman's capsule	Glomerular filtration	Ultrafiltration
2.	Glucose, Amino Acids, Hormones, Vitamins, Na ⁺ , K ⁺ , Mg ²⁺ , Ca ⁺²	Proximal convoluted tubule	Reabsorption	Active transport
3.	Cl-	Proximal convoluted tubule	Reabsorption	D
4.	H ₂ O	Proximal convoluted tubule	Reabsorption	Passive transport
5.	Urea	Proximal convoluted tubule		Osmosis
6.	H ₂ O	Narrow region of descending limb of	Reabsorption	Diffusion
		Henle's loop	Reabsorption	Osmosis
7.	Na+,K+,Mg+2,Ca+2,Cl-	Narrow region of ascending limb of Henle's loop	Reabsorption	Diffusion
8.	Inorganic ions as above	Wide part of ascending limb of Henle's loop	Reabsorption	Active transport
9.	H ₂ O	Distal convoluted tubule, collecting tubule, collecting duct	Reabsorption with ADH Help	Osmosis
10.	Na ⁺	Distal convoluted tubule, collecting tubule, collecting duct	Reabsorption with aldosterone help reabsorption secretion	Active transport
11.	Urea	Last part of collecting duct	Reabsorption with aldosterone help reabsorption secretion	Diffusion
12.	Creatinine, Hippuric Acid, Foreign substances	Proximal convoluted tubule	Reabsorption with aldosterone help reabsorption secretion	Active transport
13.	K+, H+	Distal convoluted tubule	Reabsorption with aldosterone help reabsorption secretion	Active transport
14.	NH ₃	Distal convoluted tubule	Reabsorption with aldosterone help reabsorption secretion	Diffusion
15.	Urea	Ascending limb of Henle's loop (Thin part)	Reabsorption with aldosterone help reabsorption secretion	Diffusion

Urine

The fluid and dissolved waste substances excreted by the kidneys constitute urine.

Quantity: An adult man normally passes about 1 to 1.8 litres of urine in 24 hours. The volume of urine depends upon (i) the fluid intake, (ii) level of physical activity, (iii) type of food taken and (iv) environmental temperature increase urine output. Less fluid intake and profuse sweating due to heavy physical work and high temperature reduce urine output. Certain substances such as tea, coffee and alcohol, increase urine output. These are said to be diuretic.

Physical properties: Urine is transparent yellowish fluid, but becomes turbid (cloudy) on standing, its colour depends on its concentration. Its colour is due to a pigment urochrome derived from the breakdown of haemoglobin from the worn-out RBCs. Colour of the urine is altered by certain materials taken such as beet, vitamin B complex and some drugs and diseases. It is hypertonic to blood plasma. Its specific gravity ranges between 1.001 to 1.035, being slightly higher than that of water. Its pH is 6. It depends on the diet. High protein food and fruits increase acidity whereas vegetables increase alkalinity. Urine has a characteristic unpleasant odour. If allowed to stand, urea is degraded by bacteria to ammonia which imparts a strong smell to urine.

Chemical composition: Urine consists of water and organic and inorganic substances. Water alone forms about 95% of it, other substances form only 5%. The organic substances are

mainly nitrogenous organic compounds include urea, uric acid, creatinine and hippuric acid. Of these, urea is the principal component of human urine. The non nitrogenous organic compounds include vitamin C, oxalic acid, phenolic substances include ammonia, and mineral salts such as chlorides, sulphates and phosphates of sodium, potassium, calcium and magnesium. Sodium chloride is the principal mineral salt of the urine. Urine also contains some other substances, such as pigments and drugs, and some epithelial cells, leucocytes, mucin, enzymes, and hormones.

Abnormal materials: Presence of proteins (albumins), bile salts, bile pigments, ketone bodies, blood, pus, microbes and more than a trace of glucose in the urine is pathological condition. Presence of glucose, protein, blood, ketone bodies and pus in the urine is called glucosuria, proteinuria, haematuria, ketonuria and pyuria respectively.

Renal threshold: A negligible amount of glucose is present in the urine. The highest concentration of a substance in the blood upto which it is fully reabsorbed from the glomerular filtrate is called its threshold. If its concentration in the blood exceeds its renal threshold, some of the filtered out substance is not reabsorbed and is excreted in the urine. For example, the renal threshold of glucose is 180 mg. per 100 ml. of blood. If its blood level exceeds 180 mg., some of the filtered out glucose is not reabsorbed and is passed in urine.

Conduction of urine and Micturition: Urine is produced and drained continuously by the nephrons into the renal pelvis. From here, it is carried down the ureters by peristaltic waves into trigonum vesicae and then into the body of the urinary bladder. The bladder serves to store the urine temporarily and also to pass it out at suitable intervals. The process of passing out urine from the urinary bladder is called urination or micturition, As urine collects, the muscular walls of the bladder distend to accommodate it. Distension of its walls stimulates the sensory nerve endings in the bladder wall and this sets up reflexes, which cause an urge to pass out urine. During the discharge of the urine, the bladder and urethral sphincters relax and the smooth muscles of the bladder wall gradually contract. This slowly drives the urine from the bladder through the urethra to the exterior. Reflux of the urine into the ureters is prevented because the terminal parts of the ureters pass obliquely through the bladder wall and are consequently closed when the bladder wall contracts around them. Relaxation and contraction of the urinary bladder are caused by impulses from the sympathetic and parasympathetic nerve fibres.

Micturition may be voluntarily postponed for some time until the pressure in the bladder rises too high to control. Micturition may also be voluntarily achieved even before sufficient urine has accumulated in the bladder. Normally an urge for micturition starts when the bladder is a little more than halffull of urine.

Table: 5.4-5 Urine constituants in man (in gram)

1.	Total volume	1,200 ml – per 24 h
2.	Water	1,140 ml
3.	Total solids	50 gm
4.	Glucose	0
5.	Protein	0
6.	Ketones	0
7.	Urea	30 gm
8.	Creatinine	1.6 gm
9.	Creatine	0.1 gm
10.	Hippuric acid	0.7 gm
11.	Urobilinogen	0.4 mg
12.	Porphyrins	50 – 300 μg
13.	Uric acid	0.7 gm
14.	NaC1	15.0 gm
15.	K	3.3 gm
16.	Ca	0.3 gm
17.	Mg	0.1 gm
18.	Fe	0.1 gm
		0.005 gm
19.	SO ₄	2.5 gm
20.	PO ₄	2.5 gm

Table: 5.4-6 Urine constituents in man (in %)

1.	Water	96%
2.	Urea	2%
3.	Uric acid	0.2%
4.	NH ₃	0.25%
5.	Creatinine	0.5%
6.	Hippuric acid	0.025%
7.	Salt	1%

Hormonal control of renal function

Hormonal controls of the kidney function by negative feedback circuits can be identified:

- (1) Control by antidiuretic hormone (ADH): ADH, produced in the hypothalamus of the brain and released into the blood stream from the pituitary gland, enhances fluid retention by making the kidneys reabsorb more water. The release of ADH is triggered when osmoreceptors in the hypothalamus detect an increase in the osmolarity of the blood above a set point of 300 mosm L⁻¹. In this situation, the osmoreceptor cells also promote thirst. Drinking reduces the osmolarity of the blood, which inhibits the secretion of ADH, thereby completing the feedback circuit.
- (2) Control by Juxtaglomerular apparatus (JGA): (Low Blood pressure triggers the Reninangiotensin pathway) JGA operates a multihormonal Renin-Angiotensin-Aldosterone System (RAAS). The JGA responds to a decrease in blood pressure or blood volume in the afferent arteriole of the glomerulus and releases an hormone, renin into the blood stream. In the blood, renin initiates chemical reactions that convert a plasma protein, called angiotensinogen, to a peptide, called angiotensin II, which works as a hormone. Angiotensin II increases blood pressure by causing arterioles to constrict. It also increases blood volume in two ways - firstly, by signaling the proximal convoluted tubules to reabsorb more NaCl and water, and secondly, by stimulating the adrenal gland to release aldosterone, a hormone that induces the distal convoluted tubule to reabsorb more Na+ and water. This leads to an increase in blood volume and pressure, completing the feedback circuit by supporting the release of renin.

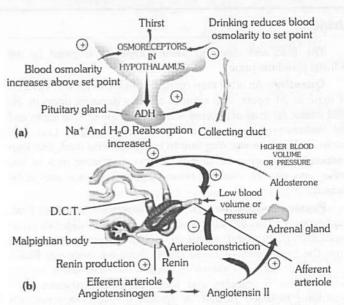

Fig: 5.4-15 Regulation of renal function by feedback circuits (a) Control by ADH (b) Control by RAAS

- (3) **Parathormone**: The hormone increases blood Ca⁺⁺ (Hypercalcaemia) and decreases PO₄ accordingly, it increases absorption of Ca⁺, increases excretion of PO₄.
- (4) Thyrocalcitonin: It increases excretion of Ca^{++} in the kidney.

- (5) Prostaglandin: The renal pyramids produce fatty acids of prostaglandins (P.G.) which participates in blood pressure regulation.
- (6) **Erythropoeitin**: It is secreted by juxtaglomerular apparatus and plays an important role in erythropoeisis (blood production).

Table: 5.4-7 Differences between Rennin and Renin

S.No.	Rennin	Renin
1.	It is secreted by peptic (zymogen) cells of gastric glands into the stomach.	It is secreted by specialisec cells in the afferent arterioles of the kidney cortex.
2.	Its secretion is stimulated by food.	Its secretion is stimulated by a reduction of Na ⁺ level in tissue fluid
3.	It is secreted as an inactive form prorennin which is activated to rennin by HCI.	It is secreted as renin.
4.	It is a proteolytic enzyme.	It is a hormone that acts as an enzyme
5,	It helps in the digestion of milk protein casein.	It converts the protein angiotensinogen into angiotensin.

Homeostatic regulatory functions of kidneys

By continuously eliminating metabolic wastes and other impurities, and even the surplus quantity of useful materials from blood plasma in the form of urine, kidneys play a vital role in homeostasis. Kidneys also operate certain other homeostatic regulatory mechanisms. Proper maintenance of the internal environment is known as homeostasis. All regulatory functions of kidneys can be enumerated as follows —

- (1) Osmoregulation: Being the universal solvent, water is the actual vehicle in ECF to transport materials between various parts of body. Water volume in ECF tends to vary considerably due to several reason, such as drinking, perspiration, diarrhoea, vomiting, etc. As described in previous pages, the kidneys maintain the water balance in ECF by diluting or concentrating urine.
- (2) Regulation of osmotic pressure: Osmolality of cytoplasm is mainly due to proteins and potassium and phosphate ions, whereas that of the ECF is mainly due to sodium, chloride and bicarbonate ions. Inspite of marked difference in chemical composition, the two fluids intracellular (cytoplasm) and extracellular (interstitium) must be isotonic, because if ECF becomes hypotonic, cells will absorb water, swell retaining apropriate number, mainly of sodium and chloride ions, kidneys maintain the normal osmolality of ECF.
- (3) **Regulation of pH**: Concentration of hydrogen ions $(NaH_2\ PO_4)$ in ECF is to be regulated at a constant value usually expressed as pH (minus log of H^+). The normal pH of ECF is about 7.4. A low pH, i.e. a high H^+ concentration causes acidosis, while a high pH, i.e. a low H^+ concentration causes alkalosis. Both of these conditions severely affect cellular metabolism. Several special control systems, therefore, operate in the body to prevent acidosis and alkalosis. These system are called acid-base buffer system. Kidneys play a key role in maintenance and operation of

these systems. Further, the kidneys regulate hydrogen ion concentration in ECF by excreting acidic or basic urine.

- (4) Regulation of electrolyte concentrations in ECF: The kidneys regulate, not only the total concentrations of water and electrolytes in ECF, but also the concentrations of individual electrolytes separately. This regulation is complex and is accomplished by tubular reabsorption and secretion under the control of hypothalamic and adrenal hormones.
- (5) **Regulation of RBC-count in blood**: In oxygen deficiency (hypoxia), kidneys secrete an enzyme into the blood. This enzyme reacts with plasma globulin to form erythropoietin. The latter substance stimulates bone marrow to produce more RBCs for enhancing O_2 -intake in lungs.
 - (6) Regulation of renal blood flow: See (R.A.A.S.).

Disorders of kidneys

- (1) **Pyelonephritis**: It is an inflammation of renal pelvis, calyces and interstitial tissue (*G.pyelos* = pelvis, tub; *nephros* = kidney; *itis* = inflammation). It is due to local bacterial infection. Bacteria reach here *via* urethra and ureter. Inflammation affects the countercurrent mechanism, and the victim fails to concentrate urine. Symptoms of the disease include pain in the back, and frequent and painful urination.
- (2) Glomerulonephritis: It is the inflammation of glomeruli. It is caused by injury to the kidney, bacterial toxins, drug reaction, etc. Proteins and R.B.Cs pass into the filtrate.
- (3) **Cystitis**: It is the inflammation of urinary bladder (*G.kystis* = bladder, -*itis* = inflammation). It is caused by bacterial infection. Patient has frequent, painful urination, often with burning sensation.
- (4) Uremia: Uremia is the presence of an excessive amount of urea in the blood. It results from the decreased excretion of urea in the kidney tubules due to bacterial infection (nephritis) or some mechanical obstruction. Urea poisons the cells at high concentration.
- (5) **Kidney stone** (**Renal calculus**): It is formed by precipitation of uric acid or oxalate. It blocks the kidney tubule. It causes severe pain (renal colic) in the back, spreading down to thighs. The stone may pass into the ureter or urinary bladder and may grow, and cause severe pain of blockage. When in bladder, the patient experiences frequent and painful urination and may pass blood in the urine. Surgery may be needed to remove stone and relieve pain.
- (6) Kidney (Renal) failure (RF): Partial or total inability of kidneys to carry on excretory and salt-water regulatory functions is called renal or kidney failure. Kidney failure leads to (i) uremia, i.e., an excess of urea and other nitrogenous wastes in the blood (G.ouron = urine, haima-blood); (ii) Salt-water imbalance; and (iii) stoppage of erythropoietin secretion.

Causes: Many factors can cause kidney failure. Among these are tubular injury, infection, bacterial toxins, glomerulonephritis (inflammation of glomeruli) arterial or venous obstruction, fluid and electrolyte depletion, intrarenal precipitation of calcium and urates, drug reaction, haemorrhage etc.

Artificial kidney

Artificial kidney called haemodialyser is a machine that is used to filter the blood of a person whose kidneys are damaged. The process is called haemodialysis. It may be defined as the separation of small molecules (crystalloids) from large molecules (colloids) in a solution by interposing a semipermeable membrane between the solution and water (dialyzing solution). It works on the principle of dialysis, i.e. diffusion of small solute molecules through a semipermeable membrane (G. dia = = through, lyo = separate). Haemodialyser is a cellophane tube suspended in a salt-water solution of the same composition as the normal blood plasma, except that no urea is present. Blood of the patient is pumped from one of the arteries into the cellophane tube after cooling it to 0°C and mixing with an anticoagulant (heparin). Pores of the cellophane tube allow urea, uric acid, creatinine, excess salts and excess H+ ions to diffuse from the blood into the surrounding solution. The blood, thus purified, is warmed to body temperature, checked to ensure that it is isotonic to the patient's blood, and mixed with an antiheparin to restore its normal clotting power. It is then pumped into a vein of the patient. Plasma proteins remain in the blood and the pores of cellophane are too small to permit the passage of their large molecules. The use of artificial kidney involves a good deal of discomfort and a risk of the formation of blood clots. It may cause fever, anaphylaxis, cardiovascular problems and haemorrhage. Kidney transplant is an alternative treatment.

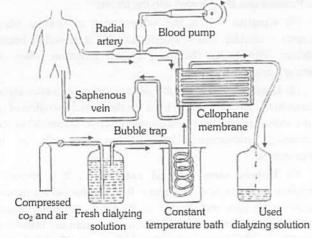

Fig: 5.4-16 Flow of blood through an artificial kidney for haemodialysis

Kidney (Renal) Transplantation

Meaning: Grafting a kidney from a compatible donor to restore kidney functions in a recipient suffering from kidney failure is called renal transplantation.

History: First kidney transplant was performed between identical twins in 1954 by Dr. Charles Hufnagel, a Washington surgeon, India's first kidney transplant was done on December 1, 1971 at Christian Medical College, Vellore, Tamilnadu. The recipient was a 35 years old person Shaninughan.

Eligibility: All patients with terminal renal failure are considered eligible for kidney transplantation, except those at risk from another life-threatening disease.

Donors: A living donor can be used in a kidney transplant. It may be in identical twin, a sibling, or a close relative. If the living donors are not available, a cadaveric donor may be used (cadaver is a dead body). Over half of the kidney transplants are from cadavers.

Success rate: A kidney transplant from an identical twin, called isogeneic graft or isograft, is always successful. A renal transplant from a sibling or a close relative or a cadaver, termed allogeneic graft or homograft, is usually successful with the use of an immunosuppressant that prevents graft rejection by body's immune response. Many renal transplant recipients are known to have retained functional grafts for over 20 years. Earlier, renal transplantation was limited to patients under 55 years. Now, however, with better techniques, kidney grafting has been done in selected patients in the 7th decade of life.

Pretransplant preparation: It includes haemodialysis to ensure a relatively normal metabolic state, and provision of functional, infection-free lower urinary tract.

Donor selection and kidney preservation: A kidney donor should be free of hypertension, diabetes, and malignancy. A living donor is also carefully evaluated for emotional stability, normal bilateral renal function, freedom from other systematic disease, and histocompatibility. Cadaveric kidney is obtained from previously healthy person who sustained brain death but maintained stable cardiovascular and renal function. Following brain death, kidneys are removed as early as possible, flushed with special cooling solutions, such as mannitol and stored in iced solution. Preserved kidneys usually function well if transplanted within 48 hours.

Recipient-Donor Matching : Recipient and donor are tested for 3 factors :

- (1) **Blood groups**: Recipient's blood group should be compatible with donor's blood group.
- (2) **Human leucocyte antigen (HLA):** It is a genetic marker located on the surface of leucocytes. A person inherits a set of 3 antigens from the mother and three from the father. A higher number of matching antigens increases the chances that the kidney graft will last for a long time.
- (3) **Antibodies**: Small samples of recipient's and donor's blood are mixed in a tube. If no reaction occurs, the patient will be able to accept the kidney.

Transplant procedure: Transplantation is done under general anaesthesia. Operation takes 3 or 4 hours. Cut is given in the lower abdomen. Donor's kidney is transplanted retroperitonealy in the iliac fossa. Artery and vein of new kidney are connected to the iliac artery and vein of the recipient. Ureter of the new kidney is connected to the urinary bladder of the recipient. Often the new kidney starts producing urine as soon as blood flows through it, but sometimes it may take a few weeks before it starts working. A week's stay in the hospital is necessary to recover from surgery, and longer if there are complications.

The new kidney takes over the work of two failed kidneys. Unless they are causing infection or high blood pressure, the old kidneys are left in place.

UNIVERSAL BOOK DEPOT 1950

Immunosuppression: Immunosuppression means to depress the immune response of the recipient to graft rejection. Prophylactic immunosuppressive therapy is started just before or at the time of renal transplantation. An ideal immunosuppressant suppress immunity against foreign tissue but maintains immunity against infection and cancer. The drug, named cyclosporin, is such an immunosuppressant. Use of antiserum to human lymphocytes is equally useful. It destroys T-cell mediated immune responses, but spares humoral antibody responses.

Accessory excretory organs

- (1) Skin: Many aquatic animals, such as Hydra and starfish, excrete ammonia into the surrounding water by diffusion through the body wall. In land animals, the skin is often not permeable to water. This is an adaptation to prevent loss of body's water. Mammalian skin retains a minor excretory role by way of its sudoriferous, or sweat glands and sebaceous, or oil glands.
- (i) Sweat gland: Sweat glands pass out sweat. The latter consists of water containing some inorganic salts (chiefly sodium chloride) and traces of urea and lactic acid. It also contains very small amounts of amino acids and glucose.
- (ii) Sebaceous glands: Oil glands pass out sebum that contains some lipids such as waxes, sterols, other hydrocarbons and fatty acids.
- (2) Lungs: Carbon dioxide and water are the waste products formed in respiration. Lungs remove the CO₂ and some water as vapour in the expired air. Lungs have access to abundant oxygen and oxidise foreign substances, thus causing detoxification and also regulate temperature.
- (3) **Liver**: Liver changes the decomposed haemoglobin of the worn-out red blood corpuscles into bile pigments, namely, bilirubin and biliverdin. These pigments pass into the alimentary canal with the bile for elimination in the faeces. The liver also excretes cholesterol, steroid hormones, certain vitamins and drugs via bile.
- (4) Large intestine: Epithelial cells of the colon transfer some inorganic ions, such as calcium, magnesium and iron, from the blood into the cavity of the colon for removal with the faeces.
- (5) Saliva: Heavy metals and drugs are excreted in the saliva.
- (6) Gills: Gills remove CO₂ in aquatic animals. They also excrete salt in many bony fish.

Osmoregulation

The regulation of solute movement and hence water movement which follows solutes by osmosis, is known as osmoregulation. Osmosis may be defined as a type of diffusion where the movement of water occurs selectively across a semipermeable membrane. It occurs whenever two solutions, separated by semipermeable membrane (the membrane that allows water molecules to pass but not the solutes) differ in total solute concentrations, or osmolarity. The total solute concentration is expressed as molarity or moles of solute per litre of solution. The unit of measurement for osmolarity is milliosmole per litre (mosm L⁻¹). If two solutions have the same osmolarity, they are said to be isotonic. When two solutions differ in osmolarity, the solution with

higher concentration of solute is called hypertonic, while the more dilute solution is called hypotonic. If a semipermeable membrane separates such solutions, the flow of water (osmosis) takes place from a hypotonic solution to a hypertonic one.

Osmoconformers are the animals that do not actively control the osmotic condition of their body fluids. They rather change the osmolarity of body fluids according to the osmolarity of the ambient medium. All marine invertebrates and some freshwater invertebrates are strictly osmoconformer. Osmoconformers show an excellent ability to tolerate a wide range of cellular osmotic environments.

Osmoregulators, on the other hand, are the animals that maintain internal osmolarity, different from the surrounding medium in which they inhabit. Many aquatic invertebrates are strict or limited osmoregulators. Most vertebrates are strict osmoregulators, i.e. they maintain the composition of the body fluids within a narrow osmotic range. The notable exception, however, are the hagfish (Myxine sp., a marine cyclostome fish) and elasmobranch fish (sharks and rays).

Osmoregulators must either eliminate excess water if they are in hypotonic medium or continuously take in water to compensate for water loss if they are in a hypertonic situation. Therefore, osmoregulators have to spent energy to move water in or out and maintain osmotic gradients by manipulating solute concentrations in their body fluids.

Tips & Tricks

- Anuria Failure of kidney to form urine.
- Cystitis Inflammation of urinary bladder.
- Filtration fraction Ratio between GFR (glomerular filtration rate) and RPF (renal plasma flow).
- S Gout Painful great toe (arthiritis) due to deposition of uric
- Maematuria Presence of blood cells in urine.
- Oedema Increased volume of interstitial fluid.
- Renal stone Stone formation in the nephrons of kidney due to accumulation of mainly calcium oxalates some phosphates and uric acid
- Polyuria Increased urine volume as in Diabetes insipidus and mellitus.
- Allantoin and allantoic acid are nitrogenous excretory products formed during embryonic development of amniotes with shelled eggs. Allantoin is also called embryonic waste by allantoic acid is stored in allantois foetal membrane.

- Certain animals are both ammonotelic and ureotelic e.g. Ascaris, earthworm, lung fish (African toad), etc.
- Chordate with flame cells is Branchiostoma (also called Amphioxus).
- Nocturia Increased volume of urine at night.

- condition).
- 1. Protein If protein is present in urine it may be due to infection or injury in kidney. (Mainly albumin is filtered)
- 2. Blood Due to infection and injury of kidney blood may appear in urine.
 - 3. Sugar In diabetes mellitus sugar appear in urine.
- 4. Bile or bile pigment In jaundice bile pigment appear in urine.
- 5. Ketone bodies In starvation and diabetes. Ketone bodies appear in urine.
- Diabetes mellitus Sugar appear in urine due to hyposecretion of insulin.
- hyposecretion of A.D.H.
- Diuretics Diuretic are drugs that increase the rate of urine flow. (Naturally occurring diuretic include caffine in coffee, tea, and cola soda, which inhibit Na+ reabsorption and alcohol in beer, wine and mixed drinks inhibits secretion of ADH).
- The most frequent protozoan seen in urine is Trichomonas vaginalis, a cause of vaginitis in females and urethritis in males.
- Both kidney and ureter are retroperitoneal organ.
- Urine gives a pungent smell if left for sometime. This smell is of ammonia formed by conversion of urea into ammonia by
- A starving person will excrete more urea because during starvation proteins are broken down for energy production.
- Cystolith Stone of the bladder.
- Euryhaline are organisms that can tolerate a wide range of salinity, stenohaline are organisms that can live within a narrow range of salinity.
- large amount of homogentistic acid in urine as a result of incomplete metabolism of amino acids. This causes blackening of urine on standing.

Excretory waste products

- Kidney crystals are solid clusters of 1.
- [CBSE PMT 1990]
- (a) Calcium nitrate and uric acid
- (b) Phosphate and uric acid
- (c) Calcium carbonate and uric acid
- (d) Calcium metabisulphite and uric acid
- Waste products of adenine and guanine (Purines) metabolism are excreted by man as

[CBSE PMT 1991; J & K CET 2002]

- (a) Ammonia
- (b) Urea
- (c) Uric acid
- (d) Allantois
- 3. Uricotelism is a method of conserving
- [CPMT 1992]

- (a) Na+ and K+
- (b) Space
- (c) Water
- (d) Energy

In man, the urea is mainly produced in

[CPMT 1992, 93, 2001; Manipal 1995; MP PMT 1998; RPMT 1999; BVP 2002; Kerala CET 2003; Odisha JEE 2005]

- (a) Liver
- (b) Kidneys
- (c) Gall bladder
- (d) Spleen
- A man takes large amount of protein. He is likely to excrete 5. [CPMT 2004] more amount of
 - (a) Water
- (b) Glucose
- (c) Urea and uric acid
- (d) Salts
- Which one of the following blood vessels in mammals would normally carry the largest amount of urea[MP PMT 1995, 97; BHU 2008; NEET (Phase-I) 2016]
 - (a) Hepatic portal vein
- (b) Hepatic vein
- (c) Renal artery
- (d) Hepatic artery
- Which one of the following is likely to accumulate in a dangerous proportion in the blood of a person whose kidney is not working properly

Or

The chief nitrogenous waste in urine of rabbit or terrestrial [CPMT 1992, 93] mammals is

- (a) Lysine
- (b) Ammonia
- (c) Sodium chloride
- (d) Urea
- The glomerular filtrate consists of
- [JIPMER 1993]
- (a) Urea, sodium chloride, fibrinogen and water
 - (b) Glucose, amino acids, urea, oxytocin and calcitonin
 - (c) Both (a) and (b)
 - (d) Urea, glucose, salts and water
- The body cells in cockroach discharge their nitrogenous 9. waste in the haemolymph mainly in the form of

[AIPMT 2015]

- (a) Potassium urate
- (b) Urea
- (c) Calcium carbonate
- (d) Ammonia
- The characteristic that is shared by urea, uric acid and ammonia is/are
 - (A) They are nitrogenous wastes
 - (B) They all need very large amount of water for excretion
 - (C) They are all equally toxic
 - (D) They are produced in the kidneys [NCERT; KCET 2009]
 - (a) A, C and D
- (b) A and D
- (c) A, C and B
- (d) A only
- Which one of the following characteristics is common both in humans and adult frogs

[NCERT; CBSE PMT (Mains) 2012]

- (a) Four-chambered heart
- (b) Internal fertilisation
- (c) Nucleated RBCs
- (d) Ureotelic mode of excretion
- Uric acid is the chief nitrogenous component of the 12. [CPMT 2009; CBSE PMT 2009] excretory products of
 - (a) Man
- (b) Earthworm
- (c) Cockroach
- (d) Frog
- Which of the following nitrogenous substance is highly toxic [NCERT; CPMT 1995; CBSE PMT 2001] Or

If liver from body is removed then which component of [HPMT 2005]

- (a) Urea
- (b) Uric acid
- (c) Amino acid

blood increases

(d) Ammonia

[BHU 2003]

- Almost all the aquatic animals excrete ammonia as the 14. nitrogenous waste product. Which of the following statement is not in agreement with this situation [KCET 2006]
 - (a) Ammonia is easily soluble in water
 - (b) Ammonia is released from the body in a gaseous state
 - (c) Ammonia is highly toxic and needs to be eliminated as and when formed
 - (d) Ammonia gets converted into a less toxic form called urea
- 15. The urine is

[NCERT; EAMCET 2009]

- (a) Hypotonic to blood and isotonic in medullary fluid
- (b) Hypertonic to blood and isotonic to medullary fluid
- (c) Isotonic to blood and hypotonic to medullary fluid
- (d) Isotonic to blood and hypertonic to medullary fluid
- 16. Aquatic reptiles are

[CBSE PMT 1999; BHU 2000; CPMT 2003]

- (a) Ammonotelic
- (b) Ureotelic over land
- (c) Ureotelic
- (d) Ureotelic in water
- Which of the following is the nitrogenous waste 17.

[CPMT 1999; JIPMER 2001]

- (a) Creatinine
- (b) Creatine
- (c) Guanine
- (d) All the above
- 18. Choose the wrong statement

[Kerala PMT 2012]

- (a) In ureotelic organisms, ammonia is not a product of metabolism
- (b) In mammals some amount of urea may be retained in the kidney matrix of ureotelics to maintain osmolarity
- (c) In fishes, kidneys do not play any significant role in the removal of ammonium ions
- (d) Urea and uric acid are less toxic than ammonia
- (e) Ammonia is readily soluble and can diffuse easily
- Which of the following are uricotelic animals AIIMS 2002; CBSE PMT 2004; CBSE PMT (Pre.) 2011]
 - (a) Rohu and frog
- (b) Lizard and crow
- (c) Camel and frog
- (d) Earthworm and eagle
- 20. Marine teleosts, undergoing putrefaction, emit sharp characteristic foul odour, which is due to the production of

[MP PMT 2002]

- (a) Trimethylamine
- (b) Hydrogen sulphide
- (c) Ammonia
- (d) Lactic acid
- 21. Which of the following is a metabolic waste of protein metabolism [NCERT; MP PMT 2002; BHU 2008]
 - (a) NH3, urea and CO2
 - (b) Urea, Oxygen and No
 - (c) Urea, ammonia and alanine
 - (d) Urea, ammonia and creatinine

- Excretion of nitrogenous waste products in semisolid form occur in [NCERT; Kerala CET 2003]
 - (a) Ureotelic animals
- (b) Ammonotelic animals
- (c) Uricotelic animals Which one is not correct
- (d) Amniotes
- (a) Humans Uriotelic
- (b) Birds Uricotelic
- (c) Lizards Uricotelic
- (d) Whale Ammonotelics
- 24. Man is

23.

- [Wardha 2005; CPMT 2010]
- (a) Ureotelic
- (b) Uricotelic
- (c) Ammonotelic
- (d) Both (b) and (c)
- 25. Which one of following statements is false [Kerala PMT 2007]
 - (a) Presence of albumin in urine is albuminuria
 - (b) Presence of glucose in urine is glycosuria
 - Presence of ketose sugar in urine is ketonuria
 - (d) Presence of excess urea in blood is uremia
 - (e) Presence of haemoglobin in urine is haemoglobinuria
- Animal which excrete urea produced during metabolism of 26. amino acids is [AFMC 2004]
 - (a) Ureotelism
- (b) Uricotelism
- (c) Ammonotelism
- (d) Aminotelism
- Which one of the following options gives the correct 27. categorisation of six animals according to the type of nitrogenous wastes (A,B,C), they give out

[NCERT; HP PMT 2005; CBSE PMT (Mains) 20121

	A-AMMONOTELIC	B-UREOTELIC	C-URICOTELIC
(a)	Pigeon, Humans	Aquatic Amphibia, Lizards	Cockroach, Frog
(b)	Frog, Lizards	Aquatic Amphibia, Humans	Cockroach, Pigeon
(c)	Aquatic Amphibia	Frog, Humans	Pigeon, Lizards, Cockroach
(d)	Aquatic Amphibia	Cockroach, Humans	Frog, Pigeon,

- The most abundant, harmful and universal waste product of 28. metabolism is [CPMT 2004]
 - (a) CO2
- (b) Uric acid
- (c) H₂O
- (d) None of these
- 29 The main nitrogenous waste of Hydra is
 - (a) Ammonia only
- (b) Urea only
 - (c) Uric acid only
- (d) Both (a) and (c)
- A person is undergoing prolonged fasting. His urine will be found to contain abnormal quantities of [CBSE PMT 2005]
 - (a) Fats
- (b) Aminoacids
- (c) Glucose
- (d) Ketones
- Urea is directly produced in mammals from [CPMT 2005] (a) Ammonia released by oxidative deamination

 - (b) Oxidative deamination of purines
 - (c) Breakdown of ornithine
 - (d) Breakdown of arginine
- Nitrogenous waste products are eliminated mainly as 32.

[KCET 2007]

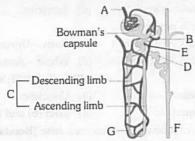

[CPMT 2004]

- (a) Urea in tadpole and uric acid in adult frog
- (b) Urea in adult frog and ammonia in tadpole
- (c) Urea in tadpole as well as in adult frog
- (d) Urea in tadpole and ammonia in adult frog

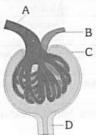

Excretory organs of different organism

See the following diagram and identify A, B, C, D, E, F and G [NCERT]

- (a) A Afferent arteriole, B Henle's loop, C Collecting duct, D - PCT, E - DCT, F - Peritubular capillaries, G-
- (b) A Afferent arteriole, B Peritubular capillaries, C -Henle's loop, D - DCT, E - PCT, F - Collecting duct, G-
- (c) A Efferent arteriole, B PCT, C Henle's loop, D -DCT, E - Peritubular capillaries, F - Collecting duct, G-Vasa recta
- (d) A Afferent arteriole, B Proximal convoluted tubule, C - Henle's loop, D - Distal convoluted tubule, E -Peritubular capillaries, F - Collecting duct, G- Vasa recta
- The given diagram represent the Malpighian body. Identify 2. INCERTI

- (a) A Afferent arteriole, B Efferent arteriole, C -Bowman's capsule, D - DCT
- (b) A Afferent arteriole, B Efferent arteriole, C -Bowman's capsule, D - Proximal convoluted tubule
- (c) A Afferent arteriole, B Efferent arteriole, C renal corpuscle, D - Proximal convoluted tubule
- (d) A Efferent arteriole, B Afferent arteriole, C -Bowman's capsule, D - Proximal convoluted tubule
- Which of the following does not have an excretory system 3.

[Kerala PMT 2011]

- (a) Myxine
- (b) Carcharodon
- (c) Balanoglossus
- (d) Asterias
- (e) Catla
- One of the following does the same work as is done by 4. [CBSE PMT 1996] nephridia in earthworm
 - (a) Flame cells in liverfluke (b) Myotomes in fish

 - (c) Statocysts in prawn (d) Parotid gland in toad

Which one of following correctly explains the function of a 5. specific part of a human nephron

[NCERT; CBSE PMT (Pre.) 2011]

- (a) Afferent arteriole: Carries the blood away from the glomerulus toward renal vein
- (b) Podocytes: Create minute spaces (slit pores) for the filtration of blood into the Bowman's capsule
- (c) Henle's loop: Most reabsorption of the major substance from the glomerular filtrate
- (d) Distal convoluted tubule: Reabsorption of K+ ions into the surrounding blood capillaries
- Which of the following is not an excretory organ of 6. [Odisha JEE 2010] vertebrates
 - (a) Lungs

(b) Skin

(c) Liver

- (d) Hepatopancreas
- The hormone secreted by kidney is [NCERT; MP PMT 2001] 7.
 - Gastrin

(b) Secretin

(c) Erythropoietin

- (d) Aldosterone
- Select the option which shows correct matching of animal 8. with excretory organs and excretory product

[NEET (Kamataka) 2013]

	Animal	Excretory organs	Excretory product
(a)	Labeo (Rohu)	Nephridial tubes	Ammonia
(b)	Salamander	Kidney	Urea
(c)	Peacock	Kidney	Urea
(d)	Housefly	Renal tubules	Uric acid

Forest of nephridia are present in

[RPMT 2005]

(a) Pharyngeal region

(b) Clitellar region

(c) Anal region

- (d) None of these
- Proboscis gland in Balanoglossus is associated with 10.

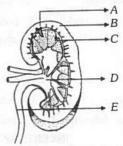

[Kerala PMT 2011]

(a) Digestion

(b) Respiration

(c) Circulation

- (d) Excretion
- (e) Reproduction
- Refer the following diagram and identify the parts of a [Kerala PMT 2006] kidney indicated

- (a) A=cortex, B=nephron, C=pelvis, D=medulla, E=ureter
- (b) A=cortex, B=medulla, C=nephron, D=pelvis, E=ureter
- (c) A=nephron, B=cortex, C=medulla, D=ureter, E=pelvis
- (d) A=nephron, B=cortex, C=medulla, D=pelvis, E=ureter
- (e) A=nephron, B=ureter, C=pelvis, D=medulla, E=cortex

20.	Which one is the excretory organ in the following	33.	- 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1
	[Kerala CET 2003; MP PMT 2013]	33.	Which is common to kidney and skeleton in mammals
	(a) Archaeocyte (b) Choanocyte (c) Pinacocyte (d) Solenocyte		[MP PMT 2009]
21.			(a) Cortex (b) Medulla (c) Pelvis (d) Radius
~1.	Haemodialysis helps in the patient having	34.	1-/
	(a) Uremia (b) Anaemia	J4.	If excess water passes out from the tissue without being
	(c) Diabetes (d) Goitre		restored by the kidneys, the cells would [CBSE PMT 1994] (a) Not be affected at all
22.	Which pollutant accumulates in liver and kidney [RPMT 2000]		(b) Shrivel and die
	(a) Copper (b) Mercury		
	(c) Lead (d) Cadmium		(c) Burst open and die
	(d) Cadillatti		(d) Take water from the plasma

- The size of filtration slits of glomerulus
- [WB JEE 2009]

- (a) 10 nm
- (b) 15 nm
- (c) 20 nm
- (d) 25 nm
- Which type of kidneys are found in amphibian (frog) 36.

[BCECE 2001; RPMT 2002]

- (a) Holonephric
- (b) Mesonephric
- (c) Pronephric
- (d) Metanephric
- Match the excretory organs listed under column I with the 37. animals given under column II. Choose the answer which gives the correct combination of alphabets of the two columns

	Column I	- 17	Column II
(Excretory organs)		(Animals)
A.	Nephridia	p.	Hydra
B.	Malpighian tubules	q.	Leech
C.	Protonephridia	r.	Shark
D.	Kidneys	s.	Round worms
	The same of the same	t.	Cockroach

[KCET 2004]

- (a) A = q; B = t; C = s; D = r
- (b) A = s; B = q; C = p; D = t
- (c) A = t; B = q; C = s; D = r
- (d) A = q; B = s; C = t; D = p
- The principal nitrogenous excretory compound in humans is 38. [CBSE PMT (Pre.) 2010] synthesised
 - (a) In the liver, but eliminated mostly through kidneys
 - (b) In kidneys but eliminated mostly through liver
 - (c) In kidneys as well as eliminated by kidneys
 - (d) In liver and also eliminated by the same through bile
- What is the characteristic of metanephric kidney 39.

[MP PMT 2000]

- (a) Hypotonic urine production
- (b) Excess secretion of uric acid
- (c) Loop of Henle
- (d) Hormone production
- Integumentary nephridia are also called **IDPMT 20041** 40.
 - (a) Enteronephric
 - (b) Exonephric
 - (c) Sometimes enteronephic and sometimes exonephric
 - (d) Both (a) and (b)
- In the urinogenital organs of rabbit which one of following part is present in male but not in female [CPMT 2005]
 - (a) Urethra
- (b) Fallopian tube
- (c) Vagina
- (d) Vas deferens
- Loop of Henle is meant for absorption of

[MP PMT 1996, 2002, 12; AFMC 1999; BHU 2000]

Or

What is removed from the filtrate at loop of Henle

[Odisha JEE 2009, 11]

- (a) Potassium
- (b) Glucose
- (c) Water
- (d) CO2

- [WB JEE 2012] Juxtaglomerular apparatus is made up of
 - (a) Juxtaglomerular cell, macula densa and lacis cell
 - (b) Juxtaglomerular cell, Purkinje cell and chief cell
 - (c) Juxtaglomerular cell, lacis cell and myoepithelial cell
 - (d) Juxtaglomerular cell, macula densa and argentaffin cell
- Which of the following passage way is part of cloaca of 44. [DPMT 2004] vertebrates
 - (a) Rectum
- (b) The reproductive tract
- (c) The urinary tract
- (d) All of these
- Renin is secreted by 45.
- IMP PMT 1996, 2001, 02;

Odisha JEE 2004; Kerala PMT 2005; MH CET 2015]

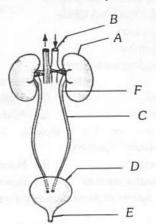

- Cortex
- (b) Medulla
- (c) Juxta glomerular cells
- (d) Podocytes
- Human kidney has 46.
- [MP PMT 1993]

- (a) Ciliated nephron
- (b) No loop of Henle
- (c) Mesonephric duct
- (d) Glomeruli concentrated in the cortex
- Which of the following is not a function of kidneys

[DPMT 1993]

- (a) Regulation of blood pressure
- (b) Removal of urea
- (c) Regulation of acidity of fluids
- (d) Secretion of antibiotics
- In the diagram of excretory system of human beings given 48. below, different parts have been indicated by alphabets; choose the answer in which these alphabets have been correctly matched with the parts which they represent

[KCET 2000; NEET 2013]

- (a) A = Kidney, B = Abdominal aorta, C = Ureters, D = Urinary bladder, E = Urethra, F = Renal pelvis
- (b) A = Kidney, B = Abdominal aorta, C = Urethra, D = Urinary bladder, E = Ureters, F = Renal pelvis
- (c) A = Kidney, B = Renal pelvis, C = Urethra, D = Urinary bladder, E = Ureters, F = Abdominal aorta
- (d) A = Kidney, B = Abdominal aorta, C = Urethra, D = Urinary bladder, E = Renal pelvis, F = Ureters
- In rabbit, the urinary bladder opens into [Odisha JEE 2012]
 - (a) Uterus
- (b) Urethra
- (c) Ureter
- (d) Vestibule

			BOOK DEPOT 1960
50.	In which one of the following organisms its excretory organs are correctly stated [NCERT; CBSE PMT (Mains) 2010]	5.	A terrestrial animal must be able to [CBSE PMT 2004]
	are correctly stated [NCERT; CBSE PMT (Mains) 2010] (a) Humans - Kidneys, sebaceous glands		(a) Actively pump salts out through the skin
	and tear glands		(b) Excrete large amounts of salts in urine
	(b) Earthworm - Pharyngeal, integumentary		(c) Excrete large amounts of water in urine
	and septal nephridia	6	(d) Conserve water
	(c) Cockroach - Malpighian tubules and	6.	Urinary excretion of Na is regulated by [AIIMS 1992]
	enteric caeca		(a) Anterior pituitary (b) Posterior pituitary
	(d) Frog - Kidneys, skin and buccal epithelium		(c) Adrenal cortex (d) Adrenal medulla
51.	Which one of the following body functions is not performed	7.	Mechanism of uric acid excretion in a nephron is
	by kidneys [RPMT 2002]		[AIIMS 1998]
	(a) Excretion		(a) Osmosis (b) Diffusion
	(b) Osmoregulation		(c) Secretion (d) Ultrafiltration
	(c) Regulation of blood volume	8.	The yellow colour of urine of the vertebrates is due to
	(d) Destruction of dead blood corpuscles		[CBSE PMT 1992; DPMT 1993; BHU 2004; MHCET 2011]
52.	The basic functional and structural unit of human kidney is		(a) Cholesterol (b) Urochrome
	[NCERT; DPMT 1993; MP PMT 1995, 2012;		(c) Uric acid (d) Melanin
	CBSE PMT 1997; BHU 1999; RPMT 1999, 2005; AFMC 2001; CPMT 2002; J & K CET 2005;	9.	Which segment of renal tubule is permeable to water but
	Bihar CECE 2006; Odisha JEE 2012]		nearly impermeable to salts [CBSE PMT 1992;
	Or Loop of Henle is found in		DPMT 2006; AIIMS 2011; GUJCET 2014]
	[CPMT 2001; MP PMT 2010; AMU (Med.) 2012]		(a) Proximal convoluted tubule
	(a) Nephron (b) Pyramid		(b) Descending limb of Henle's loop
	(c) Nephridia (d) Henle's loop		(c) Ascending limb of Henle's loop
3.	The kidneys of adult mammals are		(d) Distal convoluted tubule
	Bihar MDAT 1995; MP PMT 1999; BHU 2012]	10.	Sodium, water and phosphate reabsorption is maximum in
	(a) Opisthonephros (b) Pronephros		(a) Loop of Henle (b) Proximal tubule
	(c) Mesonephros (d) Metanephros		(c) Distal tubule (d) Collecting tubule
4.	In which of these animals, antennal gland or green glands	11.	tr
	functions as excretory organ [CPMT 2001; BHU 2003; Kerala PMT 2008]	11.	
	(a) Human being (b) Cockroach		(a) Excreted plasma proteins are acidic
	(c) Planaria (d) Prawn		(b) Potassium and sodium exchange generates acidity
	(e) Earthworm		(c) Hydrogen ions are actively secreted into the filtrate
	Physiology of excretion		(d) The sodium transporter exchanges one hydrogen ion,
	Nitrogenous waste in the Malpighian tubule flows into		for each sodium ion in peritubular capillaries.
	[Odisha JEE 2008]	12.	Which of the following glands does not help in excretion
	(a) Haemocoel (b) Vacuole		[Odisha JEE 2012]
	(c) Intestine (d) Duodenum		(a) Liver (b) Sweat glands
	The plasma resembles in its composition to the filtrate		(c) Pancreas (d) Both (a) and (c)
	produced by the glomerulus except the presence of	13.	At which stage of ornithine cycle arginase is used
	[DPMT 1992]		[AFMC 2006; DUMET 2010]
	(a) Glucose (b) Chloride		(a) Arginine- Ornithine (b) Ornithine- Citruline
	(c) Amino acids (d) Proteins		
	What for the ascending limb of Loop of Henle is permeable	14	2 ,, -3 -3 -3 -
	[MP PMT 1997; JIPMER 2002]	14.	Which of the following does not favour the formation of
	(a) Glucose (b) NH ₃		large quantities of dilute urine [AIPMT (Cancelled) 2015]
	(c) Na ⁺ (d) Water		(a) Caffeine (b) Renin
	Water reabsorption in the distal parts of kidney tubules is		(c) Atrial-natriuretic factor (d) Alcohol
200	regulated by [CPMT 2002; MP PMT 1992;	15.	Inflammation of joints due to accumulation of uric acid crystals is called as [NCERT; HP PMT 2005;
	DPMT 1992; Pb. PMT 1999; BVP 2000, 01; Odisha JEE 2005; RPMT 2005; AFMC 2010]		J & K CET 2008; AFMC 2012; MH CET 2015]
	(a) STH (b) TSH		(a) Gout (b) Myasthenia gravis
	(c) ADH (d) MSH		(c) Osteoporosis (d) Osteopalacia
	ACT ACCOUNT OF THE PROPERTY OF		(III Usipomalacia

(c) Osteoporosis

(d) Osteomalacia

Protein rich diet brings about relatively no change in one of the following constituents of urine (b) Creatinine (a) Urea (d) Ammonium salts (c) Uric acid When 2 to 3 drops of benedict's reagent are added to a urine sample and heated gently, it turns yellow. This colour change indicates that [KCET 2011] (a) Urine contains 2% glucose (b) Urine contains 0.5% glucose (c) Urine contains 1.5% glucose (d) Urine contains 1% glucose Which of the following cycles in liver is mainly responsible 18. [KCET 1994; BHU 2001; for the synthesis of urea Kerala CET 2003; MP PMT 2003; J & K CET 2010] (a) Citruline cycle (b) Kreb's cycle (d) Ornithine cycle (c) Nitrogen cycle Proximal convoluted tubule (PCT) is lined with 19. [Kerala PMT 2008] (a) Cuboidal epithelium (b) Simple brush border epithelium (c) Simple cuboidal brush border epithelium (d) Simple ciliated brush border epithelium (e) Columnar epithelium The part of a nephron which opens into the collecting duct is 20. [Kerala PMT 2012] /are (a) DCT (b) DCT and PCT (c) Henle's loop (d) Glomerulus (e) Bowman's capsule 21. Match the entries in column I with those in column II and choose the correct answer from the following Column II Column I Excess of protein level in urine Uremia Presence of high ketone B. Hematuria bodies in urine Presence of blood cells in urine C. Ketonuria Presence of glucose in urine D. Glycosuria Presence of urea in urine Proteinuria [NCERT; Kerala PMT 2006, 11; DPMT 2007; CPMT 2010] (a) A-5, B-3, C-2, D-4, E-1(b) A-4, B-5, C-3, D-2, E-1(c) A-5, B-3, C-4, D-2, E-1(d) A-3, B-5, C-2, D-1, E-4(e) A-2, B-1, C-3, D-4, E-5Which of the following disease shows the blockage of kidney tubules and causes severe back pain [GUJCET 2015] (a) Renal calculi (b) Kidney failure (c) Uremia (d) Nephritis In distal convoluted tubule of the nephrons (a) Na reabsorption requires energy

(b) Secretion of K ions does not require energy

(c) Water reabsorption requires energy

(d) Ammonia is secreted

The substance which is completely reabsorbed from the filtrate in the renal tubule under normal conditions is [CPMT 1993, 95] Or In nephrons there is complete absorption of [MP PMT 1999] (a) Urea (b) Salt (c) Glucose (d) Water Effective filtration pressure in glomerulus is caused due to 25. [NCERT; KCET 2011] (a) Powerful pumping action of the heart (b) Secretion of adrenaline (c) Afferent arteriole is slightly larger than efferent arteriole (d) Vacuum develops in proximal convoluted tubule and sucks the blood Which of the following function is performed by collecting [GUJCET 2015] tubule of kidney (a) In the maintenance of pH and ionic balance of blood by the secretion of H^+ and K^+ ions (b) Maintenance of pH of blood and removal of Na+ and K+ ions (c) Absorption of glucose and ammonia from the blood (d) None of above Which of the following causes an increase in sodium reabsorption in the distal convoluted tubule [CBSE PMT 2014] (a) Decrease in aldosterone levels (b) Decrease in antidiuretic hormone levels (c) Increase in aldosterone levels (d) Increase in antidiuretic hormone levels A large quantity of fluid is filtered every day by the nephrons 28. in the kidneys. Only about 1% of it is excreted as urine. The remaining 99% of the filtrate [KCET 2009] (a) Gets collected in the renal pelvis (b) Is lost as sweat (c) Is stored in the urinary bladder (d) Is reabsorbed into the blood Reabsorption of glucose from the glomerular filtrate in the kidney tubule is carried out by Reabsorption in the tubules of nephrons occurs by the [AIIMS 2001; AIEEE Pharmacy 2003] process of (b) Osmosis (a) Active transport (c) Brownian movement (d) Diffusion Maintenance of body potassium level is primarily by tubular 30. [AMU (Med.) 2010] (a) Absorption in PCT (b) Secretion in DCT and /or cortical collecting duct

(c) Absorption in DCT

(d) Secretion in PCT

Which one of the following pair of waste substances is removed from blood in ornithine cycle

[CBSE PMT 1996, 2005; AFMC 2000; BHU 2001] (b) Ammonia and urea (a) CO₂ and urea

(c) CO2 and ammonia

(d) Urea and sodium salt

IVERSAL OK DEPOT 1960

- The amino acid that acts as a carrier of ammonia from skeletal muscle to liver [DUMET 2010]
 - (a) Alanine
- (b) Methionine
- (c) Arginine
- (d) Glutamine
- Which one of the following is correct for a normal human [NCERT; WB JEE 2010; Kerala PMT 2012]
 - (a) pH of urine is around 8
 - (b) On an average, 25-30 mg of urea is excreted via urine
 - (c) Presence of ketone bodies in urine is an indicator of diabetes mellitus
 - (d) Glycosuria can be treated with hemodialysis
 - (e) Relaxation of smooth muscles of bladder and simultaneous contraction of urethral sphincter causes release of urine
- A fall in glomerular filtration rate (GFR) activates

[NCERT; CBSE PMT (Mains) 2012; KCET 2015]

- (a) Juxta glomerular cells to releases renin
- (b) Adrenal cortex to release aldosterone
- (c) Adrenal medulla to release adrenaline
- (d) Posterior pituitary to release vasopressin
- 35. The end product of ornithine cycle is

[AIIMS 1999; MH CET 2000]

- (a) Urea
- (b) Ammonia
- (c) Uric acid
- (d) Carbon dioxide
- 36. The glomerular filtrate contains

[NCERT:

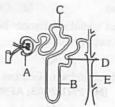

- JIPMER 1993; CPMT 2005; KCET 2009] (a) Blood minus cells and proteins
- (b) Blood minus cells
- (c) Blood minus proteins
- (d) Plasma minus cells and proteins
- The vessel leading blood (containing nitrogenous waste) into 37. the Bowman's capsule is known as [MP PMT 2002]
 - (a) Afferent arteriole
- (b) Efferent arteriole
- (c) Renal artery
- (d) Renal vein
- 38. Match the excretory functions of section I with the parts of the excretory system in section II. Choose the correct combinations from among the answers given

9.0	Section I	May 1	Section II
(i)	Ultrafiltration	(a)	Henle's loop
(ii)	Concentration of urine	(b)	Ureter
(iii)	Transport of urine	(c)	Urinary bladder
(iv)	Storage of urine	(d)	Malpighian corpuscles
	7.0	(e)	Proximal convoluted tubules

[Kerala CET 2005]

- (a) (i) (d), (ii) (a), (iii) (b), (iv) (c)
- (b) (i) (d), (ii) (c), (iii) (b), (iv) (a)
- (c) (i) (e), (ii) (d), (iii) (a), (iv) (c)
- (d) (i) (e), (ii) (d), (iii) (a), (iv) (b)
- (e) (i) (d), (ii) (a), (iii) (c), (iv) (b)
- Glomerular hydrostatic pressure is present in [CPMT 2005]
 - (a) Tubule of kidney
 - (b) Bowman's capsule
 - (c) Glomerulus of uriniferous tubule
 - (d) Malpighian tubule

The given diagram represents a single nephron from a mammalian kidney. Identify which of the numbered regions

- The site of ultrafiltration
- Particularly sensitive to ADH
- The main site for the reaborption of glucose and amino acid
- IV. Largely responsible for the adjustment of blood pH

[NCERT]

- (a) I A, II B, III D, IV E (b) I A, II B, III C, IV E
- (c) I A, II B, III C, IV D (d) I A, II E, III C, IV D
- Select the correct statement with respect to locomotion in 41 [NEET 2013]
 - (a) The joint between adjacent vertebrae is a fibrous joint
 - (b) A decreased level of progesterone causes osteoporosis in old people
 - (c) Accumulation of uric acid crystals in joints causes their inflammation
 - (d) The vertebral column has 10 thoracic vertebrae
- Find the incorrect statement regarding mechanism of urine formation in man [Kerala PMT 2009]
 - (a) The glomerular filtration rate is about 125 ml per
 - The ultrafiltration is opposed by the colloidal osmotic (b) pressure of plasma
 - (c) Tubular secretion takes place in the PCT
 - (d) Aldosterone induces greater reabsorption of sodium
 - (e) The counter current systems contribute in diluting the
- Separation of amino acid into amino and carboxyl group is known as [CPMT 2002; RPMT 2005]

Removal of amino group of amino acid to transform it into keto acid is [DPMT 2004]

- (a) Deamination
- (b) Excretion
- (c) Amination
- (d) Egestion
- The main function of Henle's loop is

[BVP 2001; Pb. PMT 2004; Wardha 2005]

- (a) Conservation of water
- (b) Filtration of blood
- (c) Passage of urine
- (d) Formation of urine
- Mark the wrong match from the following (a) Bowman's capsule
 - [CPMT 2010]
 - (b) DCT
- Glomerular filteration
- (c) Henle's loop
- Absorption of glucose Concentration of urine

(d) PCT

- Absorption of Na+and K+
- 46. Active transport is

[BHU 1999]

- (a) Formation of ATP
 - (b) Against the gradient using ATP
 - (c) Along gradient without using ATP
 - (d) Against the gradient without using ATP

47.	Ultrafiltration takes place in	56
	(a) Blood capillaries (b) Tissue fluid	
	(c) Glomerulus (d) Urinary bladder	
48.	Reabsorption of useful substances back into the blood the filtrate in a nephron occurs in [J & K CET 2	
	Or	
	In which part of kidney, Glucose and amino acids reabsorbed [MP PMT 2003; AFMC 2005; WB JEE 2	
	Or	.011
	The maximum amount of electrolytes and water (70-80	58
	Percent) from the glomerular filtrate is reabsorbed in wh	
	part of the nephron [NCERT; CBSE PMT (Pre.)2	
	WB JEE 2	
	(a) Proximal convoluted tubule	59
	(b) Loop of Henle	
	(c) Distal convoluted tubule	
	(d) Collecting duct	
49.	Filtration pressure in human kidneys is about	60
	(a) +15mm Hg (b) +70mm Hg	
	(c) +45mm Hg (d) +55 mm Hg	
50.	Volume of urine is regulated by

- (c) Glucose
- (d) Fatty acids
- 68. Which one is component of ornithine cycle

[MHCET 2003; BHU 2005; CPMT 2009]

- (a) Ornithine, citrulline and alanine
- (b) Ornithine, citrulline and arginine
- (c) Amino acid are not used
- (d) Ornithine, citrulline and fumaric acid
- 69. Select the correct statement [Kerala PMT 2011]
 - (a) The juxta medullary nephrons have reduced Henle's loop
 - (b) Vasa recta is well developed in cortical nephrons
 - (c) The PCT and DCT are situated in the medulla of the kidney
 - (d) The glomerulus encloses the Bowman's capsule
 - (e) The ascending limb of the Henle's loop extends as the DCT
- 70. Ornithine is converted into citruline by an enzyme
 - (a) Glutamic dehydrogenase
 - (b) Aspartic glutamic transaminase
 - (c) Carbamyl phosphate synthetase
 - (d) Ornithine carbamyl transferase
- Vasopressin stimulates reabsorption of water and reduction of urine secretion. Hence vasopressin is otherwise called

[NCERT; MP PMT 1996; Kerala CET 2005]

- (a) Sinovial fluid
- (b) Antidiuretic hormone
- (c) Neurotransmitter
- (d) Growth regulating substance
- (e) None of the above
- 72. The part of nephron involved in active reabsorption of sodium is [NEET (Phase-II) 2016]
 - (a) Descending limb of Henle's loop
 - (b) Distal convoluted tubule
 - (c) Proximal convoluted tubule
 - (d) Bowman's capsule

- Which of the following statements on human kidney is false
 [WB JEE 2016]
 - (a) Renal plasma flow is normally 660 ml/minute
 - (b) Blood flow in the cortex is greater than that in the medulla
 - (c) Reabsorption of ions and water occurs mainly in the distal convoluted tubules
 - (d) The renal blood flow is decreased in dehydration
- 74. Which of the following statements is correct [NEET 2017]
 - (a) The ascending limb of loop of Henle is impermeable to water
 - (b) The descending limb of loop of Henle is impermeable to water
 - (c) The ascending limb of loop of Henle is permeable to water
 - (d) The descending limb of loop of Henle is permeable to electrolytes

NCERT Exemplar Questions

- The following substances are the excretory products in animals. Choose the least toxic form among them [NCERT]
 - (a) Urea
- (b) Uric acid
- (c) Ammonia
- (d) Carbon dioxide
- 2. Filtration of the blood takes place at
 - place at [NCERT]
 (b) DCT
 - (b) Collecting ducts
- (d) Malpighian body
- 3. Which of the following statements is incorrect [NCERT]
 - (a) ADH prevents conversion of angiotensinogen in blood to angiotensin
 - (b) Aldosterone facilitates water reabsorption
 - (c) ANF enhances sodium reabsorption
 - (d) Renin causes vasodilation
- A large quantity of one of the following is removed from our body by lungs [NCERT]
 - (a) CO2 only
- (b) H₂O only
- (c) CO2 and H2O
- (d) Ammonia

and (A) iv

- 5. The pH of human urine is approximately
 - proximately [NCERT]
 - (a) 6.5 (c) 6

(d) (B) i,

(C) ii,

- (b) 7 (d) 7.5
- 6. Different types of excretory structure and animals are given below. Match them appropriately and mark the correct answer from among those given below [NCERT]

Excretory structure/organ Animals A. Protonephridia i. Prawn B. Nephridia ii. Cockroach C. Malpighian tubules iii. Earthworm D. Green gland or Antennal gland iv. Flatworms (a) (D) i, (C) ii, (B) iii and (A) iv (b) (B) i, (C) ii, (A) iii and (B) iv (c) (D) i. (C) ii, (A) iii and (B) iv

(B) iii

We can produce a concentrated/dilute urine. This is Which one of the following statements is incorrect [NCERT] facilitated by a special mechanism. Identify the mechanism. (a) Birds and land snails are uricotelic animals (b) Mammals and frogs are ureotelic animals (a) Reabsorption from PCT (c) Aquatic amphibians and aquatic insects (b) Reabsorption from collecting duct ammonotelic animals (c) Reabsoption/Secretion in DCT (d) Birds and reptiles are ureotelic (d) Counter current mechanism in Henle's loop/Vasa recta [NCERT] 8. Which of the following pairs is wrong Dialysing unit (artificial kidney) contains a fluid which is (a) Uricotelic ----- Birds almost same as plasma except that it has (b) Ureotelic ---- Insects (b) High urea (a) High glucose (c) Ammonotelic ---- Tadpole (c) No urea (d) High uric acid (d) Ureotelic ----- Elephant Which one of the following statements is incorrect [NCERT] Critical Thinking (a) The medullary zone of kidney is divided into a few conical masses called medullary pyramids projecting into the calyces Objective Ouestions (b) Inside the kidney the cortical region extends in between A kidney stone is[NCERT; Kerala CET 2003; Manipal 2005] the medullary pyramids as renal pelvis (a) Blockage by fats (c) Glomerulus alongwith Bowman's capsule is called the (b) Deposition of sand in kidney renal corpuscle (c) A salt such as oxalate crystallised in pelvis (d) Renal corpuscle, proximal convoluted tubule (PCT) and (d) Blockage by proteins distal convoluted tubule (DCT) of the nephron are What will happen if the stretch receptors of the urinary situated in the cortical region of kidney bladder wall are totally removed [CBSE PMT 2009] 10. Match the terms given in Column I with their physiological (a) Urine will not collect in the bladder processes given in Column II and choose the correct answer (b) Micturition will continue Column II Column I (c) Urine will continue to collect normally in the bladder Proximal convoluted tubule i. Formation of (d) There will be no micturition concentrated urine Stool of a person contains whitish grey colour due to ii. Filtration of blood B. Distal convoluted tubule [CBSE PMT 2002] malfunction of Henle's loop iii. Reabsorption of 70-(b) Spleen (a) Liver 80% of electrolytes (c) Kidney (d) Pancreas D. Counter-current mechanismi v. Ionic balance All of the following animals are ureotelic except E. Renal corpuscle v. Maintenance of [MHCET 2015] concentration (a) Frog (b) Snake gradient in medulla (d) Toad (c) Turtle [NCERT] Options Which of these is not a ketone body (a) A-iii, B-v, C-iv. [NCERT]

UNIVERSAL BOOK DEPOT 1960

- Consider the following statements
 - A. Flame cells are excretory structures in flatworms
 - B. Green glands are excretory organs in annelids
 - Columns of Bertini are the conical projections of renal pelvis into renal medulla between the renal pyramids

[Kerala PMT 2007]

- (a) A and B correct
- (b) B and C incorrect
- (c) A and C correct
- (d) A, B and C correct
- (e) A, B and C incorrect
- In which of the following organisms Malpighian tubule is found [Odisha JEE 2008]
 - (a) Honey bee
- (b) Frog
- (c) Ascaris
- (d) Rabbit
- Due to insufficient filtration in the Bowman's capsule, all are likely to happen except [AIIMS 1992]
 - (a) Accumulation of fluid in the body
 - (b) Increase in blood pressure
 - (c) Increase in blood urea level
 - (d) Loss of glucose through urine
- 13. Diuresis is a specific pathological condition which leads to

[MP PMT 2001]

- (a) Increased volume of urine excretion
- (b) Decreased volume of urine excretion
- (c) Increased glucose excretion
- (d) Decreased electrolyte concentration
- Podocytes are the cells, present in

[CPMT 2000; Odisha JEE 2004, 11; Kerala CET 2005]

- (a) Cortex of nephron
- (b) Inner wall of Bowman's capsule
- (c) Outer wall of Bowman's capsule
- (d) Wall of glomerular capillaries
- 15. In peritoneal dialysis, [KCET 2010]
 - (a) The blood is removed from the body and a natural filter is employed
 - (b) The blood is not removed from the body and a natural filter is used
 - (c) The blood is not removed from the body and an artificial filter is used
 - (d) The blood is removed from the body and an artificial filter is employed
- 16. Which is not a basic renal function

[Odisha JEE 2008]

- (a) Reabsorption
- (b) Secretion
- (c) Perfusion
- (d) Filtration
- If Henle's loop were absent from mammalian nephron, which of the following is to be expected

[NCERT; CBSE PMT 2003]

Or

Removal of proximal convoluted tubule from the nephron will result in [AIPMT (Cancelled) 2015]

- (a) The urine will be more dilute
- (b) There will be no urine formation
- (c) There will be hardly any change in the quality and quantity of urine formed
- (d) The urine will be more concentrated
- Which of the following is both osmoregulator as well as nitrogenous product [DPMT 2007]
 - (a) NH₃
- (b) Urea
- (c) Uric acid
- (d) All of these

19. Which one of the following statements is correct with respect to salt water balance inside the body of living organisms

[AIIMS 2005]

- (a) When water is not available camels do not produce urine but store urea in tissues
- (b) Salmon fish excretes lot of stored salt through gill membrane when in fresh water
- (c) Paramecium discharges concentrated salt solution by contractile vacuoles
- (d) The body fluids of fresh water animals are generally hypotonic to surrounding water
- 20. Fresh water bony fishes maintain water balance by

[MHCET 2000; BHU 2002, 04, 12]

- (a) Excreting a hypotonic urine
- (b) Excreting salt across their gills
- (c) Drinking small amount of water
- (d) Excreting wastes in the form of uric acid

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below :

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- Assertion : Ammonia should be eliminated from the body as rapidly as it is formed.
 - Reason : Ammonia is insoluble in water.
- Assertion : Urinary bladder and ureters are lined by transitional epithelium.
 - Reason : Ureters carry the urine to urinary bladder where it is stored temporarily.
- Assertion : Diabetes insipidus is marked by excessive urination and too much thirst for water.
 - Reason : Anti-diuretic hormone (ADH) is secreted by

the posterior lobe of pituitary gland. [AIIMS 2004]

- Assertion : During the physiology of excretion, deamination does not take place in liver cells.
 - Reason : Deamination is a process to make use of excess of amino acids which cannot be incorporated into the protoplasm.

[AIIMS 2001]

- Assertion: Phenylketonuria is a recessive hereditary disease caused by the body's failure to oxidize an amino acid phenylalanine to tyrosine, because of a defective enzyme.
 - Reason : It results in the presence of phenylalanine acid in the urine. [AIIMS 2000]

12.

Assertion

Reason

908 Excretory Products and their Elimination

 Assertion : Aquatic mammals like whales and seals are said to be ureotelic animals.

Reason : It is because of the fact that their main

nitrogenous waste product is urea.

 Assertion : In the descending limb of loop of Henle, the urine is hypertonic, while in ascending limb

of loop of Henle, the urine is Hypotonic.

Reason : Descending limb is impermeable to Na+, while ascending limb is impermeable to

H₂O. [AIIMS 1997; KCET 2010]

Assertion : Camel can go without water for long periods.

Reason : Camel stores water in the pouches of their

rumen and fat in their hump.

9. Assertion : Renal threshold of glucose is said to be 180

mg per 100 ml.

Reason : Glucose starts appearing in the urine when

its blood level exceed 180 mg per 100 ml

of blood.

Assertion : Earthworms excrete both ammonia and urea.

Reason : Excretion in earthworm depends on the

environment.

11. Assertion : The antidiuretic hormone increases the water

permeability of distal convoluted tubule.

Reason : In absence of ADH, water re-absorption is considerably reduced. [AIIMS 1994]

In birds and reptiles, main excretory product

is the combined form of urine and faeces.

: Birds and reptiles have no separate

chamber for excretion of urine and faeces.

13. Assertion : The glomerular filtrate resembles the

protein free plasma in composition and

osmotic pressure.

Reason : The glomerular capillary wall and inner

membrane of Bowman's capsule are

impermeable to large molecules.

14. Assertion : Kidneys maintain the osmotic

concentration of the blood.

Reason : Kidneys eliminate either hypotonic or

hypertonic urine according to the need of

the body.

15. Assertion: During micturition, urine is prevented from

flowing back into the ureters.

Reason : Urethral sphincters relax during micturition.

16. Assertion : Secreting hypotonic urine is effective in

reducing urinary loss of water.

Reason : Hypotonic urine is more concentrated and

higher in osmotic pressure than the blood.

17. Assertion : Urea is a less toxic excretory substance

comparatively to uric acid

Reason : Birds and insects are uricotelic animals.

[AIIMS 2010]

18. Assertion : Process of maintaining a constant internal

environment is known as homeostasis.

Reason : Kidneys are excretory and homeostatic organs. [AIIMS 2010]

19. Assertion : The functional unit of excretory organs of

lobsters is nephron.

Reason : The filtration of blood occur in the

malpighian body (the glomerulus and

Bowman's capsule). [AIIMS 2010]

20. Assertion: Mammals, living in deserts contain more

concentrated urine.

Reason : They contain very long loop of Henle in

their nephrons.

[AIIMS 2010]

Answers and Solutions

Excretory waste products

 (c) Main sources of uric acid are purines. Purines like adenine and Guanine change into xanthine which changes into uric acid

Guanine

Adenine \rightarrow xanthine \rightarrow uric acid

Nitrogenous waste substances such as Ammonia, urea, or uric acid are produced during protein metabolism according to the species. Small amount of nitrogenous waste substance are also produced during the metabolism of nucleic acids. Ammonia is the most toxic followed by urea and uric acid the latter is the least toxic.

- 3. (c) Excretion of uric acid is of greater advantage to land animals which have limited access to water. So uricotelism is an adaptation to terrestrial mode of life. Uric acid is expelled in solid state
- 4. (a) Ornithine cycle is a cyclic process of urea formation which operates in the mitochondria of liver cells and has been studied by kreb's and Henseleit.
- (c) Because they are the ultimate products of protein catabolism.
- 6. (b) Since urea formation takes place in liver.
- 7. (d) Because kidney removes urea.
- (d) Adult frog and human exhibit ureotelism because there excretory waste product is urea.

- 13. (d) The ammonia is highly toxic because it has high pH, So, it must either be metabolised or expelled immediately out of body, so its concentration remains low in the blood.
- 16. (c) Ureotelic animals include mainly amphibians and mammals besides its annelids (earthworm) elasmo branch fishes (shark) and aquatic animals are ureotelic.
- (b) The animals which excrete mainly uric acid are uricotelic. Terrestrial reptiles (lizards and snakes), birds, most insects are uricotelic animals.
- 20. (a) Marine teleosts form trimethylamine from their ammonia by methylation process which produce foul smell on oxidation.

Ammonia Methylation Trimethylamine

Oxidation TMO.

- 23. (d) Whale is ureotelic.
- 27. (c) Those animals who excrete Ammonia are called as Ammonotelic. Eg. Aquatic Amphibia.

Those animals who excrete Urea are called as Ureotelic. Eg. Frog, Humans $\,$

Those animals who excrete Uric Acid are called as Uricotelic. Eg. Pigeon, Lizards, Cockroach.

- **28.** (a) CO_2 and H_2O are the end product of complete aerobic oxidation of food through kreb's cycle and electron transport chain (E.T.C.) CO_2 is most abundant, harmful and universal waste product of metabolism.
- 29. (a) The main nitrogenous waste of Hydra is ammonia. Hydra has no organ of excretion, therefore, excretion of waste nitrogenous matter occurs directly by diffusion through all membrane.
- 32. (b) The main excretory product of frog is urea but excretory product of tadpole larva is ammonia. The urea along with some unnecessary salts and water is collected into the urinary bladder in the form of urine. It will be stored there for some time and is sent out through cloaca. So frog is described as ureotelic animal.

Excretory organs of different organism

- (a) Flame cells remove water and nitrogenous wastes in platyhelminthes.
- 5. (b) Podocytes are specialised squamous epithelial cells in the inner wall of Bowman's capsule. They give rise to foot like processes which form filtration slits for the filtration of blood into the Bowman's capsule.
- (c) Erythropoietin is secreted from glomerular cells and is concerned with the regulation of normal erythropoiesis.
- (b) The number of metanephridia varies from 2000-2500 in clitellar segments (but only 200-250 in each of the many other segments).
- (c) In the tadpoles of frogs, the ciliated funnels, nephrostomes, internally open into the uriniferous tubules.
- 14. (a) Animals like birds and lizards, which live in dry conditions, have to conserve water for their survival. So, they excrete nitrogenous waste in the form of uric acid.
- (c) Contractile vacuole found in Amoeba acts osmoregulatory processes.

- 19. (c) Ascaris has a 'H'-shaped tubular excretory system. It is supposed to be formed by a huge single excretory renette cell.
- **20.** (d) Solenocytes (flame cells) help in excretion in flatworms (platyhelminthes).
- 21. (a) Uremia is a condition of high concentration of urea, uric acid in blood etc. Through haemodialysis, waste molecules diffuse into dialysis fluid and the blood is then returned to the patient body.
- **25.** (b) The renal columns of Bertini is the part of cortex continued inside medulla between pyramids.
- 26. (d) Nephrons are morphological and physiological units of kidney. Man has 10-12 lac (106) nephrons in each kidney.
- 28. (c) Malpighian corpuscle (renal corpuscle) consists of Bowman's capsule and glomerulus.
- 29. (a) The epithelial cells of PCT have brush border due to the presence of abundant microvilli.
- 40. (b) Integumentary nephridia are also called exonephric nephrida. These are smallest V-shaped and without nephrostome. Integumentary nephridia are scattered in body wall of Pheretima.
- (d) Vas deferens or sperm duct is associated with male reproductive system which arises from cauda epididymis.
- 45. (c) Renin is an enzyme released by the juxtamedullary cells into plasma where it converts angiotensinogen into angiotensin I.
- 50. (b) Earthworm has 3 types of nephridia.
- 51. (d) Kidney is an excretory organ performing osmoregulation and regulation of blood volume and along with excretion of nitrogenous wastes but never associated with phagocytosis.
- 52. (a) Nephron is the structural and functional units of kidney, which extract wastes from the blood. It is also called renal tubules or tubule. Each nephron is about 6 cm long and is formed of two parts i.e., Bowman's capsule and body of renal tubule.
- 53. (d) In amniotes (reptiles, birds and mammals) kidneys are mesonephros in embryonic life but are metanephros in adult stage.
- 54. (d) In crustaceans, antennary gland or green gland is the chief excretory organ which eliminate ammonia from the animal body.

Physiology of excretion

- (d) Due to large size, protein can't be filtered through the filtration slits. So they are absent in glomerular filtrate.
- (c) Water is reabsorbed in distal convoluted tubules under the influence of antidiuretic hormone (ADH) secreted by posterior lobe of pituitary gland.
- 5. (d) Uric acid is least soluble nitrogenous waste and one gm of uric acid needs only 10 ml of water to be expelled out of body. So excretion of uric acid is of greater advantage to land animals which have limited access to water. So uricotelism is an adaptation to terrestrial mode of life.
- (c) Through mineralocorticoids which is secreted by adrenal cortex.
- 8. (b) Urine is a transparent, light yellow liquid with a slightly acidic pH (average pH 6.0) the colour of urine is caused by the pigment urochrome, which is a breakdown product of haemoglobin from worn out red blood corpuscles.

- (b) In descending limb of loop of Henle, water is reabsorbed due to increasing osmolality of interstitial fluid. Sodium and other solutes are not reabsorbed here. The filtrate become hypertonic to blood plasma. In ascending limb of loop of Henle, solutes (Na, K, Ca, Mg, Cl) are reabsorbed whereas it is impermeable to water.
 - In distal convoluted tubule, there is active reabsorption of sodium ions from the filtrate under the influence of aldosterone.
 - Collecting duct reabsorb the water and also Na^+ under the influence of aldosterone.
- 10. (b) About 65 percent of the glomerular filtrate is normally reabsorbed in the proximal convoluted tubule before reaching the loop of Henle. Glucose, amino acids, vitamins, hormone, sodium, potassium, chlorides, phosphates, bicarbonates, much of water and some urea from the filtrate are absorbed.
- **14.** (b) Renin does not favour the formation of large quantities of dilute urine.
- 18. (d) The actual process of urea synthesis is a repetitive cyclic sequence of a few reactions occurring continuously in the liver cells. Formation and transformation of three amino acids, namely ornithine, citrulline, and arginine. This cycle is variously referred to as ornithine, arginine or urea cycle.
- 23. (a) Reabsorption of Na⁺ in the tubules is an active process.
- **24.** (c) Complete reabsorption by active transport takes places for glucose in the PCT.
- (c) Aldosterone stimulates Na⁺ and water reabsorption in DCT.
- 29. (a) Reabsorption of glucose from the glomerlular filtrate in the kidney tubule is carried out by active transport.
- (c) Ornithine cycle removes two waste products from the blood in liver. These are NH₃ and CO₂.
- 35. (a) Ornithine cycle is meant for urea synthesis and ureotelic animals synthesize urea from ammonia in their liver cells.
- **36.** (a) Glomerular filtrate = Blood (Blood corpuscles + plasma proteins)

= Blood plasma - proteins

- 43. (a) Deamination is the removal of surplus amino acids or removal of amino group from carboxyl group with the formation of ammonia and keto acid.
- 44. (a) Loop of henle is a 'U' shaped segment of nephron located in the renal medulla. It helps in conservation of water during counter current mechanism.
- 46. (b) Active transport is movement across the cell membrane against the gradient with the use of ATP.
- (c) Ultrafiltration takes place through semipermeable walls of glomerulus and Bowman's capsule.
- 48. (a) 100% reabsorption of useful substances e.g. glucose takes place at proximal convoluted tubules.
- 49. (a) Effective filtration pressure in man is + 15 mm Hg. In case of horse and some other mammals it is + 25 mm Hg.
- **50.** (c) Water is reabsorbed in DCT under the influence of ADH secreted by posterior lobe of pituitary gland. This make the filtrate isotonic to blood plasma and aldosterone is associated with the excretion of K⁺ and H⁺ ions some Cl⁻ ions are also reabsorbed.
- 56. (a) Process of passing out of urine is called micturition. During discharge of urine urethral sphincters relaxes and smooth muscles of bladder wall contract gradually.

58. About 19% water is reabsorbed by the action of the posterior pituitary Anti diuretic hormone (ADH) or vasopressin.

59. In Bowman's capsule PCT and DCT are in renal cortex, whereas, loops of Henle are in medullary pyramids.

(d) The filtrate is isotonic to blood plasma (in proximal 60. convoluted tubule) and the filtrate becomes hypertonic to blood plasma (in descending limb of loop of Henle) The filtrate is hypotonic to blood plasma (in ascending limb at loop of Henle) in distal convoluted tubule ADH make the filtrate isotonic to blood plasma.

(b) In a healthy adult individual, the golmerular filteration 61. rate is 125 ml/min that is 180 liter/day, but about 99% of the filterate is reabsorbed producing around 1 to 1.5

liter urine/day.

63. (c) If urine is allowed to stand for some time it smells strongly of ammonia due to bacterial degradation of urea to ammonia.

When someone drinks lot of water which is not required by his body, the osmolarity of the blood will decrease. The decrease in osmolarity will inhibit the release of ADH. ADH not released DCT becomes less permeable to water, and excess of water is eliminated.

(a) Thromboxanes are synthesized in platelets and upon 66. release cause vasoconstriction and platelet aggregation. Prostaglandins release by blood vessels affect blood

68. Ornithine cycle is also called urea cycle which takes place in the mitochondria of liver cells. The amino acid arginine and citrulline are formed during formation of urea.

73. Reabsorption of ions and water occurs mainly in PCT

Critical Thinking Questions

1. Kidney stone is a crystallized chemicals like uric acid, calcium oxalate and calcium phosphate.

3. Since the liver gives colour to the faeces by changing the decomposed haemoglobin into bile pigments - bilirubin and biliverdin.

- 5. In human and most other mammals, acetyl Co-A formed in the liver during oxidation of fatty acids can enter the citric acid cycle or can be converted to the "ketone bodies" (e.g., Acetone, Acetoacetate and D - β hydroxy butyrate) for export to other tissue.
- Collecting duct receives the collecting tubules of several 7. nephrons. 8.

(a) Other kidney will enlarge in size to perform extra work of missing kidney (compensatory hypertrophy).

(d) Insufficient filtration will increase the blood urea level 12. because all the quantity of urea produced by liver would not be filtered through glomerular capsule. Loss of glucose through urine always takes place due to insufficient reabsorption.

14. (b) Podocytes or foot cells are specialised cells of peculiar shape present in the epithelium visceral inner layer of Bowman's capsule, surrounding the glomerulus. They possess foot like process or projections, the pedicers.

Hence, called as foot cells.

17. (a) The main function of loop of Henle is absorption of water . Hence, in its absence, water is not absorbed and dilute urine is passed out.

Outer wall of Bowman's capsule is made of squamous cells. 19. (a) Camels produce nearly dry faeces and highly concentrated urine. In the scarcity of water they use only metabolic water and store urea in their body tissue.

20. (a) Fresh water bony fishes take a large amount of water. To get rid of excess water, they pass out hypotonic urine (which is more dilute than blood plasma).

Assertion and Reason

Ammonia is the basic nitrogenous catabolite of proteins. It is highly soluble in water and highly toxic to the animal. So its concentration must be kept very low in the blood. For this reason ammonia should be eliminated as rapidly from the body as it is formed. A large volume of water is needed by the animals to dissolve ammonia and eliminate it from the body. So, its elimination in urine involves considerable loss of water from the body.

Urinary bladder and ureters of excretory system are lined by transitional epithelium because it is a stretchable epithelium, hence the urinary bladder and ureters may be considerably stretched without getting torn when they are filled with urine. Ureters are thin muscular tubes which emerge from the hilum of each kidney. Urine enters the ureters from the renal pelvis and is conducted along the ureters by peristaltic waves on their walls. Ureters from both the kidneys finally open into urinary bladder which is a hollow muscular sac. In this way urine from both the kidneys is drained into the urinary bladder which stores it temporarily.

Antidiuretic hormone (ADH) or vasopressin is secreted from posterior pituitary gland. It is released in response to a fall in the water content of blood plasma and lead to an increase in the permeability to water of the distal and collecting tubules of the nephron. Deficiency or hyposecretion of ADH results in diabetes insipidus. Diabetes insipidus is characterised by micturating dilute urine several times a day which results in excessive thirst (polydipsia) and dehydration.

(e) Deamination is to make use of excess of amino acid which cannot be incorporated into the protoplasm by removal or protein or aminoacids or amino group from carboxyl

group with the formation of ammonia and keto acid.

Phenylketonuria results when there is a deficiency of liver enzyme phenyl alanine hydroxylase that converts phenyl alanine into tyrosine. It results with a high level of phenyl alanine in blood, tissue fluids and urine.

Ureotelism is defined as the urinary elimination of nitrogen mainly as urea. Aquatic mammals like whales and seals are said to be ureotelic animals because their major nitrogenous waste product is urea. As a matter of fact, ammonia is the basic nitrogenous catabolite of protein but since ammonia is highly toxic to the animals, therefore, its concentration must be kept very low in the blood.

7.

Descending limb is permeable to water but not to Na+. Consequently water moves out into interstitium and concentration of Na+ in tubular filtrate rises making the filtrate hypertonic. Ascending loop is impermeable to water

but permeable to Na+ and makes the filtrate hypotonic. Camels have the ability to withstand water deprivation for long periods. But they do not store any water in the pouches of their rumen. The fat of hump is not particularly useful as a source of water because respiration must be enhanced to oxidise fat for producing water and this enhances respiratory loss of moisture. They reduce urinary water loss by secreting small volume of the urine much more hypertonic than the human urine. They lose far less water in the sweat, because they sweat only when their body temperature rises by as much as 60°C, compared to all other mammals. These factors are mainly responsible for the camel's ability to go without water for long periods.

- (a) Renal threshold of a substance is its highest concentration in the blood, upto which it is totally reabsorbed from the glomerular filtrate. Renal threshold of glucose is about 180 mg per 100 ml. It is totally reabsorbed and does not appear in the urine so long as its blood level does not exceed 180 mg. But when its blood level exceeds 180 mg, some of the filtered glucose is left unabsorbed in the tubules and consequently appears in the urine. Some substances which are either totally reabsorbed actively or most of their amounts are reabsorbed actively are called high threshold substances. High threshold substances are excreted in the urine only when their blood concentration is considerably high, for example glucose and amino acids.
- 10. (a) Earthworms excrete ammonia when sufficient water is available, because a large volume of water is needed by the animal to dissolve ammonia and eliminate it from, the body. Whereas in drier environment the animal eliminates urea as it requires only considerable amount of water for the excretion of urea because urea is very soluble in water.
- 11. (b) ADH is secreted by pituitary gland. It increases the water permeability of distal convoluted tubules and collecting tubules, hence, plays a significant role in water re-absorption. The absence of ADH will reduce water reabsorption which may lead to water diuresis or diabetes insipidus.
- 12. (a) In birds and reptiles, ureters and the rectum open into a common sac called the cloaca (as there is no chamber for urine and faeces) for these two which stores both, and reabsorbs water from them and ultimately excretes these white and brownish black material along with aqueous fluid.
- (a) Glomerular filtrate is the protein free fluid which is filtered 13. from the blood of glomerular capillaries to the lumen of the Bowman's capsule. This process is called glomerular filtration. About one-fifth of the total volume of plasma flowing through the kidneys is filtered out as the glomerular filtrate. The filtration occurs across the membrane made of the glomerular capillary wall and the inner membrane of the Bowman's capsule. The pores of this following membrane are impermeable to large molecules or particles. Large particles like blood cells and protein macromolecules do not normally enter into the glomerular filtrate. But smaller molecules like glucose, urea, creatinine, amino acids and mineral salts are filtered into the Bowman's capsule in concentrations more or less similar to their respective concentrations in the plasma. The filtrate therefore almost resembles the protein free plasma in composition and osmotic pressure.
- 14. (a) Kidneys play an essential role in maintaining the concentration and osmotic pressure (osmoconcentration) of blood. When water intake of an animal is very high, the urine excreted has to be hypotonic i.e., dilute and lower in osmotic pressure than their blood in order to remove the excess of water contrary to this, when there is a threat of excessive water loss from the body; the urine needs to be hypertonic more concentrated and higher in osmotic pressure than their blood, to reduce the loss of water with urine. In this way, the osmotic concentration of the blood is maintained.

- Besides functioning as a temporary reservoir of urine, the urinary bladder also evacuates the urine by the process of micturition at suitable intervals. When enough urine has accumulated in the bladder to distend the bladder and raise its pressure sufficiently, a spontaneous nervous activity (reflex) is initiated; this causes the smooth muscles on the bladder wall to contract and the urethral sphincters, which guard the urethra, to relax. Urine consequently flows from the bladder through the urethra to the exterior. But it is prevented from flowing back into the ureters, because the terminal part of each ureter passes obliquely through the bladder wall and is consequently closed due to compression by the contracting bladder muscles.
- When there is a threat of excessive water loss from the body of the animal, then the urine excreted needs to be hypertonic and not hypotonic because excessive water loss from the body posses the threat of a rise in osmoconcentration of the blood. Since hypertonic urine is more concentrated and higher osmotic pressure than the blood, therefore it helps in reducing the loss of water with urine. Mammals and birds can excrete hypertonic urine which is more concentrated than their blood. For this, an isotonic glomerular filtrate is first filtered into the Bowman's capsules of nephrons in kidneys. The tublues of nephrons then reabsorb a large volume of water from the glomerular filtrate not accompanied by the reabsorption of proportionate amounts of solutes. This leaves the urine more concentrated than the blood which is very effective in reducing the urinary loss of water.
- 17. (e) Urea is more toxic than uric acid and less toxic to ammonia Ammonia > Urea > Uric acid
 Urea formation takes place in kidneys.

Urea formation takes place in kidneys. Birds and insects are uricotelic animals.

- 18. (b) Walter Cannon (1932) was introduced the term homeostasis (homeios = same; stasis = standing). Homeostasis maintains the stability of the cell environment and this way provides the organism with a degree of independence of the environment; in order to achieve stability. Mammals have two kidneys which perform excretory function and maintain urea level in blood.
- 19. (d) Nephron is the principal functional unit of the kidney of vertebrates. Its number reaches to one million in each kidney.
 Filtration of blood occurs in Malpighian body, later is composed of a tuft of capillaries called the glomerulus together with the cupped end of the renal tubules,

known as Bowman's capsule.

20. (a) Functional unit of kidney is known as nephron. Later contains a tubular region between proximal and distal convoluted tubule, the loop of Henle. The length of loop of Henle is proportional to the concentration of urine. The mammals (chordates) living in desert contain longer loop of Henle in their nephrons. Due to this, these animals contain more concentrated urine.

ET Self Evaluation Test

 Column I contains some terms and Column II contains their meanings. Match them properly and choose the right answer

in the	Column I		Column II
A.	Glycogenesis	1.	Conversion of glycogen to glucose
B.	Glycosuria	2.	Conversion of glucose to glycogen
C.	Gluconeogenesis	3.	Excretion of glucose in urine
D.	Glycogenolysis	4.	Conversion of noncarbohydrate sources to glucose
	Marin James II.	5.	Conversion of glucose to starch

- (c) Less fats in his urine
- (d) More glucose in his blood

Answers and Solutions

1	b	2	C	3	b	4	b	5	d
6	d	7	c	8	a	9	d	10	-

- (c) The condition in which kidney failed to form urine is called anuria.
- (b) The composite structure of Bowman's capsule and glomerulus in knows as malpighian body or malpighian corpuscles after the italian microscopist Marcello Malpighi.
- 6. (d) The process of urea formation operates in mitochondria of Liver cells. Transamination means transference of an amino group (-NH₂) from an amino acid to another substance. This process is essential for growth and in case of vertebrates it takes place in liver.
- 8. (a) Filtration takes place through semipermeable walls of glomerulus and Bowman's capsule. Glomerulus and Bowman's capsule are collectively called malpighian corpuscle.
- (d) Renin change plasma protein, called angiotensinogen to a peptide called angiotensin.
- 10. (b) As urea is the main excretory product of mammals and if the person is starving, he will have less urea in his urine.

The study of bone structure and treatment of bone disorders is called osteology. The specialized branch of medicine that deals with preservation and restoration of skeletal system, joints is called orthopedics. Bones are made up of a protein called ossein and cartilage are made of a protein called chondrin. Hence study of bones is called osteology and study of cartilage is called chondrology. Body of animals (vertebrates) is supported by skeleton.

Skeleton

The hardened tissues of the body together form the skeleton (sclero = hard). Skeleton of invertebrates is most often secreted on the surface, forming a lifeless or dead exoskeleton. Whereas skeleton of vertebrates develops most often underneath the surface forming a living or growing endoskeleton. Three types of skeletons develop in vertebrates:

- (1) Epidermal/Horny exoskeleton: These include hard and horny keratinized derivatives of epidermal layer of skin, such as claws, most reptilian's scales, bird feathers and mammalian hairs, horns, nails and hoofs, etc. All living amphibians lack an exoskeleton.
- (2) Dermal/Bony skeleton: Dermal bony skeleton is derived from the dermis of skin. It includes bony scales and plates or scutes (osteoderms), finrays and antlers of fishes, some reptiles (crocodiles, turtles and tortoises) and mammals. In fishes, dermal scales become exposed due to wearing out of epidermis, and form exoskeleton.
- (3) **Endoskeleton**: Greater part of vertebrate skeleton lies more deeply, forming the endoskeleton. It develops from mesenchyme. Endoskeleton is formed by bones in vertebrates. Skeleton in different animals are as follows –

Invertebrate -

(i) Protozoa - No skeleton.

(ii) Porifera – Calcareous spicules + silicious spicules + spongin fibre in mesenchyme.

Spicules in porifera represent endoskeleton.

- (iii) Coelenterata Calcareous (corals) and chitinous (perisarc).
- (iv) Helminth No skeleton, cuticle7 present.
- (v) Annelida No skeleton, cuticle present.

In earthworm and ascaris hydrostatic skeleton is found that is fluid is filled in coelom and form turgid skeleton.

- (vi) Arthropoda Dead chitinous exoskeleton, shed at intervals, called ecdysis or moulting. Cuticle made up of non chitinous outer epicuticle and chitinous, inner endocuticle.
- (vii) Mollusca Calcareous shell, may be external or internal or absent.
 - (viii) Echinodermata Dermal calcareous plates are present.
- (ix) Hemichordates Endoskeleton in form of proboscis skeleton, pygochord.

In vertebrates exoskeleton may be epidermal or dermal.

Vertebrates: In vertebrates dermal skeleton is formed by bones. Bone is the connective tissue with intercellular spaces filled with ossein matrix composed of 25% water, 25% protein fibers, 50% mineral salts. The inner most region is full of bone marrow having various types of cells. In mammals the bone is full of haversian canals. The bones are of following types —

- (i) Cartilage bones: The bones which are formed by the ossification of preexisting cartilage are called cartilage bones or replacing bones. e.g., vertebra, Girdles, limb bones, basioccipital, supraoccipital, sphenoid, Incus, malleus, stapes.
- (ii) **Membrane or dermal bones**: The bones which are formed by independent ossification in connective tissue are called dermal, membrane or investing bones. *e.g.*, Ribs, sternum, clavicle, Nasal, vomer, palatine, maxilla.
- (iii) **Sesamoid bones**: Ossification takes place on ligament e.g., cotyloid bone of Rabbit and tendons e.g., Patella, Pisiform.

UNIVERSAL BOOK DEPOT 1960

- (iv) **Pneumatic bones**: Bones with hollow spaces containing air e.g., bones of bird, frontal, sphenoid, ethmoid, maxilla of human.
 - (v) Irregular bones : Vertebrae are irregular bone.
 - (vi) Flat bones: Cranial bone, scapula, Ribs.
 - (vii) Short bones: Carpals and tarsals.

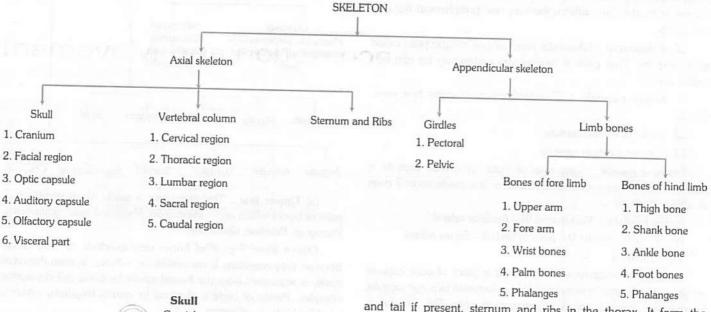

Functions of endoskeleton: Chief function of vertebrate endoskeleton can be enumerated as follows

- (i) To provide physical support to body by forming a firm and rigid internal framework.
 - (ii) To give definite body shape and form.
 - (iii) To protect delicate internal organs like brain, heart, lungs etc.

- (iv) To permit growth of huge body size (whale, elephant, extinct dinosaurs), since it is living and growing.
 - (v) To provide surface for attachment of muscles.
 - (vi) To serve as levers on which muscles can act.
 - (vii) To manufacture blood corpuscles in bone marrow.
 - (viii) To help in breathing (tracheal rings, ribs).

Endoskeleton of vertebrates

- (1) Axial endoskeleton : (Skull + Vertebral column + Sternum + Ribs)
 - (2) Appendicular endoskeleton: (Girdle + Limb bones)

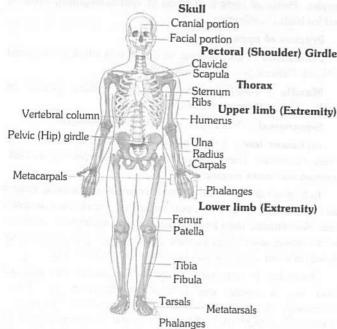

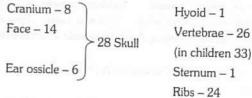

Fig: 5.5-1 Divisions of skeletal system

Axial skeleton (Human)

It occupies the body's main longitudinal axis. It includes four structure: skull in the head, vertebral column in the neck, trunk

and tail if present, sternum and ribs in the thorax. It form the upright axis of body and includes $80\ (87\ \text{in children})$ bones as follows in man –

Skull (General structure) : It is the anterior most axial skeleton. It is divisible into two main parts –

- (i) Chondrocranium (ii) Splanchnocranium
- (i) Chondrocranium: Chondrocranium is formed by (a) brain box or cranium proper and (b) two sense capsules Orbit or optic capsule (eye) and auditory or otic capsule (ear).
- (a) **Cranium proper:** It is a strong and firm bony box with a helmet-like covering over the brain, called vault of skull, and a relatively thicker and stronger floor of base upon which the brain rests. Its cavity is called cranial cavity. Size of cranial cavity averages 1475 cubic centimetres (cm³) in adult men. At about the middle of the floor of cranium, there is a large opening of cranial cavity called foramen magnum. The brain is connected to spinal cord at this foramen. Cranium proper of mammal has following distinct zones –

Occipital zone : Occipital zone has one supra-occipital
bone on dorsal side, one basioccipital on ventral side and two
exoccipital on both lateral side of foramen magnum. Foramen
magnum is present in ventral side of skull, which fits on 1st atlas
vertebra. Two occipital condyles forming dicondylic skull at the
junction of supra and exo-occipital.

Parietal zone: In the dorsal side of cranium parietal zone has three bone, that is two parietal, one inter parietal and ventral side of cranium has 3 bone i.e. one basisphenoid with pituitary foramen and two alisphenoid bone.

☐ Frontal: Frontal part of cranium has two frontal bone in dorsal side, each frontal bone has one process called supra orbital process of frontal. Two orbitosphenoid, one presphenoid bone in ventral side.

☐ Ethmoidal: Ethmoidal part has one circular plate called cribriformplate. That plate is having two perforation for exit of I cranial nerve.

(b) Sense capsule : Chondrocranium contains two sense capsule.

Optic or orbital capsule

Otic or auditory capsule

Optic capsule: One pair of optic or orbital capsule is present in frontal zone of chondrocranium. It is made up of 7 pairs of bones which are –

I - Pre frontal II - Post frontal III - Anterior orbital

IV - Posterior orbital V - Infra orbital VI - Supra orbital

VII - Lacrimal

In frog optic capsules are absent but in place of optic capsule eye-orbit are present in same position. In between two eye capsule, a separating bone is present in mammals only. This separating bone is called inter-orbital septum. This septum is absent in frog between two eye orbits.

Auditory or Otic capsule: Auditory capsule is located between occipital and parietal zone. It has two parts – Tympanic bulla and External auditory meatus. Auditory capsule in vertebrates is formed by 5 pairs of otic bones.

(I) Preotic (II) Epiotic (III) Opisthotic (IV) Sphaenotic

(V) Pterotic

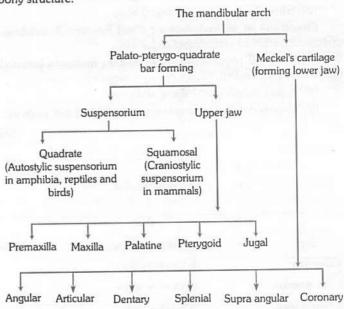

Out of these 5 pairs only I pair i.e. preotic participate in formation of auditory capsule of frog i.e. amphibian. In mammals e.g., rabbit I, II & III pair fuse to form a fusion bone called periotic, which forms the auditory capsule. In reptiles and birds (aves) all 5 pairs bone together constitute auditory capsule. Membranous labyrinth is enclosed in the preotic and tympanic bulla. Auditory capsule has two distinct part – Outer spongy part called petrous part and inner bony part called mastoid part.

(ii) Splanchnocranium: It is also known as facial. It includes following parts –

☐ Visceral skeleton: Visceral skeleton is formed by pairs of visceral arches which are —

Mandibular arch (I pair of visceral arch): It is made of two arches one is upper forming upper jaw and second is lower called lower jaw. In tadpole stage upper jaw i.e. upper part of mandibular arch is formed by the fusion of three cartilage called palatine, pterygoid and quadrate. These all fused to form palatopterygoquadrate.

Lower jaw or II part of mandibular arch is cartilagenous initially and is called Meckel's cartilage which soon changes into bony structure.

(a) Upper jaw: The upper jaw is made of 14 bones i.e. 7 pairs of bones which are – Premaxilla, Maxilla, Jugal, Squamosal, Pterygoid, Palatine, Quadrate.

Out of these 7 pairs of bones only quadrate are not visible because they constitute II ear ossicle i.e. – incus. In man the nasal cavity is separated from the buccal cavity by bone called palatine complex. Palate of birds is identical in animal kingdom, which is used for birds classification.

Process of upper jaw

Premaxilla: Nasal process on dorsal side which are covered by Nasal; Palatine process of premaxilla.

Maxilla: Nasal process of maxilla; Palatine process of maxilla; Zygomatic process of maxilla.

Squamosal: Only zygomatic process of squamosal.

(b) **Lower jaw**: It is composed of 6 pairs of bone *i.e.* 12 bones maximum. These are articular, angular, splenial, dentary, coronoid and supra angular.

In frog out of 6 pairs only 4 pairs of bones are present. Only 3 pairs form lower jaw and one pair forms I ear ossicle i.e. collumella auris. Remaining 3 pairs i.e. Angular, splenial and dentary combine to form lower jaw of frog. In mammals only one pair of bones are present of which only one pair i.e. dentary forms lower jaw.

Upper jaw in vertebrates is completely ossified with skull but lower jaw is always free from chondrocranium and hangs downwardly. A bone hangs lower jaw from upper jaw. This bone is called suspensorium. A skull in which suspensorium is formed by quadrate is called autostylic skull *e.g.*, frog skull. A skull in which suspensorium is formed by squamosal is called craniostylic skull *e.g.*, rabbit skull (all mammal).

Hyoid arch (II pair of visceral arch): It is also one pair which is called Hyoid proper and Hyomandibular.

UNIVERSAL BOOK DEPOT 1960

(a) **Hyoid proper**: It is a horse-shoe shaped bone in our neck between lower jaw and sound box or larynx. It is not articulate to any bone but is simply suspended from temporal bones by means of ligament. It consists of an elliptical main part or body and two processes on each side of body, called greater

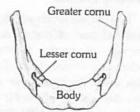

Fig. 5.5-2 : Human hyoid bone viewed from above

and lesser cornua. It supports our tongue and provides insertion to some tongue muscles. In colloboration with branchial arches forms hyoid apparatus in terrestrial vertebrates. It is absent in fishes because branchial arches form gill rackers which support gills.

(b) Hyomandibular: It is second part of hyoid arch which constitutes ear ossicles in vertebrate. In frog hyomandibular forms stapidial plate which is Ilear ossicle which is dot or lid like bone. In rabbit hyomandibular forms stapes which is III ear ossicle. That is stirrup like bone.

Table: 5.5-1 Ear ossicles

1	II	III	
Malleus	Incus	Stapes	
Articular	Quadrate	Hyomandibular	
Hammer	Anvil	Stirrup	

Branchial arches (III to VII pair of Visceral arches): These are five pairs, which constitute III to VII pair of visceral arches. These constitute gill racker in fishes but terrestrial animals then form hyoid apparatus in collaboration with hyoid proper. Five pairs of branchial arches are as follows –

- (a) III pair ceratohyle.
- (b) IV pair i.e. is epihyal.
- (c) V pair i.e. is stylohyal.
- (d) VI pair i.e. tympanohyal.
- (e) VII pair i.e. thyrohyal.

Skull of man

In man however the skull remain erect at top of vertebral column because of perfectly erect posture of body it is divisible into the large and hollow cranium and the facial region together protects and support some useful organ for vision, taste, smell, hearing and equilibrium.

(1) **Cranium (Brain case) :** Cranium stabilize the position of brain. In skull of man all eight bones are articulated with each other to form the cranium as follows –

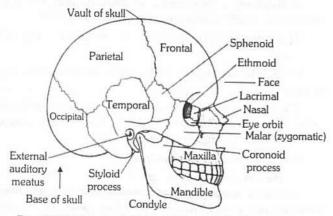

Fig: 5.5-3 Human skull viewed from right side

Table: 5.5-2 Bones of cranium

Table : 5.5-2 Bones of cranium						
Name	No.	Description				
Frontal	1	Forms the forehead (anterior or front part of the top of cranium) and some upper parts (roofs) of eye orbits or sockets and nasal cavities. A newborn infant displays a faint suture in midline of frontal, indicating that adult frontal is actually formed of two completely fused frontal. Frontal suture between two frontal disappear by age 6 years. If persists throughout life referred as metopic sutures.				
Parietals	2	Articulated to and situated just behind frontal. Form the main parts of bulging top and sides of cranium.				
Occipital	1	Articulated to and situated just behind parietals. Forms posterior (back) and lower (base) parts of cranium. Foramen magnum is a large perforation in this bone. On each side of the foramen, the occipital bears a prominent elevation called occipital condyle. The condyles articulate the skull with first vertebra (atlas). Thus, human skull is dicondylic.				
Temporals	2	Form lower parts of right and left sides of cranium, as well as, the floor of cranial cavity. These house structures of internal and middle ears and form a part of external auditory meatus. The middle ear of each side encloses the three small ear ossicles – malleus, incus and stapes. The mastoid process with mastoid air cells in adult.				
Sphenoid	1	A typically butterfly-shaped bone that forms the middle and anterior parts of base of cranium in front of occipital in the middle and temporals on the sides. It articulates with all skull bones, keeping these firmly together. It also forms parts of lateral walls and floors of eye orbits. Sphenoid with sella turcica depression for pituitary body.				
Ethmoid	1	A small, irregular bone in front of sphenoid and behind nasal bones. It fashions the front (anterior) extremity and closer of cranial cavity. It also contributes to the architecture of eye orbits and proximal parts of nasal chambers.				

(2) The facial region: This is the front or anterior part of our skull comprising of 14 bones as follows:

Table: 5.5-3 Facial bones

Name	No.	Description
Nasals	2	Small, oblong bones in middle of upper part of face, forming proximal part of the bridge of our nose. The remaining, lower part of our nose is formed of cartilage.
Inferior nasal conchae (Turbinates)	2	Two highly coiled, scroll-like processes of ethmoid bone, called conchae project into each nasal cavity from lateral wall of the proximal bony part of concerned nasal chamber. One ethmoidal concha is superior (uppermost). The other one is called middle concha, because it is followed by a thin, separate scroll-like bone which is named inferior nasal concha or turbinate.
Vomer	1	A thin, elongated, platelike bone, forming a part of the septum which separates the two nasal cavities.
Lacrimals	2	Small and thin, finger-shaped bones, each located in front part of the medial (inner) side of corresponding eye orbit, these form a part of the passages of corresponding tear ducts.
Zygomatics (Malars)	2	Cheek-bones; form the prominences of our cheeks and parts of the floor and side walls of eye orbits.
Palatines	2	L-shaped bones that form the back (posterior) part of our hard palate (roof of mouth). Also contribute to the framework of nasal cavities and floor of eye orbits.
Maxillae	2	Large, upper jaw bones that form the major part of our face and upper jaw. Comprise entire front (anterior) part of our hard palate. Also contribute to the architecture of eye orbits and nose. Bear the teeth of upper jaw.
Mandible	1	Largest bone of our face, and strongest of all bones of the body. Forms entire lower jaw and bears all lower jaw teeth. Articulated with temporal bones of skull. Only skull bone that moves.

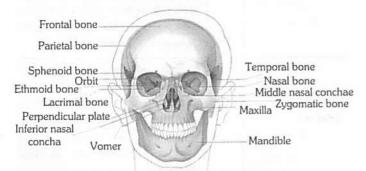

Fig: 5.5-4 Human skull viewed from the front

Vertebral column

It is our backbone which extends in the mid axis of the back (posterior) part of our trunk from head to the lower (inferior) extremity of trunk. Vertebral column of vertebrates is a modification of notochord. Together with the stemum and rib, it forms the supporting frame work of our trunk. It supports and rotate the head, suspends the viscera, protect vital organs, provides attachment to limb girdles, facilitates some movement of the trunk and houses the spinal cord. Vertebral column make two-fifth of total weight of body. The length of human vertebral column is 71 cm. (28 Inc.) in adult male and about. 61 cm (24 inches) in an average adult female.

Curvatures of vertebral column: In a foetus, there is only a single anteriorly concave curve, in adult there are 4 curves like, cervical, thoracic, lumbar, and sacral. Cervical and lumbar are anteriorly convex, while thoracic and sacral are anteriorly concave. At approximately 3rd month after birth, when an infant begins to hold its head erect, cervical curves develops. Later, when the child sits up, stands, and walks, the lumbar curves develops. The thoracic and sacral curves retains anterior concavity of foetus thus are called 'Primary curves'. The cervical and lumbar curves are modification of the original foetal curves, and are called as "Secondary curves".

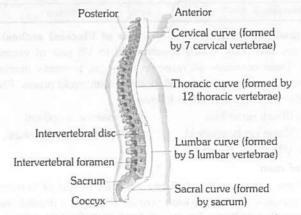

Fig: 5.5-5 Right lateral view showing four normal curves

The curves of vertebral column are important because they increases its strength, help to maintain balance in upright position absorb shock during walking and running and help to protect the column from fracture. Certain abnormalities of curvature are :

- (i) **Kyphosis**: Exaggeration of thoracic curve, resulting in "round-shouldered" appearance, also called hunch back.
- (ii) **Lordosis**: An exaggeration of lumbar curve, also called swav back.
- (iii) Scoliosis: An abnormal lateral curvature in any region of spine.

The vestigeal notochord called nucleus pulposus is found in intervertebral disc. Inter-vertebral disc is fibro cartilagenous disc present between centrum of vertebrae.

Structure of Typical vertebrae

(1) Neural arch: It arises from the dorsal side of the centrum and encloses a neural canal for the spinal cord. The arch may be produced into a dorsal process, the neural spine, which may be elongated pointed or flattened and directed upwards or backwards.

- (2) Transverse processes: These are lateral extension of neural arch and centrum. There may be two types of these processes a more dorsal diapophysis arising from the base of neural arch and a lateral parapophysis arising from the side of the centrum.
- (i) Diapophysis (dia- two; apo- from; physis growth): These paired processes are directed differently and provide attachment to the tubercular processes of ribs. They are commonly known as transverse processes and are found in amphibians and other higher vertebrates.
- (ii) Parapophysis: These paired outgrowths are similar to diapophysis and are common in fishes.
- (iii) Zygapophysis: These are paired and flat articular surfaces, which check the dislocation of the vertebrae. These are the only structures which enable to identify the anterior and posterior faces of vertebra.

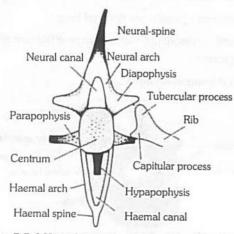

Fig: 5.5-6 Hypothetical typical vertebra (front view)

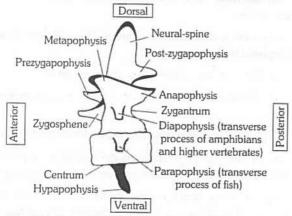

Fig: 5.5-7 Hypothetical typical vertebra (side view)

- (iv) Hypapophysis: It is a mid-ventral process which arises from the centrum. It may be directed forwards or backwards as in certain reptilian, avian and mammalian vertebrae.
- (v) Metapophysis: These are paired swellings or out growths having broad base and arising from just above the prezygapophyses. They are directed forwards and upwards, but their articular facets look slightly downwards. They are found in certain mammalian vertebrae.

- (vi) Anapophysis: These are paired, slender and short processes which arise just below the postzygapophysis. Their articular facets look-slightly upwards and receive for the matapophysis.
- (3) **Heamal arch**: It surrounds the haemal canal which allows the blood vessels of the tail region to pass. It may be produced into a haemal spine below *e.g.*, in fishes. The haemal arch of the caudal vertebrae of reptiles is called chevron bone. It is usually Y-shaped.
- (4) **Centrum**: The part of vertebra attached to second by centrum. On the basis of centrum vertebrae may be of following type—
- (i) **Procoelous-vertebrae**: Anterior end is concave and posterior end is convex. *e.g.*, 2nd to 7th vertebra of frog. Reptile (Lizard)
- (ii) **Ophisthocoelous vertebrae**: Anterior end is convex and posterior end is concave. *e.g.*, Fishes, snake and crocodile only.
- (iii) **Heterocoelous vertebrae**: Anteriorly convex from dorsal to ventral and concave from side to side. On posterior side concave from dorsal to ventral and convex from side to side (saddle shaped). *e.g.*, Birds.
- (iv) **Acoelous vertebrae**: Also known as Amphiplatyon. No cavity in centrum so centrum is flat. *e.g.*, Mammals (man, Rabbit).
- (v) **Amphicoelous vertebrae**: Cavity present on both side of centrum. *e.g.*, VIIIth vertebra of frog. All veretebrae of scoliodon (Dog fish)
- (vi) **Amphidicondylar (Biconvex)**: Biconvex, condyle on both side. e.g., IXth vertebra of frog.

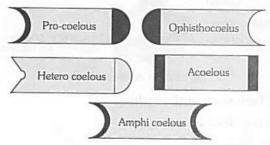

Fig: 5.5-8 Types of Centrum

Vertebral column of man: Made up of pieces of bones known as vertebrae. Vertebrae of man are accelous *i.e.* Centrum is flat and without cavity (Amphiplatyon). Vertebral column is also known as spinal column or backbone.

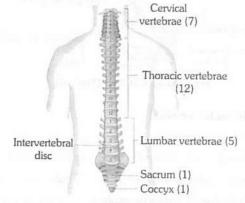

Fig : 5.5-9 Anterior view showing regions of the vertebral column

- (1) Atlas vertebra
- (i) First cervical vertebra.
- (ii) Body is formed of vertebral arch transverse process.
- (iii) It supports the globe of the head like the earth by the atlas (super man).
 - (iv) Centrum is absent.
 - (v) Neural spine absent.
 - (vi) Transverse process are long with transverse foramen.

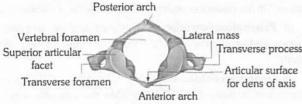

Fig: 5.5-10 Atlas

- (2) Axis vertebra
- (i) Second cervical vertebra.
- (ii) Centrum acoelus.
- (iii) Odontoid process or dens present, which is modified centrum of Atlas.
- (iv) It is pivot for rotation of atlas and head around odontoid process. Transverse process small.

Fig: 5.5-11 Axis-vertebrae

- (3) Typical cervical vertebra
- (i) Long neural spine.
- (ii) Centrum acoelus.
- (iii) Transverse process are large.
- (iv) Vertebrarteal canals present.
- (v) Vertebrarteal canals also known as foramina transversaria.

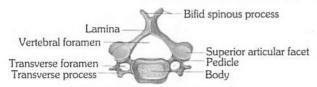

Fig: 5.5-12 Cervical (Typical)

- (4) Thoracic vertebra
- (i) Centrum acoelus.
- (ii) Neural canal is formed by union of two neural arches.
- (iii) Neural spine is flat & long directed backward.
- (iv) Club shaped transverse process.
- (v) Neural arch with superior articular process.

(vi) Two demifacets for articulation of head of a rib are sent.

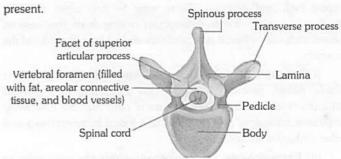

Fig: 5.5-13 Thoracic-vertebrae

- (5) Lumbar vertebra
- (i) Centrum acoelus.
- (ii) Neural spine well developed.
- (iii) Transverse process are thin and long.
- (iv) Small accessory process present near the root of each transverse process.
 - (v) It is the largest vertebrae.

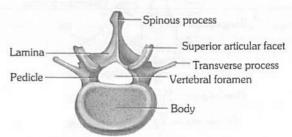

Fig: 5.5-14 Lumbar-vertebrae

- (6) **Sacrum**: It is a triangular bone formed by fusion of 5 sacral vertebra.
- (i) Fusion normally begins between 16 to 18 years of age and is completed by 30 yrs. of age.
 - (ii) Serves as strong foundation for pelvic girdle.
- (iii) Sacrum with 4 pairs of anterior and posterior sacral foramina.
 - (iv) Lateral part of sacrum articulate with ilium of hip bone.
- (v) Female sacrum is shorter, wider and more curved between S_2 and S_3 the male sacrum is longer, narrower, and less curved.
- (vi) In birds some of the vertebrae are fused to form synsacrum. [Last thoracic+ Lumbar+ Sacral+ One or two caudal]
 - (7) Coccyx
 - (i) It is formed by fusion of four coccygeal vertebrae.
 - (ii) It is last section of backbone.
 - (iii) It is small triangular bone.
- (iv) Two coccygeal cornua project upto articulate with sacral cornua
 - (v) Rudimentary transverse process.

(vi) Fusion generally occurs between 20 and 30 years of age.

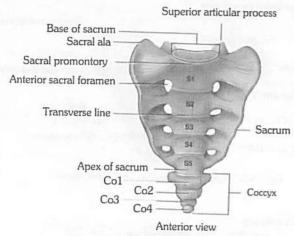

Fig: 5.5-15 Human sacrum and coccyx

Thoracic basket

(1) Ribs

Structure: The ribs are curved bars, which movably articulate with the thoracic vertebrae at the back and while with the sternum in front all collectively forming a bony cage, the thoracic basket. These are 12 pairs of ribs. The upper seven pairs of ribs are attached in front directly to the sternum by hyaline cartilage. These are called true rib. The next three pairs of rib costal cartilage attach indirectly to sterum. They are termed false ribs. The lower two pair of ribs are free in front they are known as floating ribs. Tenth rib is also usually floating in Japanese and some other people.

A rib consists of two parts, Vertebral and Sternal. The vertebral part is long and bony. It articulate with the thoracic vertebrae by 2 facets, the capitulum and tuberculum, (Ribs of mammal and birds are bicephalous) in the first nine ribs and by a single facet, the head in the remaining vertebrae. The sternal part is short and cartilaginous. It articulate with the sternum or sternal part of its upper rib.

Human thorax is wider from side to side then from front to back. This is an adaptation for the up right posture of the body. It help to maintain equilibrium. In birds an uncinate process is present in ribs for muscles attachment.

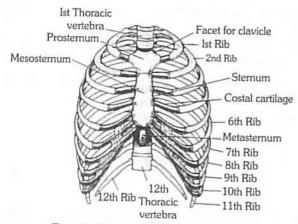

Fig: 5.5-16 Bones of thorax (front view)

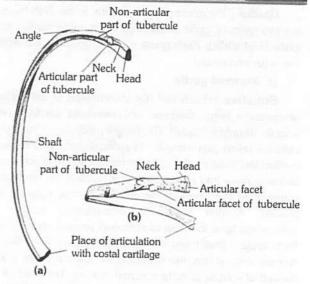

Fig : 5.5-17 A typical rib of left side (a) Inferior aspect; (b) Posterior aspect

Function: The ribs serve three important functions -

- (i) They protect the heart, large blood vessels and lungs.
- (ii) They bear respiratory muscle (external and internal intercostal muscle).
 - (iii) Lower two pair of ribs protect the kidney. (11th and 12th)
 - (2) Sternum

Structure

- (i) It is a bone of chest
- (ii) It is absent in fish, Turtle.
- (iii) It is associated with pectoral girdle in amphibia.
- (iv) In man it is made up of cervical manubrium (presternum), mesosternum and xiphoid process (Metasternum).
 - (v) In male it is nearly 17 cm long.
 - (vi) Manubrium is broad and thick.
 - (vii) Mesosternum is made up fine sternebrae.
- (viii) Metasternum is represented by xiphisternum which is smallest broad and thin. In mammal a cartilagenous plate is attached with xiphisternum known as xiphoid cartilage (hyaline).
 - ☐ Sternum = manubrium + 5 sternebrae + xiphisternum.

Function: The sternum has two function -

- (i) It takes part in the formation of the protective thoracic basket.
 - (ii) It plays a role in the respiratory mechanism.

Appendicular skeleton

It forms the bony frameworks of limbs and their supporting girdles, and includes 126 bones as follows –

1. Upper extermities	2. Lower extermities
(i) Pectoral girdle—Clavicle (2)	(i) Pelvic girdle 2
Scapula (2)	
(ii) Upper limbs (arms) 60	(ii) Lower limbs 60

Girdles: The girdle give articulation to the limb bones. There are two types of girdle pectoral girdle (shoulder girdle) and pelvic girdle (Hip girdle). Each girdle is made up of similar right and left halves (os innominate).

(1) Pectoral girdle

Structure: Each half (Os innominate) of the girdle mainly comprises a large, flattened and triangular cartilage bone, the scapula (shoulder blade). The broader side has a narrow strip of cartilage called suprascapula. The dorsal surface of scapula has a median longitutinal ridge called acromian spine, which successively becomes more and more prominent towards the narrower end of scapula and then, projects beyond this end as a distinct acromian process. Another prominent metacromian process projects horizontally from the base of acromian process. At its narrow end, the scapula is itself fused with an inwardly bent, knob like coracoid process. A deep, cup like concavity the glenoid cavity is located at the end of scapula close to coracoid process. The head of humerus (bone of upper arm) fits into this cavity. Another component of each half of pectoral girdle is a long and slender, rod-like membrane bone the clavicle, articulated with the acromian process. The other end of clavicle is connected with pre sternum by means of an elastic ligament. Clavicle is also called collar bone.

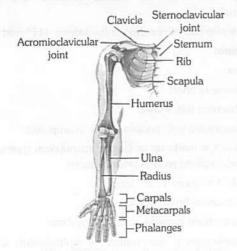

Fig: 5.5-18 Scapula-pectoral girdle

Function: The pectoral girdle serves two functions -

- (i) It provides articulation to the arm bones.
- (ii) It affords attachment to certain muscles of the arm.
- (2) Pelvic (Hip) girdle

Structure: It is located in the lower part of the trunk. It consists of 3 bones – upper ilium, lower ischium and inner pubis, fused to form a stout hip bone, the innominate. Ventral wall of pubis has a small bone called cotyloid. Acetabulum is formed by ilium, ischium and pubis, but in mammals pubis is replaced by cotyloid bone. Pubic symphysis is present in mammals. Below the acetabulum, the innominate has a large oval gap, the obturator foramen (ischio-pubic foramen). The two innominate bones and sacrum together form a sort of bowel, the pelvis, that supports the lower abdominal viscera. This is also an adaptation for upright posture of the human body. The female pelvis is larger and has a broader front and larger bottom opening than the male pelvis. This

is an adaptation for childbirth. In man ischial tuberosity or siting bone is present in ischium.

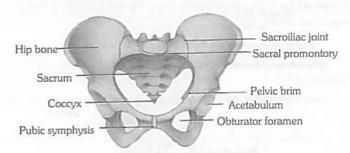

Fig: 5.5-19 Man-male pelvis (Anterior view)

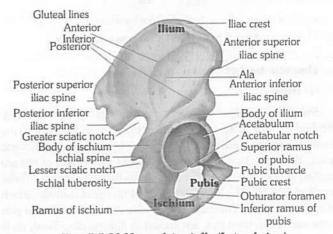

Fig: 5.5-20 Man-pelvic girdle (Lateral view)

Functions: The pelvic girdle serves the following functions -

- (i) It provides articulation to the bones of the leg.
- (ii) It contributes to the formation of a bowel for the support and protection of abdominal viscera.
 - (iii) It transfers the weight of the body to the leg.
 - (iv) It provides the attachment to certain leg muscles.
 - (v) Support vertebral column.

Limb bones: Limb are of two types fore limb and hind limb.

(1) Bones of fore limbs

Structure

- (i) Humerus or arm bone or bone of upper arm, is longest and largest bone of upper limb.
- (ii) It articulates proximally with scapula and distally at the elbow with both ulna and radius.
- (iii) Humerus proximal end with greater and lesser tuberosity tubercle.
 - (iv) Both radius and ulna with nutrient foramina.
 - (v) Radius present towards thumb side.
 - (vi) Ulna present towards little finger side.
- (vii) It includes Humerus + Radius & ulna + Carpals + Meta carpals + Phalanges.
- (viii) Humerus is characterised by the presence of deltoid tuberosity for the attachment of muscles.

UNIVERSAL BOOK DEPOT 1960

- (ix) Distal end of humerus at the elbow joint is like pully and called trochlea. Its groove is called olecranon fossa whose basal part is marked by a supratrochlear foramen for the passage of brachial artery and nerve.
 - (x) Humerus is characterised by arterial foramen.
- (xi) Head of the humerus articulate with glenoid cavity of pectoral girdle.
- (xii) Radius is smaller and ulna is larger, were bones of fore arm.
- (xiii) Styloid process is present in distal end of ulna and radius both.
- (xiv) Olecranon process is present in ulna. Proximally, which forms prominence of elbow.
- (xv) Trochlear notch is formed by ulna which is also known as sigmoid notch.
- (xvi) Carpals or wrist bone are eight in number, joined to one another by ligaments. Carpals are arranged in 2 rows, with 4 bones in each row.
- (xvii) Metacarpals are five in number, and phalanges are fourteen, phalanges formula = 2, 3, 3, 3, 3.

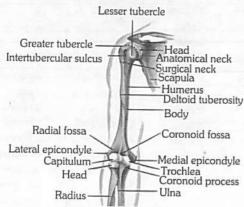

Fig: 5.5-21 Humerus (Anterior view)

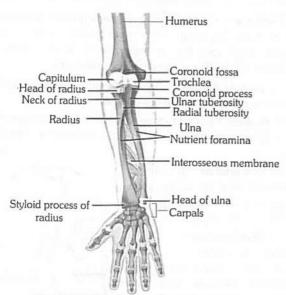

Fig: 5.5-22 Radio-ulna (Anterior view)

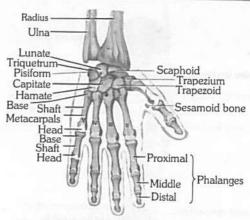

Fig: 5.5-23 Hand (Posterior view)

Special features: In the human arm, (i) The joints are more movable than in the forelimbs of animals (ii) Metacarpals form a wide palm and (iii) Thumb is opposable. The differences in structure are correlated to the differences in function. Animals use their forelimbs mainly for locomotion whereas man uses the arms for work (grasping).

Function: Bones of the arms provide strength to make the arms effective in working with them.

(2) Bones of hind limbs

Structures

- (i) It includes Femur + Tibia and Fibula + Tarsals + Metatarsals + Phalanges
 - (ii) Fovea capitis is depression in head of femur.
 - (iii) Femur is longest and strongest bone of body.
 - (iv) Femur is known as bone of thigh
- (v) Greater trochanter, lesser trochanter $3^{\rm rd}$ trochanter are present in femur, of thigh and buttock muscles.
 - (vi) Patellar groove is found in distal end of femur.
 - (vii) Fibula is smaller and associated with knee joint.
- (viii) Tibia is larger, also called shin bone. It bears a weight of body.
 - (ix) Tarsal bones are seven.
 - (x) Metatarsals are five.
 - (xi) Phalanges are fourteen.
 - (xii) Phalanges formula = 2, 3, 3, 3, 3
 - (xiii) Patella form knee cap.
- (xiv) Patella is formed by sesamoid bone. Fabella also example of sesamoid bone.
 - (xv) Thumb of foot is called hallux.
- (xvi) Ankle bones have 7 tarsals and arranged in two rows. The first row have talus and calcaneus and second row with cuboid, Navicular, and I, II, III cuneiform.
- (xvii) Nutrient foramen present in Tibio fibula bone. Tibia fibula is longest bone in frog.

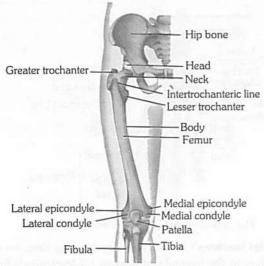

Fig: 5.5-24 Femur (Anterior view)

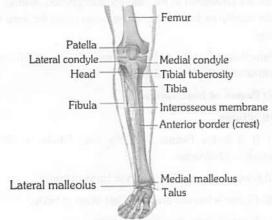

Fig: 5.5-25 Tibia-fibula (Anterior view)

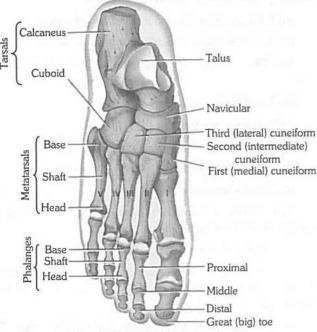

Fig: 5.5-26 Foot (Inferior view)

Special features: All the bones of the legs are more massive than the bones of the arms because the legs alone support the body on the ground and are used in locomotion. The broad feet provide an additional stable support in the upright posture.

Function : The bones strengthen the legs to bear body weight, to balance the body while standing and to aid in locomotion.

Joints

There are many articulations or joints present in the skeleton. Joint or articulation is a point of contact between bones. Joints are classified based upon their structure and the kinds of movements which they permit. Three main types of joints are –

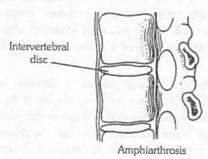

- (1) **Immovable joints (Synarthrosis) :** No joint cavity, no movement possible. These joints include –
- (i) **Sutures**: Found between skull bones, sutures are fixed or fibrous joints, articulating bones are held together by white fibrous tissue.

 Suture
- (ii) Gomphosis: It is a type of fibrous joint in which cone shaped peg fits socket. Teeth in mandibles, and maxillary bones.
- (iii) **Syndesmosis**: It is type of fibrous joint with more fibrous tissue than sutures. *e.g.*, distal articulation between tibia and fibula.

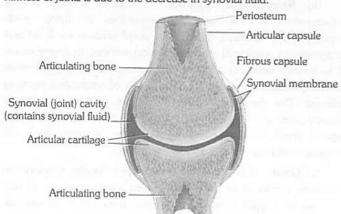

UNIVERSAL BOOK DEPOT 1960

(2) Imperfect joints (Amphiarthrosis) slightly movable: Joints in which synovial cavity is absent. Permit a small amount of movement. Fibrocartilage is placed between the bones. These are cartilaginous joints e.g., Pubic symphysis, between bodies of the vertebrae, between the manubrium and the body of sternum, sacroilliac joint in frog.

(3) **Perfect joints (Diarthrosis)** freely movable: Synovial cavity and ligaments are present. These are typical joints having articulate surface and synovial capsule. Synovial fluid act as a grease in the joint e.g., Joints of elbow, ankle, wrist, hip, knee. Articular cartilage covers the surface of articular bones. Articular cartilage of synovial joint is hyaline cartilage. Synovial joints are surrounded by tubular articular capsule. The articular capsule consists of two layers, outer fibrous capsule and inner synovial membrane. The synovial membrane secretes synovial fluid which lubricates and provides nourishment to articular cartilage. In old age stiffness of joints is due to the decrease in synovial fluid.

Typical synovial joint (Frontal section)

(i) Ball and socket joint: Also known as enarthrosis. Ball of one bone articulate in socket of another bone. e.g., head of humerus and glenoid cavity of pectoral girdle, femur and acetabulum of pelvic girdle, joint between incus and stapes.

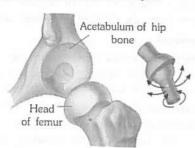

Fig: 5.5-27 Ball-and-socket joint between head of the femur and acetabulum of the hip bone

(ii) Hinge joint: Also known as gingulum. Movement is possible in one direction only. e.g., Joint of malleus and incus, knee joint, elbow joint, articulation joint of lower jaw, joint of phalanges of digits.

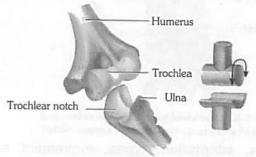

Fig: 5.5-28 Hinge joint between trochlea of humerus and trochlear notch of ulna at the elbow

(iii) Pivot joint: Also known as rotatoria and helps in turning movement. One bone is fixed and second articulate. e.g., Atlas and axial of skull rotate with axis vertebra also known as atlanto axial joint.

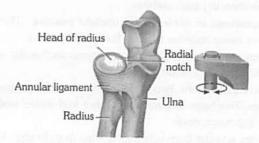

Fig: 5.5-29 Pivot joint between head of radius and radial notch of ulna

(iv) **Gliding joint**: Also known as arthrodial, limited movement in all direction. *e.g.*, Tarsals bones of ankle zygapophysis of vertebrae, Radius and Ulna.

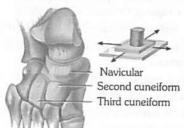

Fig: 5.5-30 Gliding joint between the navicular and second and third cuneiforms of the tarsus in the foot

(v) **Saddle joint**: It is ball and socket like joint but not developed fully. e.g., metacarpal of thumb, and carpals of hand.

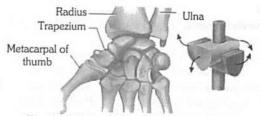

Fig: 5.5-31 Saddle joint between trapezium of carpus (wrist) and metacarpal of thumb

(vi) Condyloid joint: Also known as ellipsoidal joint is biaxial where oval condyle of one bone fits into an elliptical cavity of another bone. e.g., joint between radius and carpals at wrist.

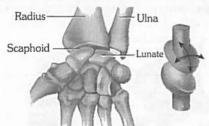

Fig: 5.5-32 Condyloid joint between radius and scaphoid and lunate bones of the carpus (wrist)

Characters, adaptation, types, movement and disorder of bones

- (1) Characteristics of female's skeleton: In female's skeleton, (i) skull is lighter, (ii) shoulders are narrower (iii) sacrum is shorter but wider, (iv) pelvis is wider, has a broader front and larger bottom opening to facilitate child birth, and (v) coccyx is more movable than in male's skeleton.
- (2) Adaptations in skeleton for upright posture: Human skeleton shows many adaptive features for upright posture –
- (i) Foramen magnum is directed downward so that the head may rest vertically on the vertebral column.
- (ii) Four curves in the backbone keep the centre of gravity near the heels. This helps to maintain balance and makes walking erect on two legs much easier.
- (iii) Thorax is wider from side-to-side than from front-to-back. This helps to maintain equilibrium.
 - (iv) Bowel-like pelvis supports the lower abdominal viscera.
- (v) Metacarpals form a wide palm and the pollex is opposable. This make the hand a grasping organ to work with it.
- (vi) Leg bones are stronger than the arm bones as the femur carry the entire weight of the body in locomotion.
 - (vii) Broad feet provide stability in the upright posture.
- (viii) The arches of the feet enable the body to move with a degree of springiness.
 - (ix) Increased mobility of the neck to see all round.
 - (x) Increased skeletal height provides greater range of vision.
- (3) **Types of bones :** Bones are divided into 4 categories regarding their size and shape –
- (i) **Long bones**, e.g., humerus of upper arm, radius and ulna of forearm, femur of thigh, and tibia and fibula of leg.
- (ii) **Short bones**, *e.g.*, metacarpals of palm and metatarsals of foot, phalanges of fingers and toes.
- (iii) Flat bones, e.g., scapula of shoulder girdle, sternum, cranial bones.
- (iv) **Irregular bones**, e.g., vertebrae, carpals of wrist and tarsals of ankle.
- (4) Bone movement: Movements of bones occur only at the joints. The movements are brought about by contractions of skeletal muscles inserted into the articulating bones by firm cords of white fibrous tissue called tendons. Cords of yellow elastic tissue, termed ligaments, stabilise the joints by holding the articulating bones together.

- (5) **Disorder of skeleton and joints :** Any violent movement, such as jump, fall or knock, may cause injury to the skeleton. The injury can be of 5 types sprain, dislocation, fracture, arthritis and slipped disc.
- (i) **Sprain**: Sprain refers to injury to a joint capsule, typically involving a stretching or tearing of tendons or ligaments. Unfortunately, both these structures have much poorer regenerative power than bone, and once stretched often remain weak. Sprain is often considered a minor disorder, but it may become chronic.
- (ii) Arthritis or Aching Joints: Arthritis refers to inflammation of the joints. It is a common disease of the old age. Its common symptoms are pain and stiffness in the joints. It has many forms. Three more common forms are described here – osteoarthritis or degenerative arthritis, the rheumatoid arthritis and gout.
- (a) Osteoarthritis: Secretion of the lubricating synovial fluid between the bones at the joint stops. The smooth cartilage covering the ends of the bones at the joint wears out due to years of use and is replaced by uneven bony spurs. The joint becomes inflamed, its movement becomes painful, and its function is diminished. Such a stiffness or fixation of a joint is also called ankylosis. The condition of osteoarthritis is more or less permanent. It is common in old persons, mainly affecting weight bearing joints.
- (b) **Rheumatoid arthritis**: It is a chronic painful inflammation of the synovial membranes of many joints simultaneously. It usually starts in the small joints in the hand and progresses in centripetal and symmetrical manner. In severe cases, it eventually results in crippling deformities. There may be other manifestations such as fever, anaemia, loss of weight and morning stiffness. The rheumatoid arthritis involves erosion of joints. It usually starts at the age of 20-40 years, but may begin at any age. It affects the women more often than the men. Rest and exercise under medical advice may give relief.
- (c) **Gout**: It is an inherited disorder of purine metabolism, occurring especially in men. Body forms excess amounts of uric acid and the crystals of sodium urate are deposited in the synovial joints, giving rise to severe arthritis. It generally affects one or two joints only. It is very painful, particularly at night, and makes movement difficult. Redness and tenderness may be noticed in and about the affected joint. Gout generally affects the great toe. Occurrence of gout is related to diet. Persons suffering from gout should avoid meat. There is no cure for arthritis. However, pain relieving (analgesic) drugs are available to give comfort.

(iii) Osteoporosis

(a) **Meaning**: Osteoporosis is reduction in bone tissue mass causing weakness of skeletal strength (*G.osteon* = bone, *poros* = pore, *osis* = condition). It results from excessive resorption of calcium and phosphorus from the bone. There is relatively greater loss of trabecular bone than of compact bone. This leads to vertical compression, or crush fracture, of the vertebrae (which consist primarily of trabecular bone), and fracture of the neck of the femur (which has considerable trabecular bone).

- (b) Causes: Osteoporosis occurs in postmenopausal women and elderly men. It may result from defective intestinal calcium absorption and menopause. Possible environment factors include smoking, excessive drinking, and decreased exercise. Osteoporosis is more common in women than in men, and in older than in middle-aged persons.
- (c) Symptoms: Symptoms of osteoporosis are pain in the bone, particularly the back, and vertebral crush, usually in weight bearing vertebrae (thoracic-8 and below).
- (d) Prevention: Preventive measures in high-risk patients include supplementary calcium and exercise, and, in postmenopausal women, estrogen replacement therapy. Supplementary calcium and sex hormones decrease bone resorption and may arrest or reduce disease progression.
- (iv) **Dislocation**: Dislocation is displacement of bones from their normal positions at a joint, for instance, slipping out of the ball of one bone from the socket of another bone into which it is fitted. Dislocation is accompanied by pulling or even tearing of the ligaments. Dislocation also tends to become chronic.
- (v) Slipped disc: Slipped disc is a displacement of vertebrae and the intervertebral fibrocartilage disc from their normal position. It may result from mechanical injury or defects of ligaments holding the vertebrae together.
- (vi) **Fracture**: Fracture is a break of a bone. Fracture occurs rarely in children. The bones of children have a large quantity of organic matter and are, therefore, very flexible and less likely to break. With advancing age, mineral matter (calcium phosphate) is deposited in the bones. This decreases the organic matter, making the bones hard and brittle. Thus, old people are more liable to fracture of bones. Bones fractures are of many types –
- (a) Green-stick fracture: Fracture in which the bone is partially bent & partially broken, as when a greenstick breaks, occurs only in children.
- (b) **Simple or complete fracture**: Bone breaks completely into two parts which remain close to each other.
- (c) Comminuted fracture : Bone breaks into more than two pieces (smaller fragments between two main fragment,
- (d) **Compound fracture**: Bone breaks completely but a fragment pierces out through the skin.
- (e) **Evulsive fracture**: A small piece breaks off fully from the bone but remains attached to the ligament. Fractures need surgical treatment for healing and should be promptly and properly attended to.

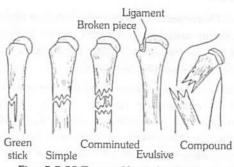

Fig: 5.5-33 Types of bone fracture

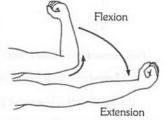

- (vii) Bursitis: Bursitis in inflammation of the bursae present in the joints. It is caused by physical injury or constant pressure on a single joint for a long time.
- (viii) Osteomyelitis: It is the inflammation of bone due to pus producing organism. It may remain localised or spread inside involving various parts including bone marrow.

Body muscles

In the body of all the multicellular animals muscles are found. The movement of the body takes place by these muscles. If the muscles become weak, the functioning of the body become difficult. The muscles are capable of contraction and relaxation, hence these are elastic.

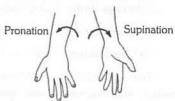

A muscle can pull a part of the body by its contraction (shortening). It cannot push that part by relaxation (elongation). Hence, the muscles are typically arranged in antagonistic (opposing) pairs, one muscle moves a body part in one direction by its contraction and the other muscle moves that part in the opposite direction by its contraction. Of course, when one muscle contracts, its opposing muscle relaxes. The principle of antagonistic muscles is true of both vertebrate as well as invertebrate muscles. Animal movements depend upon interaction of muscles and skeleton.

- (1) Action of body muscles: As mentioned above, the body muscles are arranged in antagonistic (opposing) pairs. One muscle of a pair moves a body part in one direction and the other in the opposite direction. For example, the muscle named biceps brings the forearm toward the upper arm, and the muscle called the triceps moves the forearm away from the upper arm. When biceps contracts to cause movement, the triceps relaxes to allow that movement to occur and vice versa. Similar pairs of opposing flexor and extensor muscles occur at the wrist, ankle and knee. The type of movement that results from the contraction of a muscle depends entirely upon the way the muscle is attached to the levers of the skeleton.
- (2) Classification of body muscles: According to the type of motion they cause, the muscles are divided into the following types. The muscles that act together to produce a movement are called synergists and the muscle that act in opposition to each other are antagonists. The muscles that act most powerfully during any given movements are called prime movers.
- (i) Flexor and Extensor: Muscles that bend one part over another joint is called flexor. Extensor muscle is antagonist of flexor muscle. The contraction of an extensor extends a joint by pulling one of the articulating bone apart from another.

(ii) **Pronator and Supinator :** The contraction of a pronator rotates the forearm to turn

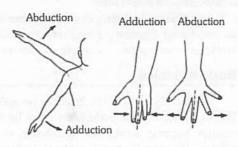

rotates the forearm to turn the palm downward or backward. Supinator is antagonist of pronator. A supinator contracts to rotate the forearm and thus to make palm face upward or forward.

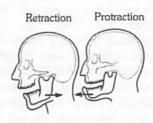

(iii) Abductor and Adductor: An abductor contracts to draw a bone away from the body midline. Muscle that brings the

limb away from midline is called abductor. An adductor draws a bone towards the body midline. Muscles that brings the limb towards midline is called

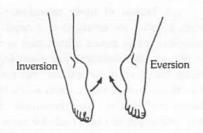

adductor. Abductor muscle is antagonist of adductor muscle. Abduction is elevation and adduction is depression.

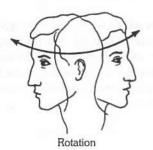

(iv) Protractor and Retractor: Protractor muscle pulls the lower jaw, tongue and the head forward. Retraction is opposite to protraction. Retractor muscle draws the lower jaw, tongue and the head backward.

(v) Inversion and Eversion: Turning of feet so that the soles face one another in inversion. Eversion is the opposite of inversion. In this movement, the soles of the feet face laterally.

(vi) Rotation: Rotation is a term that indicates the partial revolving of a body part on the part's long axis.

(vii) Arrector: Raises hairs of skin.

(viii) Levator: Elevates a part of body.

(ix) Depressor: Lowers a part of body.

(x) Agonistic: Opposed in action by another muscle.

(xi) Antagonistic: Counteracts the action of another muscle.

(xii) Sphincter: Closes a natural orifice or passage.

(xiii) Constrictor: Causes constriction or squeezing.

The adductor and abductor, elevator and depressor, pronator and supinator, and sphincters and dilators are all antagonistic muscles.

Important muscles

Table: 5.5-5 In man total no. of muscles: 639 muscles

Biceps and Triceps	Arm
Gastrocnemius	Shank of leg
Gluteimaximus	Buttock muscles
Oblique	Eye muscles
Rectus	Eye muscles
Maxillaries	Upper jaw
Pectoralis Major	Chest
Pectoralis Minor	Chest
Mandibularis	Muscle of lower jaw
Latissisus dorsi	Shoulder muscle
External oblique	Lower abdomen
Internal oblique	Lower abdomen
Transversus	Lower abdomen
Rectus abdominis	Lower abdomen
Stapedial muscle / arrector pilli	Smallest muscle
Sartorius femoris	Longest muscle
Gluteus maximus	Largest muscle

Movement and Locomotion

Movement is one of the most important characteristics of living organisms. Nonliving objects do not move. If nonliving objects show movement, that is always due to some external force. For example, the cart is moved by the horse and the fan revolves by the energy of electric current. The movement of a nonliving object is, therefore induced (due to external force) while the movement of living things are autonomic (self sustained). Study of movement is called kinesiology (G. Kinein = to move, Logos = study). The movement of living systems are thus autonomic or active, that is effected by the organisms themselves without external influences. On the other hand the movement of nonliving systems are induced or passive, i.e., made to occur by external forces. Movement of animals are two main types muscular and non muscular.

- (1) **Muscular movement :** Muscular movement are found in the majority of animals brought about by sliding of myofilaments. Muscular movement are further divide into two kinds Locomotion and movement of body parts.
- (i) Locomotion (locus = place + moveo = to move) : Locomotion is the movement of an animal as a whole from one place to another.

Types of locomotion: Locomotion takes several forms such as walking (man), creeping (earthworm, lizard), cursorial (Horse, flightless birds), hopping (frog, rabbit), running (dog, horse), flying (insects, birds) and swimming (fish, whale).

Animals have suitable adaptations for their specific mode of locomotion. Adaptations for running, hopping, swimming and flying are respectively called cursorial, saltatorials, natatorial, and volant adaptations. Morphogenetic movement, *i.e.*, the streaming of cells in the early embryo to form tissues or organs, may be considered a form of locomotion.

UNIVERSAL BOOK DEPOT 1960

Advantage of locomotion: Locomotion is helpful for animals as escape from predators, search of shelter, food and water, shift to favourable environment, reproduction, collect materials for nest building, locate suitable area for breeding and dispersal to new location. All forms of locomotion require energy to overcome two forces that tend to keep the animals stationary. These are friction and gravity.

- (a) **Swimming:** Water is a much denser medium than air so body modified for swimming in the form of buoyancy, fusiform body etc. Mode of swimming varies in animals. Fishes swim by moving their body and tail from side to side. Whales and dolphins swim by undulating their body and tail up and down. Insects and 4-legged vertebrates use their legs as oars to push against the water. Cuttle fish and squid are jet-propelled, taking in water and squirting it out in bursts.
- (b) Locomotion on land: For walking, running, hopping and crawling on land, animal expends energy body to prevent falling down and move forward against gravity. Powerful muscles and strong skeletal support are more important for moving on land than a streamlined body. Creeping animals have their entire body in contact with the ground. Therefore, they make a considerable effort to overcome friction.
- (c) Flying: Gravity is a major problem in flight. Wings must produce enough lift to make and keep the animal air-borne against the downward force of gravity.
- (2) Non-Muscular movement: Besides locomotion and movements of body parts, some of the cells of multicellular animals move like unicellular organisms.
- (i) Ciliary movement: The cilia present in the trachea, vasa efferentia and oviducts propel by their movements dust particles, sperms and eggs respectively. The cilia of flame cells of flatworms push excretory materials. Ciliary movements in Planaria or Dugesia also.
- (ii) Flagellar movement: The flagella of choanocytes (collar cells) of the sponges maintain a regular current of water in the body. The flagella of certain cells of gastrodermis of hydra help in the circulation of food. Sperms move by flagellar movements.
- (iii) **Pseudopodial movement :** Leucocytes and macrophages move by pseudopodial movement.
- (iv) Cytoplasmic streaming movement: Streaming movement of the cytoplasm is called cyclosis. It is observed in most of the cells.

Tips & Tricks

- Calf muscle Gastrocnemius (Shank muscle).

- Flying muscle Pectoralis major and minor.
- Strongest muscle Jaw muscle (Masseter).

- Sartorius muscle Flexion of thigh, knee and its rotation.

- Obturator externus Rotation of thigh on lateral side.
- Tensor tympani Connects the malleus to the wall of the tympanic chamber in the ear of mammal.
- Hilton muscle is aryepiglotticus muscle.
- In children the bone are more flexible and brittle because their bone have large quantity of organic substances and little salt.
- Hardest tissue in human body tooth enamel
- In muscular hypertrophy cells increase in size by synthesizing the length of a myofibril.
- Presence of furcula in birds.
- Endoplasmic reticulum or sarcoplasmic reticulum play a major role during muscle contraction, muscle excitement and muscle relaxation.
- In birds, fore limbs are modified into wings.
- Urostyle present in caudal region of frog.
- Tail vertebrae of birds form pygostyle.
- Birds has pneumatic bone.
- Six typical vertebrae present in frog.
- Central shaft of a long bone is known as diaphysis.
- Curved bone is structurally designed to absorb the stress of the body weight at several different points so that the stress is evenly distributed.
- Tibio-fibula is the shank bone.
- ✓ Joint between skull and atlas which allows nodding movement is called atlanto-occipital joint.
- Sphenoid is called as key stone bone of cranial floor, because it articulates with all other cranial bones.
- Ethmoid bone with cribriform plate with 'crista galli' triangular process. Crista galli serves as point of attachment for meninges that cover the brain.
- The bones common to face and cranium are frontal.
- Dermatocranium of skull comprises of membranous bone.
- Coronoid process is a part of lower jaw in mammalian skull.
- Sella turcica is found in base-sphenoid bone. It is a depression in skull which lodges the pituitary body.
- Amphibian & mammalia has dicondylic skull and reptiles, birds has monocondylic skull.
- Alar process is a part of hyoid apparatus.
- Hammer shaped bone in skull of frog is squamosal.
- Rigor mortis It is the state of body stiffening after death due to non separation of actin and myosin filaments caused by non-availability of ATP.
- Cori's cycle It is the passage of lactic acid produced in muscles into liver where 80% of it is changed to glucose/glycogen for continued supply to muscles. The remaining is oxidised.

Ordinary Thinking

Objective Questions

Axial skeleton

Bone marrow is largely composed of

[CBSE PMT 1990]

- (a) Periosteum and osteoblast
- (b) Adipose tissue and blood vessels
- (c) Yellow and elastic tissue
- (d) Cartilage and elastic tissue
- The collar bone is known is

[MP PMT 2012] (b) Coracoid

- (a) Scapula
- (c) Stapes
- (d) Clavicle
- The bony sockets of the jaws in which the teeth are 3. implanted, are known as
 - (a) Alveolus
- (b) Fossae
- (c) Dentaries
- (d) Thecae
- The type of vertebrae in sub-order ophidia is [Pb. PMT 1999]
 - (a) Amphicoelous
- (b) Acoelous
- (c) Heterocoelous
- (d) Procoelous
- Number of cranial nerves in mammal are [RPMT 1995; 5. KCET 2000; Odisha JEE 2008]
 - (a) 10 pairs
- (b) 8 pairs
- (c) 12 pairs
- (d) 16 pairs
- 6. Nucleus pulposus is

- [AFMC 2004]
- (a) A type of special cell found in myelin sheath of a nerve cell of vertebrate
- (b) A depression for pituitary is found in mammalian skull
- (c) A large nucleus found in Schwann cells of nerve fibre
- (d) A remain of embryonic notochord found in the central portion of inter-vertebral discs of vertebrae of mammals
- The first vertebra, the atlas by its articulation with axis 7. vertebra facilitates a
 - (a) Noding movement
- (b) Sideway movement
- (c) Rotatory movement
- (d) Backward movement
- The vertebrae in which centrum is absent and transverse 8. process are present is known as
 - (a) Lumber vertebrae
- (b) Anterior thoracic
- (c) Axis vertebrae
- (d) Atlas vertebrae
- 9. The number of vertebrae present in cervical, thoracic, lumbar, sacral and coccyx regions respectively are [NCERT; MH CET 2000; BHU 2001; Kerala PMT 2003, 06;

HP PMT 2005; Odisha JEE 2008; AFMC 2008]

- (a) 12, 7, 5, 1, 1
- (b) 1, 7, 5, 12, 1
- (c) 7, 5, 1, 12, 1
- (d) 7, 12, 5, 1, 1
- (e) 5, 12, 7, 1, 1
- Which one of the following items gives its correct total 10. [CBSE PMT 2008] number
 - (a) Types of diabetes 3
 - (b) Cervical vertebrae in humans 8
 - (c) Floating ribs in humans 4
 - (d) Amino acids found in proteins 16
- Find out the correct order of number of bones in the parts of 11. skull such as cranial bone, facial bone, hyoid bone and [Kerala PMT 2007] middle ear bone respectively
 - (a) 14, 8, 1 and 6
- (b) 6, 8, 14 and 1
- (c) 14, 8, 6 and 1
- (d) 8, 6, 14 and 1
- (e) 8, 14, 1 and 6

- The number of vertebrae in rabbit is
 - (a) 40
- (c) 44

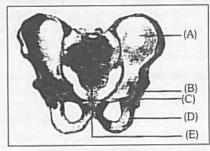

- (d) 46
- Lumbar vertebra are found in
 - (a) Neck region
- (b) Abdominal region

[CPMT 2005]

IPb. PMT 19991

[CPMT 2009]

- (c) Hip region
- (d) Thorax
- The skull of a bird is
- (b) Monocondylic
- (a) Dicondylic
- (c) Amphicondylic
- (d) None of these
- The opening at the base of the skull for the spinal cord is [CMC Vellore 1993; RPMT 1995; CPMT 2010]
 - (a) Foramen Magnum
- (b) Foramen of Monro
- (c) Obturator foramen
- (d) Foramen of Magendie
- The 8th and 9th ribs are known as false ribs because their 16. [CPMT 1992] external portions are attached to
 - (a) Xiphisternum
- (b) Costa of 7th rib
- (c) They have no costa
- (d) They are not true ribs
- Which one is not cranial bone 17.
- [GUJCET 2015]
- (a) Frontal
- (b) Zygometic (d) Sphenoid
- (c) Temporal Thoracic cage in rabbit is made up of 18.
- (a) Ribs, vertebral column and diaphragm
 - (b) Ribs, diaphragm and sternum
 - (c) Vertebral column, diaphragm and sternum
 - (d) Ribs, vertebral column & sternum
- In the pelvic girdle of man A, B, C, D and E respectively represents [Kerala PMT 2008]

- (a) A pubis, B acetabulum, C ilium, D ischium, E pubic symphysis
- (b) A ilium, B acetabulum, C pubis, D ischium, E pubic symphysis
- (c) A ischium, B acetabulum, C pubis, D ilium, E pubic symphysis
- (d) A ilium, B pubis, C acetabulum, D pubic symphysis, E - ischium
- (e) A ilium, B acetabulum, C pubic symphysis, D ischium, E - pubis
- The vertebrae in birds are mostly 20.

[CBSE PMT 2000; MH CET 2001]

- (a) Procoelous
- (b) Amphicoelous
- (c) Opisthocoelous (d) Heterocoelous Vertebral formula for human beings is [Kerala PMT 2006] 21.

 - (a) $C_5T_{12}L_7S_5C_{3-5} = 33 35$ (b) $C_7T_{12}L_5S_5C_{3-5} = 33 35$ (d) $C_7T_{10}L_5S_5C_{3-5} = 33$
 - (c) $C_5 T_{10} L_5 S_5 C_{3-5} = 33$ Centrum of man is
 - (a) Procoelus
- (b) Amphicoelus
- (c) Amphiplateus
- (d) Ophisthocoelous

160	
и.	
12	UNIVERSAL
ж.	BOOK DEPOT 1960

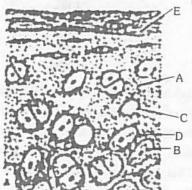

- 23. Long neck of camel is due to [BHU 1995; CPMT 1995] (a) Increase in length of cervical vertebra
 - Due to bony plate between two vertebra (b)
 - (c) Due to muscle in between two vertebra
 - (d) None of the above
- 24. Sella turcica is a
 - (a) Covering of kidney
 - (b) Covering of testis
 - Depression in brain
 - (d) Depression in skull which lodges the pituitary body
- In which bone the chondrocytes are replaced by osteocytes
 - (a) Maxilla
- (b) Nasal
- (c) Dentary (d) Vomer 26.
- Which one of the following is the correct description of a certain part of a normal human skeleton

[CBSE PMT (Mains) 2010]

- (a) Parietal bone and the temporal bone of the skull are joined by fibrous joint
- (b) First vertebra is axis which articulates with the occipital condyles
- (c) The 9^{th} and 10^{th} pairs of ribs are called the floating ribs
- (d) Glenoid cavity is a depression to which the thigh bone articulates
- 27. The number of floating ribs in human body is

[CBSE PMT 1995, 2007; AFMC 2000]

- (a) 6 pairs (c) 5 pairs
- (b) 3 pairs
- Centrum of 8th vertebra of frog is 28.
- (d) 2 pairs [DUMET 2009]
- (a) Amphiplatyon
- (b) Procoelous
- (c) Amphicoelous
- (d) Opisthocoelous
- In the first two or three lumbar vertebrae there is a small median process below the centrum, this is called
 - (a) Pre-zygapophysis
- (b) Post-zygapophysis
- (c) Hypapophysis
- (d) Neural spine
- In the diagram of section of Hyaline cartilage, the different parts have been indicated by alphabets; choose the answer in which these alphabets correctly match with the parts they indicate [KCET 2004]

- (a) A = perichondrium
 - C= Lacuna
 - E= Chondrin
- (b) A= Capsular matrix C= Lacuna
 - E= Chondrin
- (c) A= Chondrin C= Lacuna
 - E= Perichondrium
- (d) A= Chondrin C= Chondrocyte
 - D= Perichondrium

- B= Chondrocyte
- D= Capsular matrix
- B= Chondrocyte
- D= Perichondrium
- B= Chondrocyte D= Capsular matrix
- B= Lacuna
- D= Capsular matrix

- Bone related to skull is
 - (a) Atlas
- [CBSE PMT 2000] (b) Caracoid
- (c) Artenoid
- (d) Pterygoid
- 32. What is correct about human body
 - (a) There are 5 vertebra in the neck (b) Brain box is made up of 4 bones
 - There are 15 pairs of ribs
 - (d) There are 12 thoracic vertebra
- In mammals (rabbit), the zygomatic arch is formed by 33.
 - - [CPMT 1998]

[MP PMT 1993]

- (a) Maxilla, premaxilla and squamosal
- (b) Periotic, jugal and palatine
- (c) Maxilla, squamosal and jugal
- (d) Jugal, maxilla and periotic
- A vertebra has a convexity both in front and behind it. It is called [AFMC 1997; MH CET 2002; BHU 2012]
 - (a) Procoelous
- (b) Amphicoelous
- (c) Acoelous
- (d) Amphiplatyon
- The last two pairs of ribs are named floating ribs because
 - (a) Their sternal parts are attached to the sternum directly
 - (b) Their sternal parts are attached on the 7th pair of ribs
 - Their sternal parts remain free and do not even reach the sternum
 - (d) They float in the body cavity
- Special fibrous joint occuring exclusively in skull which is the tightest type of joint is [NCERT; CBSE PMT 1993]
 - (a) Suspensorium
- (b) Suspensory ligament
- (c) Suture
- (d) Occipital
- The vertebrae which bears the whole weight of the skull is 37. [CBSE PMT 1993]
 - (a) Axis
- (b) Sacral
- (c) Cervical
- (d) Atlas
- The parasphenoid bone in frog forms
 - [CPMT 2004]
 - (a) Base of cranium
 - (b) Floor of cranium
 - (c) Dorsal side of cranium
 - (d) Dorsolateral side of cranium
- 39. How many ribs are present in human beings
 - [CPMT 1994; HP PMT 2005]
 - (a) 6 pairs
- (b) 9 pairs
- (c) 12 pairs
- (d) 15 pairs
- 40. Axis vertebra of a mammal differs from atlas in
 - [CPMT 1993; MP PMT 1994]

[MP PMT 2007]

- (a) Absence of centrum
- (b) Presence of centrum
- (c) Presence of central canal
- (d) Presence of odontoid process
- 41. Number of bones in skull is
 - (a) 26
 - (c) 107

42.

43.

- (b) 28 (d) 29
- In human beings the cranium is formed by
- [AIIMS 2000; MHCET 2000; AMU (Med.) 2010] (a) Eight bones of which two are paired
- (b) Fourteen bones of which six are paired
- (c) Ten bones of which two are paired
- (d) Twelve bones of which four are paired
- Which of the following is unpaired bone
- (a) Premaxilla
- (b) Pro-otics
- (c) Sphenethmoid
 - (d) Pterygoid In man the axial skeleton is made up of
 - (a) 80 bones
- (b) 100 bones
- (c) 103 bones
- (d) 106 bones

- The number of bones in half of the lower jaw of man is
 - (a) 1

(b) 4

(c) 6

- (d) 8
- In man the thoracic basket is composed of

[MP PMT 2002, 06]

- (a) Ribs and thoracic vertebrae
- (b) Ribs and sternum
- Ribs, sternum and vertebrae
- (d) Ribs, sternum and thoracic vertebrae

Innominate is a 47.

[CPMT 2009]

- (a) Nerve
 - (b) Muscle
 - (c) Animal
- (d) A Part of skeleton and anartcry
- Tongue bone is 48.
 - (a) Hyoid bone
- (b) Maxillary
- (c) Dentary
- (d) Quadrato-jugal
- Human vertebral column consists of 33 vertebrae and 49. [CPMT 1992; BHU 2012] hones
 - (a) 33

(b) 26

(c) 27

- (d) 29
- Cervical vertebrae are located in

[HP PMT 2005]

- (a) Thoracic region
- (b) Abdominal region
- (c) Neck region
- (d) Lumbar region
- The number of cervical vertebrae in camels is 51.

[CBSE PMT 2002]

- (a) Same as that in rabbit
- (b) Same as that in frog
- (c) Less than that in giraffe (d) More than that in horse
- The major function of the intervertebral discs is to 52.

[DUMET 2010]

- (a) Absorb shock
- (b) String the vertebrae together
- (c) Prevent injuries
- (d) Prevent hyperextension
- Out of 'X' pairs of ribs in humans only 'Y' pairs are true ribs. Select the option that correctly represents values of X and Y [NEET 2017] and provides their explanation

(a)	X=12, Y=7	True ribs are attached dorsally to vertebral column and ventrally to the sternum
(b)	X=12, Y=5	True ribs are attached dorsally to vertebral column and sternum on the two ends
(c)	X=24, Y=7	True ribs are dorsally attached to vertebral column but are free on ventral side
(d)	X=24, Y=12	True ribs are dorsally attached to vertebral column but are free on ventral side

Appendicular skeleton

In rabbit radius and ulna are 1.

[MP PMT 1992]

- (a) Completely fused together
- (b) Completely separated
- (c) Fused in middle and separated at both the ends
- (d) Separated but united at both the ends

A shallow depression in the scapula which receives the head 2. of the upper arm bone is known as the

CBSE PMT 1993; AIPMT (Cancelled) 2015]

Which one of the following component is the part of pectoral [CBSE PMT 1994; MP PMT 1994; DPMT 2007] girdle

- (a) Acetabulum
- (b) Neural arch
- (c) Glenoid cavity
- (d) None of the above

[NCERT; Patella, the knee cap is the example of 3. MP PMT 1996, 2007; BVP 2001; AIIMS 2003;

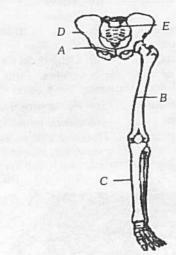

Pb. PMT 2004]

- (a) Cartilage gland
- (b) Replacing bone
- (c) Sesamoid bone
- (d) None of the above
- The protein present in the bones is known as 4.

[CBSE PMT 1992]

- (a) Chondrin
- (b) Ossein
- (c) Sclero protein
- (d) Globulin
- Humerus bone is situated in 5.
 - (a) Thigh
- (b) Lower arm
- (c) Upper arm
- (d) Shank
- Consider the diagram given below 6.

[Kerala PMT 2006]

Parts labelled as 'A', 'B', 'C', 'D', and 'E' respectively indicate

- (a) Femur, Ilium, Tibia, Pubis and Sacrum
- (b) Pubis, Tibia, Femur, Ilium and Sacrum
- (c) Ilium, Femur, Tibia, Pubis and Sacrum
- (d) Tibia, Pubis, Femur, Ilium and Sacrum
- (e) Pubis, Femur, Tibia, Ilium and Sacrum
- Symphysis contains 7.

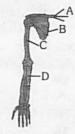

[AFMC 2012]

- (a) Hyaline cartilage
- (b) Fibrous cartilage (c) Calcified cartilage
- (d) None of these
- Outer covering of cartilage is [DPMT 1993; WB JEE 2010]
 - (a) Perichondrium
- (b) Periosteum
- (c) Endo-osteum
- (d) Peritonium

[NCERT]

9 Which option is correct for the region labelled as a, b, c and d in the given diagram [NCERT: GUJCET 2014]

- (a) A Clavicle, B Scapula, C Humerus, D Ulna
- (b) A Scapula, B Clavicle, C Humerus, D Ulna
- (c) A Clavicle, B Ulna, C Radius, D Humerus
- (d) A Clavicle, B Glenoid cavity, C Radius, D Ulna
- 10. The longest bone of the human body is

[NCERT; Kerala PMT 2009]

- (a) Humerus
- (b) Tibia
- (c) Vertebra
- (d) Femur
- (e) Incus
- 11. Olecranon fossa is present over

[MH CET 2004]

- (a) Scapula
- (b) Ulna
- (c) Radius
- (d) Humerus
- 12. Synsacrum of fowl is consist of about
- [BHU 2004]

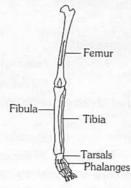

- (a) 29 vertebrae
- (b) 3 vertebrae
- (c) 16 vertebrae
- (d) Single vertebrae
- 13. The pelvic girdle of birds is attached to a complex structure formed by the fusion of last thoracic, all lumbar and first five caudal vertebra. This structure is called [MP PMT 1993]

Or

In birds, some of the vertebrae are fused to form

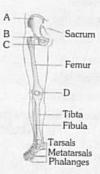

[MHCET 2001; CBSE PMT 2001]

- (a) Synsacrum
- (b) Symphysis
- (c) Synkaryon
- (d) Sympelvis
- Given below is a diagram of the left human hindlimb as 14. seen from front. It has certain mistakes in labeling. Two of the wrongly labelled bones are [AIIMS 2005]

- (a) Tibia and tarsals
- (b) Femur and fibula
- (c) Fibula and phalanges
- Tarsals and femur

Consider the following diagram. Identify A, B, C and D

- (a) A Ilium, B Pubis, C Ischium, D Patella
- (b) A Ilium, B Pubis, C Patella, D Ischium
- (c) A Ischium, B Pubis, C Ilium, D Patella
- (d) A Pubis, B Ilium, C Ischium, D Patella
- 16. Choose the correct option regarding a normal human
 - A. The skull is dicondylic
 - Metacarpals are five in numbers
 - Patella is a cup-shaped bone covering the knee dorsally
 - Scapula is a large triangular flat bone, situated on the ventral side of the thorax
 - The pelvic girdle has two coxal bones

[Kerala PMT 2012]

- (a) A and E alone are wrong (b) A and B alone are wrong
- (c) B and E alone are wrong (d) C and D alone are wrong
- (e) E alone is wrong
- 17. The pectoral and pelvic girdles and the bones of limb form

[DPMT 1993; MHCET 2000]

- (a) Axial skeleton
- (b) Appendicular skeleton
- (c) Visceral skeleton
- (d) Outer skeleton
- What will happen if a bone is kept in 10% KOH solution for 18. 3 days
 - (a) Remain unchanged
- (b) Dissolved
- (c) Become soft and elastic (d) Break
- The canal seen in the bone of mammals are [AFMC 1993]
 - (a) Haversian canals only
 - (b) Volkmann's canals only
 - (c) Haversian and Volkmann's canals
 - (d) Canal of Schlemm
- 20. Number of bones in human body is

[NCERT:

- CMC Vellore 1993; Pb. PMT 2000; JIPMER 2002]
- (a) 260 (c) 306
- (b) 206 (d) 203
- The total number of bones in your right arm is

[NCERT; AFMC 2004]

Total number of bones in the hind limb of a man is

[NCERT; CBSE PMT 1998]

(a) 30

(b) 32

(c) 35

(d) 40

- (c) Involuntary, striated
- (d) Involuntar, smooth

[MP PMT 1994]

- 22. Cori's cycle operates in
 - (a) Liver
- (b) Liver and muscles
- (c) Nerve
- (d) Muscles
- 23. Contraction of a muscle is caused by (a) Myosin
 - (b) Actin
 - (c) ATP
- (d) Actomyosin
- 24. The biceps and triceps muscles are found in
 - (a) Fore arm
- (b) Shank
- (c) Shoulder
- (d) Lower jaw
- 25. For the given statement 'X' and 'Y', which option is the correct option

Statement 'X' - Red muscle are also called aerobic muscle Statement 'Y' - Red muscle possesses large amount of mitochondria which can utilize large amount of oxygen stored in them for ATP production [GUJCET 2014]

- (a) Statement 'X' and 'Y' are correct and statement 'Y' is incorrect explanation for 'X'
- (b) Statement 'X' is correct and 'Y' is incorrect
- (c) Statement 'X' is incorrect and 'Y' is correct
- (d) Statement 'X' and 'Y' are correct and statement 'Y' is correct explanation for 'X'
- 26. Ciliary muscles are found in
 - (a) Diaphragm of a mammal
 - (b) Eyes of vertebrates
 - (c) Heart of vertebrates
 - (d) Stomach of frog
- The given figure is associated with myosin monomer 27. (meromyosin). Identify A to C [NCERT; KCET 2015]

- (a) A cross arm, B head, C ATP binding sites
- (b) A head, B cross arm, C ATP binding sites
- (c) A head, B cross arm, C Ca+2 binding sites
- (d) A head, B cross arm, C GTP binding sites

28. Electron microscopic studies of the sarcomeres have revealed that during muscle contraction

[MHCET 2003; KCET 2005; NEET (Kamataka) 2013]

- (a) The width of A-band remains constant
- (b) The width of the H-zone becomes smaller
- The width of I-band increases
- The diameter of the fibre increases
- 29. Latissius dorsi muscles are
 - (a) Muscles of fore arm
- (b) Muscles of lower jaw
- (c) Muscles of the chest
- (d) Muscles of the shoulder
- During muscle contraction 30.
- [AMU (Med.) 2005]
- (a) Chemical energy is changed into electrical energy
- (b) Chemical energy is changed into mechanical energy
- (c) Chemical energy is changed into physical energy
- (d) Mechanical energy is changed into chemical energy
- 31. The H-zone in the skeletal muscle fibre is due to

INEET 20131

- (a) Extension of myosin filaments in the central portion of the A-band
- (b) The absence of myofibrils in the central portion of A-band
- (c) The central gap between myosin filaments in the A-band
- (d) The central gap between actin filaments extending through myosin filaments in the A-band
- 32. Identify the tissue shown in the diagram and match with its characteristics and its location

[NEET (Kamataka) 2013]

- (a) Smooth muscles, show branching, found in the walls of
- (b) Cardiac muscles, unbranched muscles, found in the walls of the heart
- (c) Striated muscles, tapering at both-ends, attached with the bones of the ribs
- (d) Skeletal muscle, shows striations and closely attached with the bones of the limbs

1. Match the following and mark the correct option

Column I

- Fast muscle fibres
- B. Slow muscle fibres
- C. Actin filament
- D. Sarcomere

Options

(a) A-i, B-ii, C-iv, D-iii

- (c) A-ii, B-i, C-iv, D-iii
- Column II
- Myoglobin i.
- Lactic acid ii.
- iii. Contractile unit
- iv. I-band
 - INCERTI
- (b) A-ii, B-i, C-iii, D-iv
- (d) A-iii, B-ii, C-iv, D-i

- 2. Ribs are attached to
 - (a) Scapula (b) Sternum
 - (c) Clavicle
- (d) Ilium
- ATPase of the muscle is located in 3.

 - (a) Actinin
- (b) Troponin
- (b) Myosin
- (d) Actin
- 4. Intervertebral disc is found in the vertebral column of
 - [NCERT]

[NCERT]

[NCERT]

- (b) Reptiles
- (c) Mammals
- (d) Amphibians
- 5. Which one of the following is showing the correct sequential order of vertebrae in the vertebral column of human beings

[NCERT]

[NCERT]

- (a) Cervical lumbar thoracic sacral coccygeal
- (b) Cervical thoracic sacral lumbar coccygeal
- (c) Cervical sacral thoracic lumbar coccygeal
- (d) Cervical thoracic lumbar sacral coccygeal
- Which one of the following options is incorrect INCERTI
 - (a) Hinge joint between Humerus and Pectoral girdle
 - (b) Pivot joint between atlas, axis and occipital condyle
 - (c) Gliding joint between the carpals
 - (d) Saddle joint between carpel and metacarpals of thumb
- 7. Match the followings and mark the correct option

Column I

Column II

- A. Sternum
- Synovial fluid
- Glenoid Cavity
- Vertebrae ii.
- D. Cartilagenous joint

Freely movable joint

iv. Flat bones

iii. Pectoral girdle

- Ontions
- (a) A-ii, B-i, C-iii, D-iv
- (b) A-iv, B-iii, C-i, D-ii
- (c) A-ii, B-i, C-iv, D-iii
- (d) A-iv, B-i, C-ii, D-iii
- Macrophages and leucocytes exhibit
- [NCERT]
 - (a) Ciliary movement
- (b) Flagellar movement
- (c) Amoeboid movement
- (d) Gliding movement
- Which one of the following is not a disorder of bone[NCERT]
 - (a) Arthritis
- (b) Osteoporosis
- (c) Rickets
- (d) Atherosclerosis
- Which one of the following statement is incorrect [NCERT]
 - (a) Heart muscles are striated and involuntary
 - (b) The muscles of hands and legs are striated and voluntary
 - The muscles located in the inner walls of alimentary canal are striated and involuntary
 - (d) Muscles located in the reproductive tracts are unstriated and involuntary
- Which one of the following statements is true
 - [NCERT] (a) Head of humerus bone articulates with acetabulum of pectoral girdle
 - (b) Head of humerus bone articulates with glenoid cavity of pectoral girdle
 - (c) Head of humerus bone articulates with a cavity called acetabulum of pelvic girdle
 - (d) Head of humerus bone articulates with a glenoid cavity of pelvic girdle

UNIVERSAL BOOK DEPOT 1960

Critical Thinking

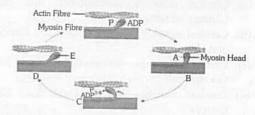

Objective Questions

- Typically all mammals have seven cervical vertebrae except in [CBSE PMT 1990]
 - (a) Elephant
- (b) Man
- (c) Kangaroo
- (d) Sea cow
- 2. The membranous areas between the cranial bones of the foetal skull are called [DUMET 2010]
 - (a) Areolas
- (b) Foramina
- (c) Sutures
- (d) Fontanelle
- Select the correct statement regarding the specific disorder of muscular or skeletal system[NCERT; CBSE PMT (Pre.) 2012]
 - (a) Muscular dystrophy-age related shortening of muscles
 - (b) Osteoporosis-decrease in bone mass and higher chances of fractures with advancing age
 - (c) Myasthenia gravis—auto immune disorder which inhibits sliding of myosin filaments
 - (d) Gout-inflammation of joints due to extra deposition of calcium
- Which of the following is not a function of the skeletal system [AIPMT 2015]
 - (a) Storage of minerals
- (b) Production of body heat
- (c) Locomotion
- (d) Production of erythrocytes
- 5. The zygomatic process in mammals arises from
 - (a) Premaxilla
- (b) Maxilla
- (c) Mandible
- (d) Squamosal
- In frog, the vertebra with an anterior convex surface is
 - [AIIMS 2000; CPMT 2001]
 - (a) Atlas
- (b) Urostyle
- (c) 8th vertebra
- (d) 9th vertebra
- Epiphyseal discs, which are present at the ends of long bones are responsible for [AIIMS 1993]
 - (a) Bone elongation
 - (b) Growth of thickness of the bone
 - (c) Remodelling the shape of bone
 - (d) Formation of Haversian canal
- 8. A greater trochanter is found in [BHU 2002]
 - (a) Femur
- (b) Humerus
- (c) Ulna
- (d) Radius
- 9. The Paget's disease is caused by [AMU (Med.) 2009]
 - (a) Prolonged deficiency of vitamin D in adults
 - (b) Abnormal bone resorption by abnormal osteoclasts
 - (c) Excess alkaline phosphatase
 - (d) Excess production and abnormal organization of collagen
- Bone is distinguished from the cartilage by the presence of [JIPMER 1993; CPMT 1993, 2002]
 - (a) Collagen
- (b) Blood vessels
- (c) Lymph vessels
- (d) Haversian canals
- 11. Which of the following is not found in birds [AIIMS 1999]
 - (a) Pectoral girdle
- (b) Pelvic girdle
- (c) Hind limb
- (d) Fore limb
- 12. Interphalangeal joints are also called as
 - (a) Fixed joints
- (b) Hinge joints
- (c) Movable joints
- (d) Straight joints

- The immediate regeneration of ATP used up during muscle contraction is facilitated by [AIIMS 1992]
 - (a) Glucose
- (b) Glycogen
- (c) Lactic acid
- (d) Creatine phosphate
- Smallest muscle in the human body
 - [JIPMER 2002]

- (a) Sartorius
- (b) Spinal muscle
- (c) Stapes
- (d) Stapedius
- 15. Quadriceps and Gastrocnemius muscle lies in
 - [MP PMT 2001]

- (a) Hands
- (b) Legs
- (c) Shoulder
- (d) Wrist
- 16. See the following figure describing muscle contraction

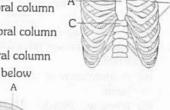

Identify A, B, C, D and E

[NCERT]

B

- (a) A Cross bridge, B Cross bridge formation, C Sliding/rotation, D ADP, E Breaking of cross bridge
- (b) A Cross bridge, B Breaking of cross bridge, C -Sliding/ rotation, D - Cross bridge formation, E - AMP
- (c) A Cross bridge, B Cross bridge formation, C -Sliding/ rotation, D - Breaking of cross bridge, E - ATP
- (d) A Cross bridge, B Cross bridge formation, C -Breaking of cross bridge, D - Sliding (rotation), E - ATP
- The given figure represents rib cage. Identify A, B and C respectively

 [NCERT]
 - (a) Tarsal, ribs, vertebral column
 - (b) Scapula, ribs, vertebral column
 - (c) Sternum, ribs, vertebral column
 - (d) Coccyx, ribs, vertebral column
- 18. Study the diagram given below

B
Sphenold bone
Ethmoid bone
Lacrimal bone
Nasal bone
Zygomatic bone
Maxilla
Mandible
E

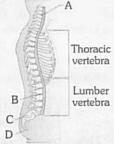

Parts labelled as A, B, C, D and E respectively represent

[NCERT]

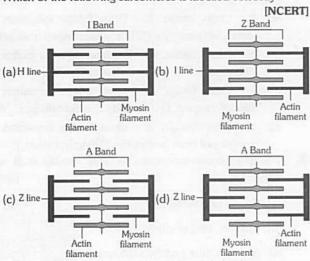

- (a) Parietal bone, Frontal bone, Temporal bone, Occipital condyle and Hyoid bone
- (b) Frontal bone, Parietal bone, Temporal bone, Hyoid bone and Occipital condyle
- (c) Frontal bone, Temporal bone, Parietal bone, Occipital condyle and Hyoid bone
- (d) Frontal bone, Parietal bone, Temporal bone, Occipital condyle and Hyoid bone

The given figure indicates vertebral column of human (right lateral view). Parts labelled as A, B, C and D respectively [NCERT] represent

- (a) Cervical vertebra, Intervertebral disc, Sacrum and Lumbar vertebra
- (b) Cervical vertebra, Intervertebral disc , Lumbar vertebra and Coccyx
- (c) Cervical vertebra, Intervertebral disc, Sacrum and Coccyx
- (d) Lumbar vertebra, Intervertebral disc, Sacrum and Coccyx
- Which of the following sarcomeres is labelled correctly 20.

- Osteoporosis, an age related disease of skeletal system, may 21. [NEET (Phase-II) 2016] occur due to
 - (a) Accumulation of uric acid leading to inflammation of ioints
 - (b) Immune disorder affecting neuromuscular junction leading to fatigue
 - (c) High concentration of Ca++ and Na+
 - (d) Decreased level of estrogen

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- If both the assertion and the reason are true and the reason (a) is a correct explanation of the assertion
- If both the assertion and reason are true but the reason is (b) not a correct explanation of the assertion
- If the assertion is true but the reason is false (c)
- (d) If both the assertion and reason are false
- If the assertion is false but reason is true (e)

- Ball and socket joints are the most mobile Assertion joints.
 - Synovial fluid is present here. Reason
- 2. Assertion Locomotion in Hydra is carried out by two types of contractile cells.
 - Reason Muscle fibres are lacking in Hydra.
- 3. Assertion Triceps is said to be an extensor muscle for elbow joint.
 - Triceps relaxes durings extension of Reason

forearm at the elbow joint.

Muscle contraction force increases with rise Assertion

in strength of stimulus.

Reason This is due to increased contraction of

individual muscle fibres with increase in

stimulus strength.

S Answers and Solutions

Axial skeleton

- (d) In the procoelous vertebrae, the anterior surface is concave and posterior surface convex.
- 14. (b) Since it has a single occipital condyle.
- 15. (a) The cranial cavity in which the brain is lodged posteriorly opens by foramen magnum. The brain is connected to spinal cord at this foramen.
- 16. (b) The eighth, ninth and tenth pairs of ribs are called false ribs. They articulate by cartilage with costal cartilage of the seventh rib.
- 20. (d) Vertebrae of birds are mostly heterocoelous.
- 21. (b) Cervical vertebrae are 7 in number, thoracic 12 in number, lumbar 5 in number, sacral 5 in number in childhood, they fuse in adults to form a single bone, the sacrum coccygeal vary from 3–5 in number.
- (b) Long neck of camel is due to bony plates between two vertebra (which are long).
- 24. (d) Sella turcica or 'Turkish saddle' is a depression in the floor of the mammalian skull in the sphenoid (Basi sphenoid) bone in which the pituitary body is lodged.
- **26.** (a) Immovable/fixed/fibrous joint are present between the skull bones. So, between parietal bone and the temporal bone of the skull are joined by fibrous joint.

- 27. (d) The last two pairs (11th and 12th) of ribs which have no connection with the sternum at all are known as floating ribs.
- 29. (c) The first two or three lumbar vertebrae has another unpaired additional process, the hypapophysis, which extends downwards from the midventral part of centrum.
- **31.** (d) Pterygoid is short rod shaped bone forming the posterior roof of mouth cavity.
- (d) Thoracic vertebrae are 12 in number, present in the chest.
- 34. (c) Acoelous means without cavity on either of its ends. It can be amphiplatyon with both ends flats or amphidicondylar with both ends convex. Procoelous have anterior concavity, amphicoelous has both sides concave.
- 36. (c) The skull bones fit together by sutures.
- 37. (d) According to Greek mythology, their one God Atlas supports the earth. If the skull can be considerd as the globe (earth), then first vertebra which bears whole of its weight can be regarded as Atlas. It is named on this basis only.
- 38. (b) Parasphenoid bone is a flattened and inverted T-shaped bone which lies in the median along the floor of cranium.
- 39. (c) 12 pair ribs are present in human beings, 1st to 7th pairs are called true ribs, 8th, 9th, 10th pairs are called false ribs, and last two pairs of ribs are called floating ribs.
- 41. (b) Number of bones in skull is 28
 Bones of Cranium = 8
 Facial bones = 14
 Earossicles = $\frac{6}{28}$
- **42.** (a) The cranium is formed by 8 bones. (1 frontal bone, 2 parietal, 2 temporal, 1 occipital, 1 sphenoid, 1 ethmoid).
- 43. (c) The cranial segment is also cartilaginous in tadpole larva, but later, most of it changes into a tubular bone called sphenethmoid.
- (a) It forms the main axis. It consists of skull 22 bones, vertebral column 33 vertebrae, sternum 1 and ribs 24
- 46. (d) The dorsal, ventral and lateral part of thoracic basket are respectively formed of thoracic vertebrae, sternum, and ribs.
- 47. (d) Half of the vertebrate pelvic girdle consists of three bones ilium, ischium and pubis which fuse together in adult to be called innominate bone (hip bone).
- **48.** (a) Hyoid bone is attached with the some muscles of the tongue and floor of the mouth.
- 50. (c) Cervical vertebrae are located in neck region.
- 53. (a) Human has 12 pairs of ribs, out of which first 7 pairs are called true or vertebrosternal ribs, next 3 pair are called false or vertebrochondral ribs and last 2 pairs are called floating or vertebral ribs.

Appendicular skeleton

- 1. (d) In rabbit, radius and ulna are separate bones but they are joined at both ends by ligaments.
- 2. (c) Glenoid cavity articulates humerus with scapula.
- (c) Patella is the small bone in knee joint between femur and tibia. It is a sesamoid bone developed in the tendon of quadriceps femoris muscle.

- (b) The protein present in the bone is known as ossein. Which activate the bone formation.
- 5. (c) Each upper arm or brachium of mammals also has a single long humerus bone whose swollen, spherical, and smooth proximal end or "head" fits into a glenoid cavity of the pectoral girdle on its side.
- (a) All mature cartilages are surrounded by a firmly attached, dense fibrous sheath of connective tissue, called perichondrium.
- (a) The labelled parts are a Clavicle, b Scapula, c Humerus and d – Ulna* (Wrongly given as Radius).
- 11. (d) Humerus is the bone of upper arm. It articulates with ulna of fore arm. Two depression just above trochlea on anterior aspect are coronoid fossa and radial fossa respectively receives coronoid process of ulna and head of radius. One large depression on the posterior aspect is olecranon fossa receives olecranon process of ulna in extention of elbow.
- 12. (c) Synsacrum is the thoracic region of vertebral column in fowl. It consist of about 16 fused vertebrae and provide support to ilia bones of immense pelvic girdle.
- **13.** (a) Synsacrum is a composite bone in birds which consists of about 16 fused vertebrae of different regions.
- 17. (b) Appendicular skeleton is situated at the lateral sides which actually extend outwards from the principal axis. It consists of pectoral and pelvic girdle and bones of arms and legs.
- 18. (a) A bone kept in KOH remain unaffected, only the surrounding muscles and connective tissue get dissolved, so that the bone now appears clean.
- (b) Human skeleton is mainly formed of bones and cartilages. It is formed of 206 bones in adult man.
- 21. (a) Each hind limb contains 30 bones namely femur in thigh, patella in the knee, tibia and fibula in the lower leg, 7 tarsals in the ankle, 5 meta-tarsals in the sole and 14 phalanges in toes.
- **25.** (a) Within the matrix of the compact bone of the shaft of long mammalian bones. (like humerus, femur, tibia), a network of branching canals (called haversian canals) is present in which lie the blood vessels.
- 27. (a) Ends of long bones are covered with cartilage. Ends of long bones takes part in forming the joint so the ends are covered by hyaline cartilage (articular cartilage).
- 28. (a) Ulna is produced into an olecranon process, to articulate into olecranon fossa and trochlea of humerus by a hinge joint.
- **29.** (a) Each leg of cockroach is consist of five segments i.e., basal flat coxa, a small trochanter a long femur, a slender spiny tibia, and the foot tarsus.
- **31.** (b) Astragalus and calcaneum are the bones of hind limb.
- 32. (d) Humerus is differentiated into three parts head, shaft and lower end. Shaft has a V-shaped deltoid ridge, at its middle
- 33. (a) Pelvic girdle comprises of the usual three bones ilium, ischium and pubis which are fused together into a single innominate or hip bone
- 35. (d) The ulna is thicker and longer, which bears a subterminal cup like receptacle called sigmoid notch or olecranon notch, for articulation with the distal end of humerus.
- **36.** (c) The clavicle and interclavicle form a *V*-shaped furcula or wish bone or merrythought in birds.

- **38.** (a) Ankle, also called tarsus, has 6 bones, called tarsals, arrangend in three rows having gliding joints, proximal row is with two bones. Outer calcaneum (heel bone) and inner talus.
- (d) The ventral part of each half of pectoral girdle is comprise three skeletal pieces scapula, supra scapula, and coracoid.
- 41. (b) Hip bone is formed by the fusion of three bones; ilium on upper side, pubis on inner side and ischium below the pubis.
- **42.** (c) Haversian canals are present in long bones such as humerus, femur, tibia etc.
- **43.** (c) 1 humerus, 1 radius, 1 ulna, 8 carpal bones, 5 metacarpal bones, 5 digits (14 phalanges) phalangeal formula 2.3,3,3,3.
- 44. (c) Ulna projects beyond the radius as an olecranon process which has a deep sub terminal sigmoid notch for articulation with the distal end of humerus.

Joints

- (a) An example of gliding joint is zygapophysis of adjacent vertebrae.
- 2. (c) Movable joints are called synovial joints. Which is found between humerus and ulna.
- 5. (c) The elbow joint.
- (d) Shoulder and hip joints are the examples of ball and socket joints.
- 10 (b) Hyaline cartilage forms the articular surfaces at the joints of long bones where it is called as Articular cartilage.
- 14. (b) A gliding joint is the simplest of the synovial joints. Gliding joints are found between the carpal bones and between the tarsal bones.
- **17.** (b) Hip joint (a type of ball and socket joint) found between head of femur and acetabulum of pelvic girdle.
- **18.** (d) Achilles tendon is the strongest and thickest tendon in the body. Former is a large tendon at lower end of the gastrocnemius muscle, inserted into oscalcis.
- 20. (a) Ligments connects the two bones together and acts as a shock absorber to cushion when tibia and femur came together.
- **21.** (c) Ligaments are the tissues which join the ends of bones together.
- 24. (b) Articular ends of both bones are either flat or slightly curved. To allow gliding or sliding movements as between zygopophysis of vertebrae.
- **25.** (c) Tendon is a tough non-elastic connective tissue that joins a muscle to a bone. It is consists of collagen fibres.

Muscles

- (c) Sarcolemma is present on the outside of skeletal muscle fibre. In the region of attachment, the sarcolemma is folded to form finger like projections.
- (a) Fascia, actually is a sheet of connective tissue which covers the muscle.
- 8. (c) It is the principal calf muscle in the leg of a tetrapod. It arises by two heads connected to condyles of the femur. At its lower end it has a strong tendon which joins with that of the soleus muscle to form the tendon Achilles. Its main action is to provide the propelling force for walking and running.

- 9. (a) Myosin protein forms anisotropic band and its centres forms 'M' line i.e. muscle fibre itself consists of myosin filaments. The cross bridges present in myosin molecules are enzymatic in nature and always tends towards, the centre of myosin filament thus causes the contraction of muscle fibre.
- 14. (c) During muscle fatigue due to deposition of lactic acid, cytoplasm becomes acidic thereby enzyme activity stops and food is not oxidised and as the energy is not available, muscular contraction stops.
- 16. (a) A-band has its middle a light zone called H-zone.
- (d) There are about 639 types of muscles in human body which form about half of body weight.
- 18. (b) Myosin filaments are thicker and confined to the A-bands only. They are composed of myosin protein.
- **22.** (b) In Cori's cycle large glycogen is broken down to lactic acid by glycolysis and energy is liberated. Some energy is used for regeneration of creatine phosphate and also for conversion of $4/5^{th}$ of lactic acid back to glycogen. The remaining $1/5^{th}$ of lactic acid is broken to CO_2 and H_2O .
- (d) During muscle contraction, myosin and actin form cross bridges. This complex is known as actomyosin complex.
- 24. (a) Biceps is flexor muscle, it is attached with humerus and radius bone through tendon. Biceps bends or flexes arm at elbow.
- 25. (d) Red muscles have large number of mitochondria which can utilize more stored oxygen thereby producing more ATP so are termed as aerobic muscles.
- 26. (b) They help in accomodation of lens.
- 29. (d) It helps in adduction, extension and medial rotation of the shoulder as in swimming, rowing, climbing, pulling, folding the arm behind back and scratching the opposite scapula. It also helps in violent expiratory efforts as coughing, sneezing, etc.

Critical Thinking Questions

- (d) In aquatic mammals (sirenia) cervical vertebrae are fused into a solid bony mass because of reduced neck in the manatees (sea caw) there are six cervical vertebrae only and the neural arches are sometimes incomplete.
- (d) Squamosal is the posteriormost bone of the ramus. A zygomatic process extends forwards from its outer part.
- (a) Epiphyseal plate (hyaline cartilage) is formed between diaphysis and epiphysis. This contributes in bone elongation.
- 8. (a) The greater trochanter and lesser trochanter are projections that serve as points of attachment for the tendons of some of the thigh and buttock muscles.
- 10. (d) Haversian canals are the characteristic features of bone.

- 11. (d) In birds, the fore limbs are modified to form wings.
- 12. (b) Hinge joints are found in the knee, elbow, ankle and interphalangeal joints. Thus interphalangeal joints are also called hinge joints.
- (d) The excess ATP is used to synthesize creatine phosphate, an energy rich molecule that is found in muscle fibres.
- 14. (d) The stapedius muscle, which is innervated by the facial nerve (cranial nerve VII), is the smallest of all skeletal muscles.

Assertion and Reason

- 1. (b) Synovial fluid is a thick sticky fluid of egg white consistency, secreted by synovial membranes into the synovial cavity. Though the presence of synovial fluid is one of the reasons behind the mobility of the joints, but the most accurate reason is the arrangement of the bones at the joint, the spheroidal ball-like end of one bone articulates here with the cup-shaped depression in another. This allows the bone with the ball head to be moved freely in many planes. Shoulder joints and hip joints are the ball-and-socket joints.
- 2. (a) As muscle fibres are lacking in Hydra, the animal uses two types of contractile cells for this purpose. Processes of these cells run in the body wall both along the long axis of the body and arround the central body cavity. Contraction and relaxation of these cells respectively, shorten and elongate these processes. They consequently cause all types of movement of Hydra including shortening, elongation and also bending of body and tentacular movement. Locomotion is carried out by somersaults looping.
- 3. (c) Movements are produced at joints by contraction of skeletal muscles inserted into articulating bones. The contraction of an extensor muscle extends a joint, hence causing extension of the limb. Contraction of triceps brings about the extension of forearm at the elbow joint hence it is said to be the extensor muscle for elbow joint.
- 4. (c) The muscle fibre always contracts with the maximum force and this force doesn't rise on increasing the strength of the stimulus. If the stimulus is of strength below the threshold, then the muscle fibre doesn't contract at all. This is known as All or None law. But the entire muscle doesn't obey this law, it means that force of contraction of muscle increase with rise in strength of the stimulus. This is due to the fact that the strength of the threshold stimulus varies from muscle fibre to muscle fibre in a muscle.

(a) Tendon is very dense, strong fibrous connective tissue made of collagen fibres, which connects a skeletal muscle to a bone.

5.6

Neural Control and Coordination

In all the multicellular animals above the level of sponges, the system meant to perceive stimuli detected by the receptors, to transmit these to various body parts, and to effect responses through effectors, is called *nervous system*. In vertebrates, it is highly specialized and plays at least three vital roles

- Sensory function: It senses certain changes (stimuli) both within body (internal environment) and out side body (external environment).
- (2) **Integrative functions**: It analyses the sensory information, store some aspects, and make decisions regarding appropriate behaviour.
- (3) **Motor functions**: It may respond to stimuli by initiating muscular contractions or glandular secretions.

Nervous systems in various animals

- (1) Coelenterata: True nerve cell or ganglion cells occur for the first time in coelenterates. They are derived from interstitial cells of epidermis, forming nerve net or nerve plexus below whole epidermis. A polar neurons are found in coelenterata.
- (2) Platyhelminthes: Nervous system of planarians marks the beginning of a centralized nervous system encountered in higher animals. That is made up of brain or cerebral ganglia, two lateral longitudinal nerve chords, numerous peripheral nerves and transverse commissures or connectives. This is sometimes called the ladder type of nervous system.

In Nematoda (e.g. ascaris) these system made up of central nervous system, peripheral nervous system and rectal nervous system. Rectal nervous system more developed in male. Ascaris with dorsal, ventral, and lateral nerve cords.

(3) Annelida: Nervous system well developed and concentrated. It consists of three parts: central nervous system, peripheral nervous system and sympathetic nervous system, central N.S. made up of Nerve ring and ventral nerve cord. Nerves are of mixed type, consisting of both afferent (sensory) and efferent (motor) fibres.

- (4) Arthropoda: The nervous system of prawn or arthropodo is of the annelidan type. However it is somewhat larger and has more fusion of ganglia. It consists of (i) The central nervous system including brain connected with a ventral ganglionated nerve cord through a pair of circum-oesophage al commissures, (ii) The peripheral nervous system including nerves and (iii) The sympathetic nervous system. In arthropods like cockroach sympathetic nervous system also known as stomatogastric nervous system, made up of 4 ganglion and retro-cerebral complex.
- (5) Mollusca: In gastropodes (e.g. pila) consists of paired ganglia, commissures and connective uniting them and nerves running from these central organis to all parts of the body. It has various type of ganglia as cerebral, buccal, pleuro-pedal, supra intestinal and visceral etc. In palecypoda nervous system is greatly reduced due to sluggish and sedentary mode of life and there is little evidence of the brain. But in cephalopoda shows a high grade of organization attained only by some insects and arachnids among the other invertebrates.'
- (6) Echinodermata: Echinodermates has simple and primitive type of nervous system. It has the form of a nerve net, consisting of nerve fibres and a few ganglion cells, all confined to the body wall except the visceral nerve plexus situated in the gut wall. At certain places the nervous tissue is concentrated to form distinct nerve cords. It is made up of (i) Superficial or ectoneural nervous system (ii) Hyponeural or deep nervous system (iii) Aboral or coelomic nervous system and (iv) Visceral nervous system.
- (7) Hemichordata: Nervous system is of primitive type resembling that of coelenterates and echinodermates, with both dorsal and ventral nerve cord.
- (8) Chordates: Nervous system well developed and formed by ectoderm. It is formed by central nervous system, peripheral nervous system and autonomic nervous system.

Development of central nervous system in

Nervous system begins developing early in third week of development from ectoderm. Nervous tissue also develop from ectoderm except microglial cell, develop from mesoderm. The central nervous system of vertebrates includes the brain and the spinal cord. These are derived from a longitudinal mid-dorsal ectodermal thickening of the embryo, called the medullary or neural plate. This neural plate or neural groove is converted by fusion into a closed mid-dorsal longitudinal neural tube lying above the notochord. Histologically, the embryonic neural tube exhibits three zones of cells.

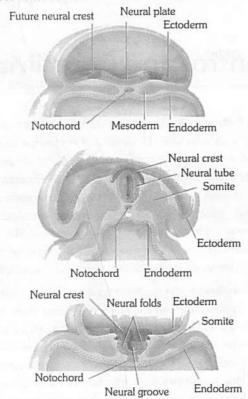

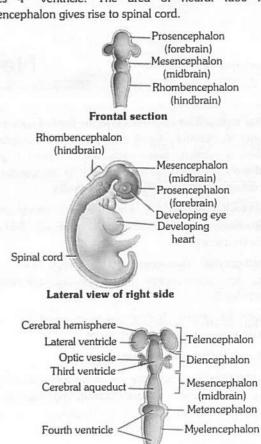

Fig : 5.6-1 Stages in the embryonic development of central nervous system

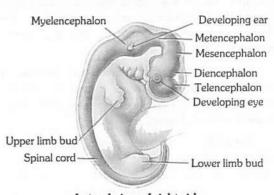

- (1) Germinal layer: These are actively dividing cells lining the neural canal. They form the connective tissue lining of neural canal, called ependyma, and ventricles of brain.
- (2) Mantle layer: It consists of embryonic neurons or nematoblasts, forming the grey matter.
- (3) Marginal layer: It consists of nerve fibres, mostly surrounded by fatty myelin sheaths, and forms the white matter. Neurons and fibres are supported by a special connective tissue of ectodermal origin, the neuroglia, cells of which become increasingly abundant and diversified in higher vertebrates.

Development of brain

The anterior end of embryonic neural tube is already enlarged forming the embryonic brain, called *encephalon*. By differential growth and two constrictions, it is divided into a linear series of three *primary cerebral vesicles*, termed the *forebrain*, *midbrain* and *hindbrain*. These give rise to the three major divisions of the adult

brain – (1) prosencephalon (forebrain), (2) mesencephalon (midbrain), and (3) rhombencephalon (hindbrain). These further become subdivided into 5 subdivisions. Prosencephalon divides into an anterior telencephalon and posterior diencephalon; the mesencephalon remain unchanged. The rhombencephalon divides into an anterior metencephalon and a posterior myelencephalon. Ultimately, telencephalon develops into cerebral hemisphere and basal ganglia and houses lateral ventricle. Diencephalon develops into thalamus, hypothalamus, and pineal gland and houses the third ventricle. Mesencephalon develops into mid brain and houses cerebral aqueduct. Metencephalon develops into pons and cerebellum; and myelencephalon develops into medulla oblongata, houses 4th ventricle. The area of neural tube inferior to myelencephalon gives rise to spinal cord.

Fig: 5.6-2 Development of the brain and spinal cord

Parts of nervous system

Central nervous system (CNS)

In all the vertebrates including man, CNS is dorsal, hollow and non-ganglionated while in invertebrates when present, it is ventral, solid, double and ganglionated. CNS is formed of two parts:

- (1) Brain Upper and broader part lying in the head.
- (2) Spinal cord Lower, long and narrow part running from beginning of neck to trunk. CNS is covered by 3 meninges and its wall has two type of matter.

Types of matter: CNS of vertebrates is formed of two types of matter –

- (i) Grey matter: It is formed of cell-bodies, non-medullated nerve fibres, neuroglia, dendrites of association neurons and motor neurons.
- (ii) White matter: It is formed of medullated nerve fibres or myelinated axon of motor and sensory neurons, which appear white due to the presence of medullary sheath.

Meninges: The meninges are connective tissue membranes which surround the brain and spinal cord of CNS. In the fishes, there is only one meninx called meninx primitiva (piamater). In amphibians, reptiles and birds, the brain is covered by two meninges or membranes: inner pia-arachnoid and outer duramater. In mammals, CNS is covered by three meninges or membranes or cranial meninges. Brain meninges are continuous with spinal meninges

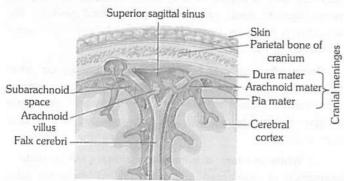

Fig: 5.6-3 Meninges of brain

The three layers of cranial meninges in order from superficial to deeper duramater, arachnoid and piamater. Duramater is nonvascular, tough made up of fibrous connective tissue. Arachnoid mater made up of reticular connective tissue with collagen and elastin fibre, while innermost vascular piamater (nutritive) made up of loose areolar connective tissue. Between dura and arachnoid mater presence of sub dural space (no CSF in mammals here), between Arachnoid and piamater presence of sub-arachnoid space (with CSF in mammals, CSF also found in ventricles and central canal). Between duramater and periosteum presence of epidural space. An extension of duramater between two cerebral hemispheres is called falx cerebri. Tentorium, an extension of duramater between cerebrum and cerebellum.

Cerebrospinal fluid: All the ventricles of the brain, central canal of spinal cord are continuous and lined by a columnar, ciliated epithelium, the ependyma. They contain lymph-like extracellular fluid called the cerebrospinal fluid (C.S.F.). This fluid is secreted by the choroid plexuses by filtration of blood. The choroid plexuses consist of loose connective tissue of pia mater covered internally by a simple cuboidal epithelium of secretory (glandular) nature. The cerebrospinal fluid slowly flows toward the fourth ventricle by secretion pressure and passes into the spinal cord. Some fluid escapes into the subarachnoid spaces through three pores a median aperture (of magendie) and a paired lateral aperture (of Luschka) in the roof of the fourth ventricle in the medulla. From the subarachnoid spaces, the cerebrospinal fluid is transferred to the blood of the venous sinuses. Nervous tissue is without lymphatic vessels.

The cerebro-spinal fluid (CSF) provides -

- (i) Protection to brain from mechanical shocks, physical injury.
- (ii) Optimum physiological fluid environment for neural functions e.g. conduction of nerve impulses, transport of aminoacids, sugars, O_2 etc.
- (iii) 'Relief' mechanism for the increase in intracranial pressure that occurs with each arterial pulse of blood to brain.
 - (iv) 'Sink' like facility for metabolites of brain.
- (v) The blood CSF barrier for selective transport process between blood and CSF.
 - (vi) Nourishment to CNS.

Major site of CSF formation is choroid plexus, and mid ventricular wall and sub-arachnoid wall also contribute. CSF is cell free, slightly alkaline, and is isotonic to plasma. Rate of formation of C.S.F is 20 ml/h (480 ml/day) approx, 1/2 litre per day. Total amount present in and around CNS is 80-150 ml it means there is atleast 3 times renewal of C.S.F. every day. CSF contains glucose, proteins, lactic acid, urea, Na⁺, K⁺, Ca²⁺, Mg²⁺, Cl⁻, HCO₃⁻ and some WBC.

Blood brain barrier facilitate maintenance of stable internal environment. It acts as physiological and pathological barrier.

☐ **Hydrocephalus**: The enlargement of head, a pathological condition characterized by an abnormal accumulation of cerebrospinal fluid resulting in headache, vomiting, pain and stiffness of the neck.

- ☐ Increased cerebrospinal fluid may result in Meningitis.
- Meningitis may occur due to infection and inflamation of meninges or injury of meninges.
- ☐ Infection may be viral, bacterial or both. The most common cause of meningitis is the infection of *Streptococcus* pneumoniae, *Neisseria meningitidis* and *Haemophilus influenzae*.
- ☐ Lumbar puncture is done for drainage of excess of cerebrospinal fluid during meningitis.
- ☐ Cerebro-spinal fluid is formed by choroid plexus (ACP and PCP).

There are three choroid plexus in humans -

- (i) Lateral choroid plexus: It is in the roof of I and II ventricle.
- (ii) Anterior choroid plexus: It is in the roof of III ventricle (diocoel).
- (iii) Posterior choroid plexus or pelochoroida: It is in the roof of IV ventricle.

Oxygen and glucose requirements: Brain controls the functions of our body organs and also provides the qualities of mind – learning, reasoning, and memory. For these activities, brain needs a large and constant energy supply. At any given time, the activities of the brain account for 20% of the body's consumption of oxygen and 15% of its consumption of blood glucose. Brain deprived of oxygen for just 5 minutes is permanently damaged. Mental confusion results if brain is deprived of glucose.

Structure of human brain (Encephalon)

It is soft, whitish, large sized and slightly flattened structure present inside cranial cavity of cranium of the skull. In man, it is about 1200-1400 gm in weight and has about 10,000 million neurons. Brain is made up of 3 parts:

(1) Fore brain or Prosencephalon: It forms anterior two-third of brain and is formed of three parts.

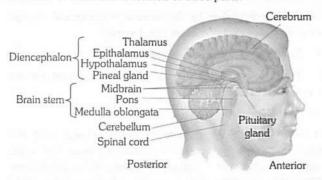

Fig: 5.6-4 Main parts of human brain visible from lateral view

Olfactory lobes : These are one pair, small sized, clubshaped, solid, completely covered by cerebral hemisphere dorsally. Each is differentiated into two parts –

- (i) Olfactory bulb: Anterior, swollen part, and
- (ii) Olfactory tract: Posterior and narrow part which ends in olfactory area of temporal lobe of cerebral hemisphere.

Function: These control the smell.

- (a) It is normal in frog, rabbit and man.
- (b) It is well developed in dog. So power of smell is more in dog.

(c) These are also well developed in dog fish and name dog fish is on the basis of well developed olfactory lobes.

Cerebrum: Cerebrum is divided into 5 lobes (a) frontal (b) parietal, (c) occipital, (d) temporal and (e) Insula. A lobe called insula is hidden as it lies deep in the sylvian fissure. The cerebral hemisphere are separated from olfactory lobes by rhinal fissure. The median fissure divides the cerebrum into a right and a left cerebral hemisphere.

A few sulci are well developed and form three deep and wide fissures which divide each cerebral hemisphere into four lobes: anterior frontal lobe, middle parietal lobe, posterior occipital lobe and lateral temporal lobe e.g. Fissure sulcus lying between the frontal and parietal lobes is central fissure or sulcus, that is lying between the parietal and occipital lobes is parieto-occipital fissure and that demarcating frontal and parietal lobes from the temporal lobe is lateral or Sylvian fissure. Each cerebral hemisphere is with a fluid-filled cavity called lateral ventricle or paracoel.

Two cerebral hemispheres are interconnected by thick band of transverse nerve fibres of white matter called corpus callosum. The peripheral portion of each cerebral hemisphere is formed of grey matter and is called cerebral cortex, while deeper part is formed of white matter and is called cerebral medulla. Cerebral cortex is the highest centre for many sensations and activities and is with a number of sensory areas. Cerebral cortex 2-4 mm thick.

Histology of cerebrum : The whole brain possess grey matter outside and white matter inside around ventricle.

- (i) **Grey matter**: In cerebrum grey matter is very much developed, it is on an average 2-4 mm. thick but at poles its thickness is 1.3 mm. It is thickest at pre central gyrus (4.5 mm thick). Grey matter of cerebrum is called cortex or pallium. Phyllogenetically or evolutionarily cortex is divided into 3 parts –
- (a) Allocortex or paleocortex: It is the cortex of olfactory area of frontal lobe and olfactory bulbs. In lower vertebrates (cartilagenous fish) olfactory lobes occupy most of the part of cerebrum. So in these animals sense of olfaction is very-very much developed. Sense of olfaction is oldest sense.
 - (b) Mesocortex: It is relatively not much older in development.
- (c) Neocortex or neopallium or isocortex or neencephalon: It is most recent cortex and is developed maximum only in human. It is in prefrontal cortex or prefrontal region (organ of mind), precentral and postcentral gyrus etc. The neocortex is having 6 layer of neurons while remaining cortex possess only 5 layers.

The cerebral cortex is having area of about 2200 cm² while the cranial cavity is only 1450 cm³, so to accommodate cerebrum there appears foldings in the cortex. The ridges are called gyrus (or gyri) or convolution while the depression are called sulcus (sulci in plural).

(ii) White matter: It is inner part of brain. White matter is aggregation of myelinated and unmyelinated axons of many neurons. Its fibres are divided into 3 categories:

- (a) **Commissural fibres**: These neurons connect gyri of 2 hemispheres, such as corpus callosum. habenular commissure, anterior commissure, posterior commissure.
 - (b) Associate fibres: They connect gyri of same hemisphere.
- (c) Projection neuron: They are infact ascending and descending nerve tract, they connect one part of brain to another part of brain or to spinal cord. (In spinal cord they were called as column).

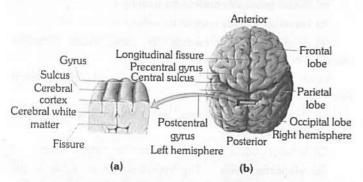

Fig: 5.6-5 (a) Details of gyrus, sulcus and fissure, (b) Posterior superior view of cerebrum

Associated structures of cerebrum: Cerebrum has following specific structure.

- (i) Sub cortex: Nuclei on white matter. It is cluster of grey neurons in depth of white matter, they are formed in whole brain and are named differently.
- (ii) Basal ganglia or central nucleus: These are several groups of nuclei in each cerebral hemisphere.

Corpus striatum: Corpus striatum is the largest nucleus, consist of caudate nucleus and lenticular nucleus. The lenticular nucleus is sub-divided in putamen (outer shell) and globus pallidus (ball). Other structure, functionally linked to and some times considered part of basal ganglia are:

(a) Claustrum: It is the name given to grey matter present between insula and putamen.

- (b) Epistriatum or Amygdaloid body: It is structure present at the end of caudate nucleus.
 - (c) Red nucleus and substantia nigra of mid brain.
 - (d) Sub thalamic nuclei of diencephalon.

Fig: 5.6-6 Basal ganglia

Function of basal ganglia

- (i) Caudate and putamen control large automatic movements of skeletal muscle like swinging of arm while walking.
- (ii) Globus pallidus control muscle tone for specific body movements.
- (iii) **Corpus callosum:** It is the band of white neurons present between both cerebral hemisphere and connect them on medial surface. It is present only in mammal. It has anterior part genu, middle part trunchus and last part splenium.

Below corpus callosum there are two fused band of white neurons called fornix. There anterior part is called column and posterior part is called crura. Between column and genu a membrane is called septum lucidum or septum pellucidum. Septum lucidum encloses a space called V_5 or Pseudocoel, because it is not possessing C.S.F. i.e. why it is called pseudocoel.

(iv) Limbic system: Limbic system present on inner border of cerebrum and floor of diencephalon, It is also called emotional brain or animal brain. Limbic system controls emotion, animal behaviour like chewing, licking, sniffing, docility, tameness, affection (animals) rage, pain, pleasure, anger, sexual feelings, fear, sorrow grooming. It has following structure —

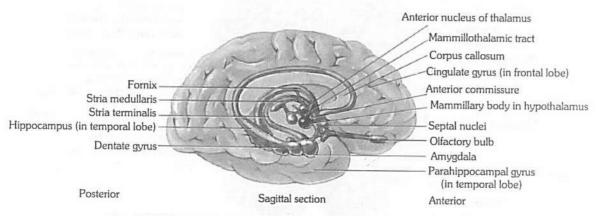

Fig: 5.6-7 Components of limbic system and surrounding structure

- (a) Cingulate gyrus: It is a region of pre central gyrus.
- (b) Hippocampal gyrus: It is a region of temporal lobe near colossomarginal sulcus. These two structure are combinely called limbic lobe.
 - (c) Amygdaloid body: It is the end of caudate nucleus.
- (d) **Olfactory bulb**: They are on the inferior anterior surface of brain. Olfactory nerve ends in these bulb.
- (e) **Mammillary body**: They are found in hypothalamus. Olfactory bulb and mammillary body both are centre of olfaction.
- (f) **Dentate gyrus**: Is in between hippocampus and parahippocampale.
- (g) Anterior nucleus of thalamus is located in floor of lateral ventricle.

Diencephalon: Diencephalon cavity is called, III ventricle or diocoel the thin roof of this cavity is known as the epithalamus, the thick right and left sides as the thalami, and floor as the hypothalamus.

(i) **Epithalamus**: It forms the roof of third ventricle. The epithalamus is not formed of nervous tissue. It consists of piamater

only. Hence, it is of relatively little significance as a nerve centre. Its anterior part is vascular and folded. It is called anterior choroid plexus. Behind this plexus, the epithalamus gives out a short stalk, the pineal

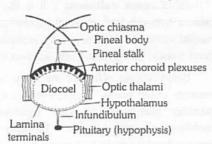

Fig: 5.6-8 Diencephalon

stalk which bears a small, rounded body, the pineal body, at its tip, and paired right and left habenular nuclei (olfaction or smell).

- (ii) **Thalamus**: A pair of mass of grey matter forms the superior part of lateral walls of the third ventricle. It measures 3 cm in length and comprises 80% of diencephalon. The thalamus is principal relay station for sensory impulses that reach the cerebral cortex from spinal cord, brain stem, cerebellum. It also allows crude appreciation of some sensations such as pain, temperature, and pressure. Certain nuclei in the thalamus relay all sensory input to cerebral cortex. These include the
 - (a) Medial geniculate nucleus for hearing.
 - (b) Lateral geniculate nucleus for vision.
- (c) Ventral posterior nucleus for taste, touch, pressure, vibration, heat, cold, and pain.

Other nuclei are centres for synapse in somatic motor system their include.

- (a) Ventral lateral nucleus and ventral anterior nucleus (voluntary motor actions).
 - (b) Anterior nucleus concerns with emotions and memory.
- (iii) Hypothalamus: The hypothalamus is visible in the ventral view of the brain and forms the floor of diencephalon. Hypothalamus also gives a nervous process called infundibulum (forms pars nervosa) which meets a rounded non-nervous pharyngeal outgrowth called hypophysis. Both collectively form master gland called pituitary body. A stalked outgrowth of infundibulum combines with a pouch-like epithelial outgrowth (Rathke's pouch) of the roof of embryonic mouth (= stomadeum), forming a pituitary gland or hypophysis. Which secretes a number of hormones. In front of hypothalamus, there is crossing of two optic nerves called optic chiasma. Behind the hypothalamus, there is one pair of small, rounded, nipple-like bodies called mammilary bodies or corpora mammillares. The hypothalamus consists of many masses of grey matter, called hypothalamic nuclei, scattered in the white matter.

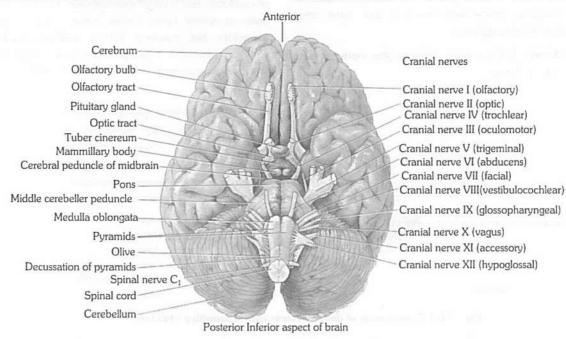

Fig: 5.6-9 Ventral view of brain

UNIVERSAL BOOK DEPOT 1960

In man and some other mammals, most fibres of optic nerves cross, but some fibres do not cross and innervate the eyes of their own respective sides. This arrangement enables man and these mammals to have a binocular vision. Rabbits simply have a monocular vision.

Pineal gland is a pine cone-shaped gland. It is located in the centre of brain with which it loses all nervous connection after birth. It is innervated by sympathetic nerves. It has a photosensory role in amphibian and primitive reptiles and is called 'Third eye'. Pinealocytes secretes melatonin. Mammalian pineal does not act as photoreceptor but it produces the hormone called melatonin which is anti FSH, and anti LH. It inhibits reproductive function. Melatonin secretions decrease after puberty.

Functions of fore brain

- (i) Olfactory lobe: It is centre of smell.
- (ii) $\boldsymbol{Cerebrum}: Cerebral cortex is made up of grey matter and differentiated into$
- (a) Sensory and associated area confirm, recognise and evaluate for shape, colour, sound, taste and smell for sensory cells in relation with object.
- (b) Broca's area: Known as sensory speech area or motor speech area. Translate thought into speech. Located into frontal lobe towards left side. It is associated with language area and also

interprete translation of written words into speech. Damage or injury in Broca's area (sensory or motor speech area) may result.

Aphasia(Inability to speak), Word deafness, Word blindness.

Table: 5.6-1 Important areas in the human brain

Area	Location	Function
Premotor area	Frontal lobe	The highest centre for involuntary movements of muscles and ANS.
Motor area	Frontal lobe	Controls voluntary movements of the specific muscle
Broca's area	Frontal lobe	Motor speech area (Translation of thought and written words into speech)
Somesthetic area	Parietal lobe	Perception of general sensation like pain, touch and temperature
Auditory area	Temporal lobe	Hearing (Interprets characteristics of sound such as pitch and rhythm.
Olfactory area	Temporal lobe	Sense of smell
Wernicke's area	Temporal lobe	Understanding speech, written and spoken
Gustatory area	Parietal lobe	Sense of taste
Visual area	Occipital lobe	Sensation of light

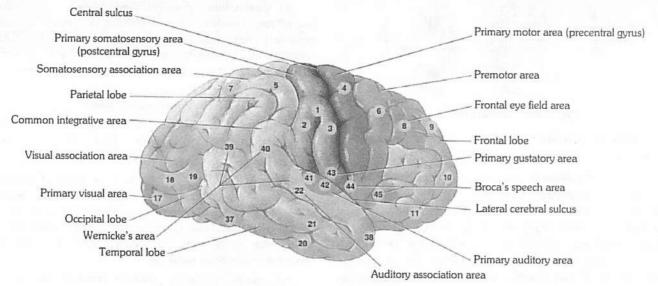

Fig: 5.6-10 Functional areas of the cerebrum

- (c) **Cerebrum is a centre for –** Intelligence, Emotion, Will power, Memory, Consciousness, Imagination, Experience, Knowledge, Reasoning, Voluntary controls, Weeping and laughing, Micturition, Defecation.
- \square If cerebrum is removed animal becomes simple reflex animal.
- (iii) Diencephalon is a centre for :
- (a) Carbohydrate metabolism
- (b) Fat metabolism
- (c) It relays impulses from posterior region of brain and also to posterior region of brain.

- (d) It secretes neurohormone
- (e) Form part of pituitary gland
- (f) Secrete cerebrospinal fluid
- (iv) **Hypothalamus is a centre for** Hunger, Thirst, Sweating, Sleep, Fatigue, Temperature, Anger, Pleasure, love and hate, Satisfaction.
 - It is also centre to release factors for endocrine glands.
 - ☐ It also control A.N.S (autonomic nervous system)
- ☐ Centres for regulation of parasympathetic (cranio-sacral) activity. When stimulated, it causes slowing down of heart beat, contraction of the visceral muscles.
- (2) Mid brain or mesencephalon: Extends from pons to diencephalon, contain both white and grey matter. Posterior portion of mid brain is called tectum. It is also completely covered by cerebral hemisphere. It is formed of two parts —
- (i) **Optic lobes**: These are one pair, large sized lobes present on dorsal side. Each is divided transversely into upper and larger superior colliculus and lower and smaller inferior colliculus. So there are four optic lobes, so called optic quadrigemina (only in mammals). In frog these are known as bigemina. **Valve of vieussens**. It joins the optic lobe with cerebellum.
- (a) Superior optic lobe or superior colliculus: They are concerned with reflex action of eye, head and neck in response to visual stimulus.

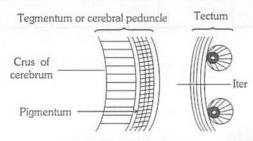

Fig: 5.6-11 Lateral view

- (b) **Inferior colliculus**: They are concerned with movement of head and trunk in response to hearing stimulus.
- (ii) Cerebral peduncle (crura cerebri): They are the pair of thick bands of longitudinal nerve fiber present on the floor or ventral side of mid brain. The dorsal part of cerebral peduncle (white matter) is called Tagmentum while most ventral part (grey matter) is called crura cerebrae or crus of cerebrum. Dorsal thick wall of mid brain is known as optic tectum. Iter is between tegmentum and tectum. Cerebral peduncle are infact possessing ascending and descending tracts, connecting upper and lower region of brain.

In white matter of cerebral peduncle these are following sub cortical structure

(a) Red nucleus or rustrum nucleus: They are red because of rich blood supply and iron containing pigment or haemoglobin. Function with basal ganglia and cerebellum to coordinate muscular movement.

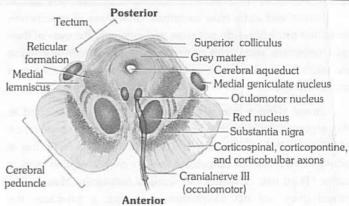

Fig: 5.6-12 T.S. of midbrain

- (b) **Substantia nigra**: It is black because of much deposition of melanin.
- (c) Occulomotor nucleus: It is origin point of 3rd cranial nerve (occulomotor) from this region 4th (Trochlear) nerve also originates.

Functions of Mid brain

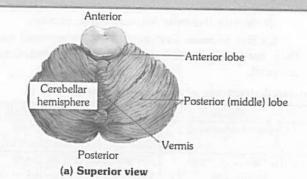

- (i) Pair of anterior optic lobes (which are also known as superior colliculi) is related with vision.
- (ii) Pair of posterior optic lobe (known as inferior colliculi) related with auditory function.
- (iii) These act as coordination centres between hind and fore brain.
- (3) **Hind brain**: Hind brain consists of (i) cerebellum and (ii) medulla oblongata (iii) Pons varolii.
- (i) **Cerebellum** (Sandwitched brain): Cerebellum is second largest portion of brain which lies posterior to medulla and pons and inferior to posterior portion of cerebrum. Cerebellum is separated by cerebrum by a transverse fissure and by an extension of cranial dura mater called tentorium cerebelli. Cerebellum is butterfly shape consist of:
 - (a) The central constricted area is vermis
- (b) A lateral wings or lobes called cerebellar hemispheres with anterior and posterior lobe (govern skeletal muscle movement).
 - (c) The flocculo nodular lobe (sense of equilibrium).

Between cerebellar hemisphere is extension of cranial dura mater called falx cerebelli. The superficial layer of cerebellum, called cerebellar cortex, consist of grey matter in series of parallel ridges called folia. Deep to grey matter is white matter tree called 'Arbor vitae' or tree of life. Cerebellum is attached to brain stem by three paired cerebellar peduncles –

- (a) Inferior cerebellar peduncle between cerebellum and medulla with sensory/motor fibre.
- (b) Middle cerebellar peduncle between cerebellum and pons with sensory axon.
- (c) Superior cerebellar peduncle between cerebellum and mid brain, mainly with major fibre.

Cerebellum receives sensory impulses from proprioceptors in muscle, joint, and tendons, coordinate skeletal muscle contractions and also regulate posture and balance.

UNIVERSAL BOOK DEPOT 1960

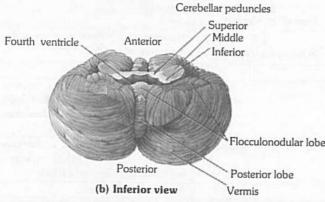

Fig: 5.6-13 Structure of Cerebellum

(ii) Medulla oblongata

Medulla oblongata is the hindest and posterior most part of brain. Cavity is known as IVth ventricle (metacoel) which is continuous with central canal of spinal cord. It has a pair of lateral Foramina of Luschka and a median foramen magendie. Cerebrospinal fluid come in contact by these apertures from internal cavity of the brain to outer fluid of meninges. A arrangement on its ventral surface there are buldgings of ascending and descending tract which are called pyramids. On the ventral surface these pyramids cross each other which is called decussation of pyramids. On the dorsal side of medulla there are two nuclei which are called nucleus gracilis (long) and nucleus cuneatus. On floor of V_4 there is groove called calamus scroptosious.

In the medulla oblongata, most of the sensory and motor fibres cross from one side to the other. Thus, the left cerebral hemisphere controls the right side of the body and *vice versa*. The reason for this is not known. The lower end of medulla passes into the spinal cord. There is no demarcation between the two. However, the medulla is considered to start at the level of the foramen magnum of the cranium. Medulla contain nuclei of origin of 5 pairs of cranial nerves, VIII, IX, X, XI and XII. VIII – vestibulocochlear nerve is concerned with hearing and equilibrium. (There are also nuclei for vestibular branch of VIII in pons).

(iii) Pons Varolii: An oval mass, of white matter called the pons varolii, lies above the medulla oblongata. It consists mainly of nerve fibres which interconnect as bridge connecting spinal cord with brain and parts of brain with each other. Pons also with pneumotaxic area and apneustic area. Together with medullary rhythmicity area, they help in controlling respiration.

Functions of hind brain

Cerebellum -

(i) Poorly developed in frog but well developed in mammal.

- (ii) It is centre for co-ordination of muscular movement.
- (iii) It is primary centre for balancing, equilibrium, orientation.

Medulla oblongata contain centre for -

- (i) Heart beats
- (ii) Respiration
- (iii) Digestion
- (iv) Blood pressure
- (v) Gut peristalsis
- (vi) Swallowing of food
- (vii) Secretion of gland
- (viii) Involuntary function e.g. vomiting, coughing vasoconstrictor, vasodilater, sneezing, hiccouping.
 - (ix) It control urination, defecation.
- (x) The cardiovascular centre regulate rate, force of heart beats.
- (xi) Medullary rhythmicity area adjust basic rhythm of respiration.

Cavities or ventricles of the brain

The ventricles consist of four hollow fluid filled space inside the brain and same duct for connection between these ventricle.

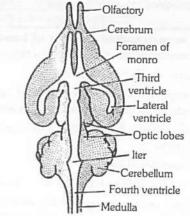

Fig: 5.6-14 Ventricles of brain of rabbit

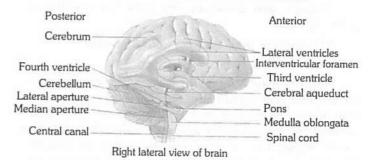

Fig: 5.6-15 Diagram showing ventricles of human brain

- (1) Olfactory lobe Rhinocoel
- (2) Cerebrum I and II ventricle or lateral ventricle or paracoel.
- (3) Foramen of monro: I and II ventricle communicating with IIIrd ventricle by foramen of monro. They are two in human and single in rabbit and frog.
 - (4) Diencephalon: Third ventricle or Diocoel.

(5) Iter or cerebral aquiduct or aquiduct of sylvius: It is very narrow cavity between III and IV ventricle.

(6) Optic lobe : Optocoel(7) Cerebellum : Solid.

(8) Medulla oblongata: 4th ventricle or metacoel.

Cavities of brain and spinal cord are modified neurocoel. They are lined by low columnar ciliated epithelium called ependyma.

Table: 5.6-2 Subdivisions, parts and associated structures of a vertebrate brain

Divisions	Subdivisions	Parts	Cavity	Associated streutures
	(1) Telencephalon	Rhinencephalon	I Ventricle (Rhinocoel)	Olfactory bulbs, Olfactory tracts, Olfactory lobes, Palaeocortex on pallium
	10,000	Cerebral hemispheres	II or Lateral Ventricles (Paracoels) Formen of Monro	Corpora striata or basal ganglia, Corpus callosum, Neocortex on pallium, Paraphysis
(I) Prosencephalon (Forebrain)	(2) Diencephalon	Epithalamus (roof)	III Ventricle (Diocoel)	Habenulae, Pineal apparatus, Parapineal or parietal
		Thalamus (sides) superior		
		Hypothalamus (floor), Inferior side		Hypothalamic nuclei, Optic chiasma, Median eminence, Infundibular stalk, Pituitary, Saccus vasculosus, Mamillary bodies, Anterior choroid plexus
(II) Mesencephalon (Midbrain)		Crura cerebri (floor)	Iter or cerebral aqueduct	Corpora quadrigemina (superior colliculi, inferior colliculi), Tectum, substantia nigra and red nuclei.
(III) Rhombencephalon	(1) Metencephalon	Cerebellum		Trapezoid body, Pons
(Hind brain)	(2) Myelencephalon	Medulla oblongata	IV Ventricle (Metacoel)	Restiform bodies, Pyramids

Salient or mammalian features of human brain: The salient or mammalian features in the human brain are –

- (1) Relatively small, solid olfactory lobes.
- (2) Very large cerebral hemispheres divided into lobes and with highly folded surface, with cerebral cortex of grey matter.
- (3) Corpus callosum interconnecting the cerebral hemispheres only found in eutheria.
 - (4) Very small pineal body.
 - (5) A pair of mammillary bodies joined to hypothalamus.
- (6) Relatively small, solid optic lobes divided into 4 corpora quadrigemina.
- (7) Large, solid cerebellum, with highly folded surface and divided into lobes.
 - (8) Pons varolii present anterior to the cerebellum.

Spinal cord

Present in spinal canal or vertebral canal of vertebral column. It is extended from foramen magnum to II lumbar vertebra. In new born infants, extend to 3 or 4 lumbar vertebra. Spinal cord is swollen in cervical and lumbar region which are called cervical and lumbar enlargement. The length of spinal cord ranges from 42 to 45 cm. Its diameter is about 2cm.

Structure of spinal cord

- (1) **Conus medullaris**: It is last tapering end of spinal cord, its ciliated central canal is called Vth ventricle.
- (2) Cauda equina: A horse tail-like collection of roots of spinal nerves at inferior end of the spinal cord. Some spinal nerves arise from inferior part of cord do not leave vertebral column at same level as they exit from spinal cord. The roots of these nerves angle inferiorly in vertebral canal from end of spinal cord like wisps of hair.

- (3) Filum terminale: It is extension of piamater below conus medullaris upto coccyx. In frog spinal cord also extends upto end of vertebral column.
- (4) Cisterna terminalis: It is last dilation of subarachnoid space below 1st lumbar vertebra. It is a proper site for lumbar puncture or spinal tap, which is done to drain C.S.F out (5 to 10 ml). This C.S.F is used in diagnosing many diseases of CNS like meningitis, encephalitis, inter cranial pressure, meningococcal infection etc.
- (5) **Meninges:** Like brain, spinal cord is also enclosed within three membranes. In this case duramater does not remain attached with the vertebra, instead there is a space between duramater and vertebra called epidural space. The epidural space is filled with a fluid. The distribution of duramater and piamater in spinal cord is the same as that of brain.

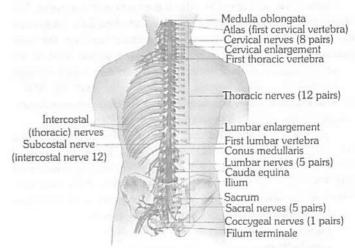

Fig: 5.6-16 External anatomy of the spinal cord and the spinal nerves

UNIVERSAL

The cross section of spinal cord reveals the following

- (1) Central canal: In the centre of spinal cord, there is a canal called central canal. It is filled with cerebrospinal fluid. central canal is continuous with 4th ventricle of medulla oblongata.
- (2) Dorsal fissure: In the mid dorsal line, there is a groove extending throughout its length.
- (3) Ventral fissure: It is also a groove situated in the mid ventral line throughout the length of spinal cord.
- (4) Dorsal septum: It is a partition extending from dorsal fissure to central canal.
- (5) Grey matter: It lies around the central canal in the form of a butterfly and sub-divided into 3 horns, surrounded by white matter.

- (6) Dorsal horns: It is like horn of grey matter on the dorsal side.
- (7) Ventral horns: On the ventral side of the grey matter are horn like structures the ventral horns.
- (8) Lateral horns: These are horns on the lateral side of grev matter.
- (9) White matter: White matter is present around grey matter. Dorsal and ventral horn, divide white mater into 3 broad area on each side -
 - (i) Anterior (ventral) white columns
 - (ii) Posterior (dorsal) white columns
 - (iii) Lateral white columns.

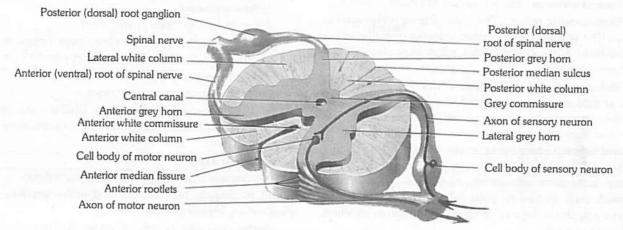

Fig: 5.6-17 T.S. of the thoracic spinal cord of mammal

Reflex action: Reflexes are fast predictable, automatic responses to change the environment. First of all Marshal Hall (1833) studied the reflex action. Best and Taylor defined reflex action "simplest form of irritability associated with the nervous system is reflex actions or a reflex reaction is an immediate involuntary response to a stimulus." The reflex actions are involuntary actions because these are not under the conscious control of the brain. Central nervous system is responsible for the control of reflex action.

Reflex arc is formed by the neurons forming the pathway taken by the nerve impulses in reflex action. The simplest reflexes are found in animals involving a single neuron and the following pathway -

Stimulus → Receptor — Neuron → Effector → Response

- (1) Component of reflex action: The whole of the reflex includes five parts -
- (i) Receptor organs: Receptors are windows of the body or guards of the body. These are situated on all, important organs, for example - eyes, nose, ear, tongue, integument etc. These perceive the stimuli from out side the body.
- (ii) Sensory neurons : These are also termed afferent neurons. These carry the stimuli from receptors to spinal cord. These neurons are situated in the ganglion on the dorsal side of spinal cord grey matter or brain stem.

- (iii) Association neurons or Integrating centre: These are also called intermediate neurons or interstitial neurons. These are found in spinal cord. They transfer the impulses from sensory neurons to motor neurons. Association neurons forms monosynaptic and polysynaptic reflex arc.
- (iv) Motor neurons: These are situated in the ventral horn of spinal cord. These carry the impulses to effector organs.
- (v) Effector organs: These are the organs, which react and behave in response to various stimuli, for example - muscles and glands.

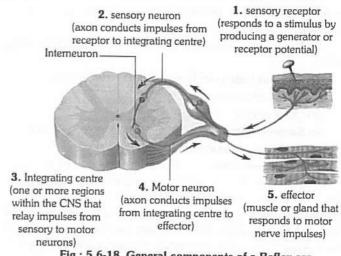

Fig: 5.6-18 General components of a Reflex arc

- (2) **Mechanism of reflex action**: The time taken by a reflex action is too short, for example in frog it is 0.3 metre per second and in man 5-120 metre per second. Whenever, a part of the body is stimulated by any stimulus, for example pin pricking, then the stimulus is converted into impulse. This impulse is perceived by the dendrites of sensory neurons. From here, the stimulus reaches the spinal cord through axonic fibres. In the spinal cord, this stimulus passes through synaptic junctions and reaches the intermediate neurons, from where this stimulus reaches the effector organs through motor nerve fibres. As soon as the stimulus reaches the effector organs, it is stimulated and that part of the body is immediately withdrawn. The whole reflex action takes place so rapidly and quickly that we know it when it is completed.
 - (3) Type of reflexes: The reflexes are of following types -
- (i) Monosynaptic reflex: This is the simplest reflex found in vertebrates. The sensory neuron synapses directly on to the motor neuron cell body. In this case the reflex action takes place without the involvement of brain.
- (ii) Polysynaptic spinal reflex: This has at least two synapses situated within the spinal cord. It involves a third type of neuron also the internuncial or inter-mediate relay neuron. The synapses take place between the sensory neuron and intermediate neuron, and between intermediate neuron and the motor neuron. These two reflex arcs allow the body to make automatic, involuntary, homeostatic adjustments, to changes in the external environment, such as the iris pupil reflex and balance during locomotion, and also in the internal environment such as breathing rate and blood pressure.
- (iii) Polysynaptic spinal/brain reflexes: In this case the sensory neuron synapses in the spinal cord with a second sensory neuron, which passes to the brain. The latter sensory neurons are part of the ascending nerve fibre tract and have their origin in preintermediate neuron synapse. The brain is capable of identifying this sensory information and stores it for further use. The motor activity may be initiated by the brain anytime and the impulses are transmitted down the motor neurons in descending nerve fibre tract, to synapse directly with spinal motor neurons in the postintermediate synaptic region.
- (iv) **Simple reflex**: Simple reflex is also known as unconditioned reflex. It is inborn, unlearned, reflex to a stimulus. Simple reflex is mostly protective in function. Example of simple reflex are
- (a) Knee jerk Tendon of patella tapped, also called patellar reflex.
 - (b) Corneal reflex (blinking reflex) closing of eyelids.
 - (c) Rapid withdrawal of hand while burned or pricked.
 - (d) Quick recovery of balance while falling.
 - (e) Scratch reflex of frog in pithed frog with acetic acid.
 - (f) Coughing, sneezing and yawning.
- (v) Acquired reflex: Acquired reflex is also known as conditioned reflex. It is not inborn, but acquired and dependent on past experience, training and learning. Demonstration of conditioned reflex was first made by Russian physiologist Ivan Petrovitch Pavlov (1846-1936) in hungry dog. Pavlov rang the bell while feeding dog, thus associated the unconditioned response with additional stimulus. Examples of conditioned reflex are

learning of dancing, cycling, swimming, singing,, driving, etc. These actions are under cerebral control during learning.

Peripheral nervous system

It is formed of a number of long, thin, whitish threads called nerves extending between central nervous system and body tissues. Each nerve is formed of bundles of nerve fibres, fasciculi, held together by connective tissue and surrounded by a white fibrous connective tissue sheath called epineurium.

The nerve fibres are classified into two categories on the basis of presence or absence of myelin (white fatty) sheath.

- (1) Medullated or Myelinated nerve fibres.
- (2) Non-medullated nerve fibres.
- On the basis of function, the nerves are of three types
- (1) Sensory nerve
- (i) It contains only sensory nerve fibres.
- (ii) It conducts nerve impulses from sense organs to CNS to produce sensation. e.g. Optic nerve, auditory nerve.
 - (2) Motor nerve
 - (i) It contains only motor nerve fibres.
- (ii) It conducts nerve impulses from CNS to some muscles or glands to control their activities. *e.g.* Occulomotor nerve, hypoglossal nerve.
 - (3) Mixed nerve
 - (i) It contains both sensory and motor nerve fibres.
- (ii) It conducts both sensory and motor impulses. e.g. All spinal nerves, trigeminal nerve.

On the basis of their origin, nerves are of two types

- (1) Cranial or cerebral nerves which either arise from or end into brain.
 - (2) Spinal nerves which arise from spinal cord.

Cranial nerves

- (1) 10 pairs of cranial nerves are present in an anamniote (fishes and amphibians).
 - (2) Number of cranial nerves found in frog is ten pairs (20).
- (3) 12 pairs of cranial nerves are present in an amniote (reptiles, birds and mammals).
- (4) Number of cranial nerves found in rabbit and man is 12 pairs (24).
- (5) The first 10 pairs are common for frog and rabbit. The additional pairs found in rabbit are spinal accessory and hypoglossal.
- (6) The smallest cranial nerve is trochlear in human beings, but in all animals smallest cranial nerve is abducens.
- (7) The largest cranial nerve is trigeminal in human beings but vagus is largest cranial nerve in all animals.
 - (8) Vagus supplies the regions other than head.
 - (9) The sensory cranial nerves are

I Olfactory – Smell II Optic – Vision

VIII Auditory – Hearing and equilibrium

- (10) The motor cranial nerves are : III, IV, VI, XI and XII.
- (11) Extraocular muscle nerves are : III, IV and VI.
- (12) The mixed cranial nerves are: V, VII, IX and X (4 pairs).
- (13) Number of cranial nerves in snake (Amniota) 10 pairs.

Table: 5.6-3 Cranial nerves of mammal at a glance

	Name	Nature	Origin	Distribution	Function
[1]	Olfactory Nerves	Sensory	Olfactory lobe	Sensory epithelium of olfactory sacs	Receive stimuli from the sensory epithelium of olfactory sac and carry them to olfactory lobes
[11]	Optic nerves	Sensory	In retina of eye	Lateral geniculate nuclei of thalamus	Stimulus of light is carried to optic occipital lobe of cerebral cortex.
[111]	Occulomotor nerves	Motor	Crura cerebri (mid brain)	Eye ball muscles like superior rectus, medial rectus, inferior rectus and inferior oblique. except superior oblique muscle and external rectus	Movement of eye lids and eye ball.
[IV]	Trochlear nerves	Motor	From in between the optic lobes and cerebellum	Superior oblique muscle of eye ball	Movement of eye ball
[V]	Trigeminal nerves	Mixed	From the gassarion ganglia situated on the lateral side of pons		
	(i) Ophthalmic nerve	Sensory		Skin of lips, upper eye lid, lacrimal, gland	California de la companya del companya del companya de la companya
	(ii) Maxillary	Sensory	"	Upper lip, skin of nose, lower eye lid. Upper teeth.	Carry the stimuli from these organs to brain
	(iii) Mandibular nerve	Mixed	, , , , , , , , , , , , , , , , , , , ,	Lower lip and skin of jaw	Carry the stimuli from these organs to brain
[VI]	Abducens nerves	Motor	Pons	Eye muscles external rectus	Movement of eye ball
[VII]	Facial nerves	Mixed	Pons		
	(i) Palatinus	Sensory		In the roof of mouth cavity	Carry the impulses from roof of mouth cavity
	(ii) Hyomandibular	Motor		Muscles of lower jaw, muscles of neck and pinna (external ear)	Carry the impulses from brain musices of lower jaws, neck and pinna.
	(iii) Chordatympani	Mixed	a	In salivary glands and taste buds	Receives the stimuli from the taste buds and carry the stimulus to salivary gland.
[VIII]	Auditory nerves	Sensory	Medulla, pons		
	(i) Vestibular nerve	"		Semicircular canals, saccule, utricle.	Receives impulses from the internal ear and carry to brain for equilibrium
	(ii) Cochlear nerve	- 17		Cochlea	Impulses associate with hearing.
[IX]	Glossopharyngeal nerve	Mixed	In medulla	Taste buds present in tongue and muscles of oesophagus	Secretion of saliva, taste muscle sense (proprioception)
[X]	Vagus nerve	Mixed	Arising from medulla, 9th and 10th cranial nerves unites to form vagus nerve but become separate and divide into branches		
	(i) Superior laryngeal nerve	Motor	region of the Marian	Glottis, trachea, lung muscle	(1) Smooth muscles contraction and relaxation.
	(ii) Recurrent laryngeal nerve	Motor		Glottis, trachea, lung muscle.	(2) Secretion of digestive juice.(3) Muscle sense (proprioception)(4) Sensation of visceral organs.
	(iii) Cardiac nerve	Motor		Heart Muscles	From brain to heart muscles
	(iv) Pneumogastric	Motor	Noval v o cej vod Smrtis mojeti po	In the abdominal cavity, in stomach and lungs.	Carry impulse from these organs to brain and from brain to muscles of these organs.
	(v) Depresser nerve	Motor	Manualla La ndon de Manual de Manua	Diaphragm	Carry the impulse to diaphragm
[XI]	Spinal accessory	Motor	Medulla	Muscles of neck and shoulders, voluntary muscles of pharynx, larynx, and soft palate.	Swallowing movements, movement of head.
[XII]	Hypoglossal nerve	Motor	Medulla	Muscles of tongue and neck	Movement of tongue during speech, and swallowing, proprioception (Muscle sense).

Spinal nerves: Spinal nerves arise from grey matter of spinal cord. There are 31 pairs of spinal nerves in man (37 pairs in rabbit). All spinal nerves are mixed. The spinal nerves in man are divided into 5 groups.

- (1) Cervical (C) → 8 pairs in Neck region
- (2) Thoracic (T) → 12 pairs in thoracic region
- (3) Lumbar (L) → 05 pairs upper part of abdomen
- (4) Sacral (S) → 05 pairs lower part of abdomen
- (5) Coccygeal (CO) → 01 pairs represent the tail nerves

Total = 31 pairs

Number of spinal nerves in frog is 10 pairs. In some frog like Rana tigrina, 10th pair may be reduced or absent. The first pair of spinal nerves in frog is hypoglossal. The last pair of cranial nerves of mammals has the same name. Brachial plexus is formed by 2nd and 3rd spinal nerves in frog. Sciatic plexus is formed by 7, 8 and 9 spinal nerves in frog. Glands of Swammerdam are calcareous glands found at the places of emerging of spinal nerves in frog.

Spinal nerve formula can be written as $-C_8$, T_{12} , L_5 , S_5 , CO_1 , Spinal nerves exit via intervertebral foramen. Each spinal nerve arises from spinal cord by 2 roots

- (1) Dorsal (= Afferent = Sensory = Posterior) root is a continuation of dorsal horn and is formed of grey matter. It presents a ganglionic swelling in middle, called dorsal root ganglion. These transmit sensory nerve impulses from the sense organs to spinal cord (touch, pain, temperature). They activate involuntary reflexes.
- (2) Ventral (= Efferent = Motor) root are continuation of ventral horn and is also formed of grey matter. No ganglion are present. It is formed of only efferent nerve fibers. They transmit motor nerve impulses to effector organs e.g., glands and muscles. Each spinal nerve has 4 branches –
- (i) Ramus dorsalis: Supplies to skin and muscles of dorsal side.
- (ii) Ramus ventralis: Supplies to skin and muscles of ventral and lateral sides and also to upper and lower limbs. Ventral root of certain spinal nerve form 5 nerve plexi on either side, i.e., cervical, thoracic, lumbar, sacral, caudal.
- (iii) Ramus communicans: It joins sympathetic ganglion of autonomic nervous system.
 - (iv) Meningeal branch: Vertebra, vertebral blood vessel.

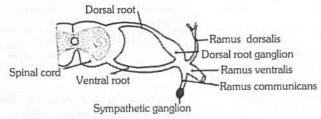

Fig: 5.6-19 Origin and distribution of spinal nerve

Autonomic nervous system

Autonomic nervous system was discovered by Langley. Autonomic nervous system (ANS) automatically regulates the activities of smooth muscles, cardiac muscles and glands. This coordination is involuntary. Autonomic nervous system usually operates without conscious control. Autonomic nervous system is entirely motor. All autonomic axons are efferent fibres. Autonomic nervous system is regulated by centres in brain like cerebral cortex, hypothalamus and medulla oblongata. Autonomic fibres release chemical transmitters at synapse. On the basis of the transmitter produced, these fibres may be classified as cholinergic or adrenergic. Cholinergic fibres release acetylcholine. Adrenergic fibres produce norepinephrine (noradrenaline), also called sympathetin.

Nature of autonomic control: The autonomic nervous system regulates and co-ordinates such vital involuntary activities like heart beat, breathing, maintenance of the composition of body fluids (= homeostasis) and body temperature, gut peristalsis, secretion of glands, etc. Autonomic nervous system consists of two divisions –

- (1) Sympathetic ANS (Thoracolumbar out flow)
- (i) Thoraco Lumbar out flow (all thoracic + 3 lumbar)
- (ii) Preganglionic nerve small.
- (iii) Post ganglionic nerve long.
- (iv) Preganglionic nerve secrete acetyl choline.
- (v) Postganglionic nerve secrete sympathetin. (norepinephrine)
 - (vi) It shows sympathy (generally increase the function).
 - (vii) Expenditure of energy takes place.
- (viii) It increase defence system of body against adverse condition.
 - (ix) It is active in stress condition, pain, fear and anger.
 - (2) Parasympathatic ANS (Cranio-sacral out flow)
- (i) ANS Cranio sacral outflow (cranial-III, VII, IX, X Nerves)-(sacral-II, III, IV Nerves)
 - (ii) Preganglionic nerve long.
 - (iii) Postganglionic nerve small.
 - (iv) Secrete acetyl choline only.
 - (v) It provide relaxation, comfort, pleasure, at the time of rest.
 - (vi) Restoration and conservation of energy takes place.
 - (vii) Collateral ganglia present in sympathetic nervous system.
- (viii) Horner's syndrome results from the damage of sympathetic trunk of one side.
- (ix) A patient of Horner's syndrome exhibits lack of sweating (on affected side), sunken eyes and constricted pupil.

Table: 5.6-4 Difference between sympathetic and Parasympathetic

S.No.	Name	Sympathetic	Parasympathetic
1.	Secretion	Acetyl choline and Sympathetin	Acetyl choline only
2.	Blood pressure	Increase	Decrease
3.	Blood vessel to skin	Constrict	Dilate
4.	Blood vessel to heart	Dilate	Constrict
5.	Blood vessel to lung and muscle	Dilate	Constrict
6.	Pupil	Dilate	Constrict
7.	Lacrimal gland	Stimulate	Inhibits
8.	Heart beat	Increase	Decrease
9.	Adrenal secretion	Stimulate	Inhibit
10.	Breathing and BMR	Increase	Decrease
11.	Nostrils	Dilate	Constrict
12.	Urinary bladder	Relax	Constrict
13.	Iris	Constrict	Dilate
14.	Salivary gland	Decrease	Increase
15.	Digestive gland	Decrease	Increase
16.	Gut peristalsis	Decrease	Increase
17.	Ejaculation	Increase	Decrease
18.	Bile	Decrease	Increase
19.	Renin (kidney)	Increase	Decrease
20.	Bronchi	Dilate	Constrict

Cutting of sympathetic or parasympathetic nerve to heart will not stop functioning of heart. Heart will beat but without any nervous control. Autonomic nervous system functions rapidly to alter visceral functions (3-5 seconds). It is activated mainly by centres located in spinal cord, brain stem and hypothalamus. Limbic cortex also influences its function often this system function via visceral reflexes *i.e.* sensory signal \rightarrow enter autonomic ganglia \rightarrow spinal cord \rightarrow brain stem \rightarrow or hypothalamus can elicit reflex responses back to visceral organs to control their activities.

Biochemical Aspect of Nervous Physiology

Nerve cells (= neurons): Irritability is a basic characteristic of the "living substance", i.e., the protoplasm. Consequently, every living cell becomes excited when stimulated. However, the nerve cells and muscle fibres are specialized excitable cells of body, capable of transmitting or conducting excitations along their membranes. Of these, muscle cells are further specialized for contraction while nerve cells are further specialized for receiving stimuli (as sensory or receptor cells) and transferring excitations from one to the other.

A typical neuron consists of a nucleated cell body (= cyton, soma or perikaryon), five to seven short, slender and branched (= arborized) dendrites, and a single, relatively thicker and longer fibrous axon. The latter is terminally branched into short telodendria. Each telodendron bears a terminal **knob** or **button**. Buttons of one neuron lie upon dendrites or cytons of adjacent neurons (figure), or upon muscle fibres or glands.

Nerve fibres: Although, all parts of a neuron transmit excitations (= impulses), but the transmission is always unidirectional. The dendrites and cytons usually constitute the impulse receiving parts which receive impulses directly from receptors, or from other adjacent neurons. The axons are specialized as fibres conducting impulses away from the receiving parts. Thus, the reaction or response impulses are always carried to the effectors by axons. That is why, the term 'nerve fibres' is usually applied to the axons. The latter are 0.1 mm to one or more (upto 10) metres long and about 0.025 m thick on an average.

Main properties of nervous tissue: The nervous tissue has two outstanding properties excitability and conductivity.

- (1) Excitability: It is the ability of the nerve cells and fibres to enter into an active state called the state of excitation in response to a stimulus. Excitation arises at the receptors on account of various stimuli such as light, temperature, chemical, electrical or pressure which constantly act on the organisms.
- (2) Conductivity: The excitation does not remain at the site of its origin. It is transmitted along nerve fibres. The transmission of excitation in a particular direction is called conductivity.

Definition of nerve impulse : A wave of reversed polarity or depolarization (action potential) moving down an axon is called a nerve impulse.

Mechanism of conduction of nerve impulse

Most accepted mechanism of nerve impulse conduction is ionic theory proposed by Hodgkin and Huxley. This theory states that nerve impulse is an electro-chemical even governed by differential permeability of neurilemma to Na^+ and K^+ which in turn is regulated by the electric field.

- (1) Transmission of nerve impulse along the nerve fibre
- (i) Polarization (Resting membrane potential-RMP) : In a resting nerve fibre (a nerve fibre that is not conducting an impulse), sodium ions (Na+) predominate in the extracellular fluid, whereas potassium ions (K^+) predominate in the intracellular fluid (within the fibre). Intracellular fluid also contains large number of negatively charged (anions) protein molecules. Na^+ are 10 times more outside the neuron and K^+ ions are 25 times more inside the cell. Thus it makes a considerable difference between the ion concentration outside and inside the plasma membrane. It also causes a difference in electrical charges on either side of the membrane. The plasma membrane is electrically positive outside and negative inside. This difference is called potential difference. The potential difference across the plasma membrane is known as resting potential. This potential averages - 70 mv (- 40 to - 90 mv) in inner side of membrane in respect to outer side.

A higher concentration of cations outside the membrane compared to the concentration of cations inside it. This state of the resting membrane is called polarised state and makes its inner side electronegative to its outside.

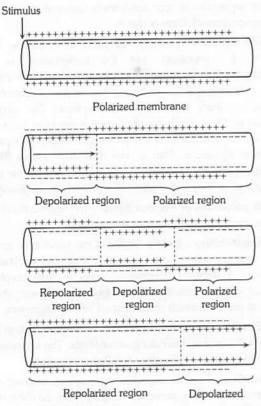

Fig: 5.6-20 Transmission of nerve impulse

(ii) Depolarization (Action membrane potential or AMP): When the nerve fibre is stimulated mechanically, electrically, thermally or chemically a disturbance is felt at the point of stimulation which gives rise to a local excitatory state. The membrane becomes permeable to sodium ions. The membrane is negatively charged on the outside and positively charged on the inside. The membrane with reversed polarity is said to be depolarized. This wave of depolarization travelling down a nerve fibre is called action potential. Infact, the action potential "moves" in the manner of a spark moving along a fuse. This "moving" action potential constitutes the nerve impulse. The action potential (impulse) is the basic means of communication within the nervous system. The action potential of + 45 mv on inner side of axolemma in respect to its outer side is also called spike potential.

(iii) **Repolarization**: With the increase of sodium ions inside the nerve cell, the membrane becomes less permeable to sodium ions whereas the permeability of the membrane to potassium ions increases. The sodium ions are pumped out of the cell and potassium ions are pumped into the cell until the original resting state of ionic concentration is achieved. Thus this makes the membrane negative on inside and positive on outside. This process is called repolarization.

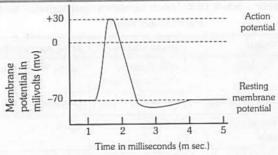

Fig: 5.6-21 Record of potential changes

The last movement of ions is thought to take place by an active transport mechanism called sodium potassium pump (also called sodium potassium exchange pump or sodium pump). The sodium-potassium pump is a process of expelling out sodium ions and drawing in potassium ions against concentration and electrochemical gradient. The entire process of repolarization requires some time during which the nerve cannot be stimulated again. This period is called **refractory period**. During repolarization, as the cell returns to its resting potential, the neuron is ready to receive another stimulus.

The synapse: The synapse is an area of functional contact between one neuron and another for the purpose of transferring information. Synapses are usually found between the fine terminal branches of the axon of one neuron and the dendrites or cell body of another. This type of neuron is called axo-dendrite synapse. Sir Charles Sherrington (1861-1954) was the first person who used the term 'synapse' to the junctional points between two neurons.

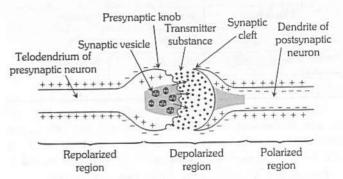

Fig: 5.6-22 Impulse conduction at synapse

(1) Structure of synapse: A typical (generalized) synapse consists of a bulbous expansion of a nerve terminal called a presynaptic knob lying close to the membrane of a dendrite. The cytoplasm of the synaptic knob contains mitochondria, smooth endoplasmic reticulum, microfilaments and numerous synaptic vesicles. Each vesicle contains neurotransmitter (chemical substance) responsible for the transmission of the nerve impulse across the synapse. The membrane of the synaptic knob nearest the synapse is thickened and forms the presynaptic membrane. The membrane of the dendrite is also thickened and is called the post synaptic membrane. These membranes are separated by a gap, the synaptic cleft. It is about 200 Å across The post synaptic membrane contains large protein molecules which act as receptor sites for neurotransmitter and numerous channels and pores.

UNIVERSAL BOOK DEPOT 1960

The two main neurotransmitters in vertebrate nervous system are acetylcholine (ACh) and noradrenaline although other neurotransmitters also exist. Acetylcholine (ACh) was the first neurotransmitter to be isolated and obtained by Otto Loewi in 1920 from the endings of parasympathetic neurons of the vagus nerve in frog heart. Neurons releasing acetylcholine are described as cholinergic neurons and those releasing noradrenaline are described as adrenergic neurons.

- (2) Mechanism of transmission of nerve impulse at a synapse: The process of chemical transmission across synapses was discovered by Henry Dale (1936). The physiological importance of synapse for the transmission of nerve impulses was established by McLennan in 1963. A brief description of the mechanism of synaptic transmission is given below
- (i) When an impulse arrives at a presynaptic knob, calcium ions from the synaptic cleft enter the cytoplasm of the presynaptic knob.
- (ii) The calcium ions cause the movement of the synaptic vesicles to the surface of the knob. The synaptic vesicles are fused with the presynaptic membrane and get ruptured (exocytosis) to discharge their contents (neurotransmitter) into the synaptic cleft.
- (iii) The synaptic vesicles then return to the cytoplasm of the synaptic knob where they are refilled with neurotransmitter.
- (iv) The neurotransmitter of the synaptic cleft binds with protein receptor molecules on the post synaptic membrane. This binding action changes the membrane potential of the postsynaptic membrane, opening channels in the membrane and allowing sodium ions to enter the cell. This causes the depolarization and generation of action potential in the post-synaptic membrane. Thus the impulse is transferred to the next neuron.
- (v) Having produced a change in the permeability of the postsynaptic membrane the neurotransmitter is immediately lost from the synaptic cleft. In the case of cholinergic synapses, acetylcholine (ACh) is hydrolysed by an enzyme acetylcholinesterase (AChE) which is present in high concentration at the synapse.
- (vi) The products of the hydrolysis are acetate and choline which are reabsorbed into the synaptic knob where they are resynthesized into acetylcholine, using energy from ATP.

Table: 5.6-5 Types and Nature of Neurotransmitters

S.No.	Excitatory	Inhibitory
1.	Acetylcholine	Gamma amino butyrio acid (GABA)
2.	Norepinephrine (NE)	Glycine
3.	Serotonin	
4.	5-hydroxy tryptamine (5-HT)	
5.	Dopamine	
6.	Histamine	
7.	Glutamate	
8.	Epinephrin	THE BUDGE AND THE
9.	Gastrin	
10.	Glucagon	The security of the Salah
11.	Melatonin	
12.	ADH	

(3) **Neurotransmitters**: As explained in the discussion of synapses, neurotransmitters are chemicals released from a presynaptic neuron that interact with specific receptor sites of a postsynaptic neuron. At least sixty chemicals thought to have the capacity to act as neurotransmitters have been discovered.

Synapse, A one-way valve: The synapse cannot transmit an impulse in the reverse direction as the dendrites cannot secrete a neurotransmitter. Thus, the synapse acts as a one-way valve, allowing the conduct of impulse from axon to dendron only.

Synaptic delay: Transmission of an impulse across a synapse is slower than its conduction along a neuron. This is because of the time needed for the release of a neurotransmitter, its diffusion through the synaptic cleft, and its action on the postsynaptic membrane. The difference in the rate is called synaptic delay. It amounts to about half a millisecond at body temperature (37°C).

Synaptic fatigue: It is a temporary suspension of impulse transmission in the region of synapse due to exhaustion of its neurotransmitter. It lasts for several seconds during which the neurotransmitter is resynthesized. Synaptic fatigue is the only fatigue that affects the nervous tissue. Conduction of the nerve impulse along the neurons is not subject to fatigue.

"All or None law" (Keith Lucas, 1905): When stimulated, the axon membrane (= axolemma) does not respond for a moment due to its resistance or threshold to stimulation. However, when its threshold is broken, the stimulation is conducted through its whole length as a strong impulse. If the stimulation is too weak to break the axon's threshold, impulse is not established, but if the intensity of stimulation is much more than the threshold value, impulse conduction remains normal. Thus, the action potential obeys "all or none law". In other words, impulse conduction is such a triggered phenomenon which, though occurs in a twinkling, like an explosion, but only when it reaches "ignition point" or firing level".

Sense Organs

How are environmental changes detected? In its broadest context, sensation is the conscious or unconscious awareness of external or internal stimuli. Cells which are specialised to receive stimulation are called receptors.

The sensory system consists of simple to complex structures called sensory receptors. An animal responds to a stimulus in a four-step process – sensory transduction, transmission, integration and response.

Types of receptors

- Exteroreceptors: Receive stimulation directly from external environment. These may be of following type
 - (i) Photoreceptor: Sensitive to light (Eye)
 - (ii) Thigmoreceptor: Sensitive to touch.
 - (iii) Tectoreceptor: Sensitive to touch.
 - (iv) Tangoreceptor: Sensitive to touch pressure.
 - (v) Phonoreceptor: Sensitive to sound (Ear).

- (vi) Olfactoreceptor: Sensitive for smell (Nose).
- (vii) Gustoreceptor: Sensitive to taste (Tongue).
- (viii) Thermoreceptor: Sensitive to temperature.
- (ix) Calo receptor: Sensitive to heat.
- (x) Frigido receptor: Sensitive to cold.
- (xi) Galvano receptor: Sensitive to electric current.
- (xii) Rheoreceptor: Sensitive to water or air current.
- (xiii) Geo receptor: Sensitive to gravity.
- (xiv) Telereceptor: Sensitive to distance. (Receptors of vision, hearing and smell receive stimuli from a distance hence called telereceptor).
- (2) Proprioceptors: Proprioceptors are located in skeletal muscles, joints, tendons etc. It is from these receptors that we know the position of our arm or leg without having to look at it.
- (3) **Intero receptor :** These are present in internal organ. Ex. receptor for hunger, thirst, pain and balancing.

Few important receptors

- (1) Important tangoreceptor
- (i) Merckel's corpuscles: Found in epidermis (stratum malpighi) of skin.
- (ii) Merckel's disk: Found in epidermis (stratum malpighi) of skin.
- (iii) Meissner's corpuscles: Present in skin around the base of hair and feather. These are sensitive for touch and pressure both
- (iv) **Genital corpuscles**: These are sensitive cells with nerve endings in skin around the genital organ.
- (v) **Grandey's corpuscles**: Found in birds at the base of the beak. These are kidney shaped in structure.
 - (vi) Herbert corpuscles: Found in buccal cavity of birds.
- (vii) Capsulated corpuscles: These are sensitive cells encapsulated and found in skin.
- (viii) Pacinian corpuscles: Found in deep layer of dermis and sensitive to pressure.
- (ix) Golgi corpuscles and Mazzoni corpuscles: These are sensitive to touch and found in subcutaneous region.
 - (2) Important Olfactoreceptor

Jacobson's organ (Vomero-nasal organ): It is concerned with smell. These were 1st appear in amphibians and well developed in snake, lizzard and sphenodon that is reptile. These are less developed in birds and mammal. Structure is blind sac like and lined by olfactory epithelium (Shneiderian membrane). Jacobsons organ is not found in rabbit. In man it is vestigeal organ. In human foetus Jacobson organ present. Jacobson organ also found in marsupiales, Rodents, and Insectivora.

- (3) Important Thermoreceptor
- (i) Krause end bulb: These are sensitive for temperature and pain and frigido in nature. Found in lips, tongue, conjunctiva of eyes and corium of finger.
- (ii) Organ of Ruffini: Sensitive to temperature and mainly related with heat.
- (iii) Ampulla of Lorenzini : Found in snout region of cartilagenous fishes these are helpful in detecting the temperature of water.

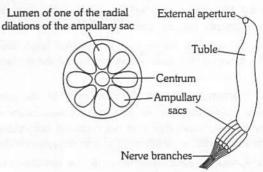

Fig: 5.6-23 Ampulla of Lorenzini

Eye

Human have binocular vision. The eye can discriminate colour, appraise length, width and depth visually and form true inverted image.

Structure of eye

The eyes are two in number and lodged in orbits (bony socket) of skull. The eye is a hollow, spherical organ, about 2.5 cm in diameter and about 6 to 8 gram in weight. It has two parts –

- (1) Protective devices: Eye has four protective devices.
- (i) Eye brows: The outwardly directed hair of the eyebrows carry the sweat and rain drops trickling down the forehead to the sides to prevent their falling into the eyes.
- (ii) Eye lids (Palpebrae): In man two eyelids are present, upper is movable. They are regularly closed at short intervals to clean the cornea. This is called blinking. In frog out of two upper eyelid is immovable and lower eyelid is movable. Nictitating membrane is present in frog which protect eye in water. Movement of nictitating membrane takes place by retractor bulbi. It becomes folded by levator bulbi.

A nonfunctional vestigeal nictitating membrane, called plica semilunaris, occurs in human eyes. It remains permanently retracted at the inner angle of each eye.

(iii) Eye lashes: The eyelids bear at the free edge a row of stiff hair, the eye lashes. These check the entry of dust particles, tiny insects and rain drops into the eyes.

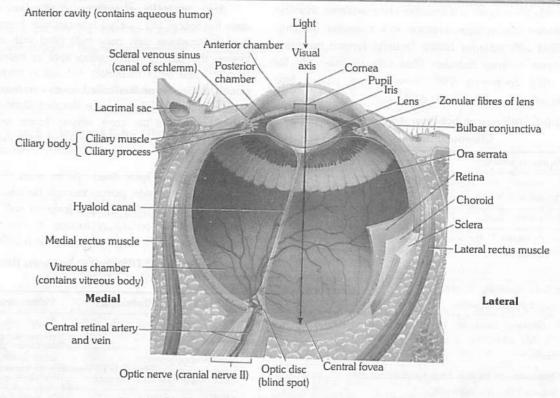

Fig: 5.6-24 Superior view of transverse section of right eyeball

- (iv) Eye glands
- (a) Meibomian gland: The eye-lids bear at the free edge a row of meibomian gland that is modified sebaceous gland. (Act as a lubricant).
- (b) Lacrimal gland or Tear gland: It lies in the upper outer part of the orbit and secretes a slightly saline, watery fluid that contains a bacteriolytic enzyme named lysozyme. This secretion moistens the surface of the eyeball. The excess of this secretion passes through nasolacrimal duct. It is modified sweat gland.
- (c) Harderian gland : Some aquatic mammals (whale) possess harderian gland which lubricate nictitating membrane. It is also found in frog and birds.
- (d) Glands of zeis (zis): These are modified sebaceous gland, found at base of hair follicle of eye lashes, pour lubricating fluid in hair follicle. Infection of these glands is Sty.
- (e) Glands of Moll: It is modified sweat gland and open into the follicles of eyelashes.

In human meibomian, lacrimal, Moll's glands, and zeis glands are present.

- (v) Connective tissue: A layer of fatty connective tissue surrounds the eyeball. It serves as a soft shockproof pad.
 - (2) Eyeball: Eyeball is made up of 3 coats or tunic.
- (i) Sclerotic layer (Fibrous tunica): Outer most and opaque, fibrous and non-vascular layer easily seen as white of the eye. It is a coat of dense connective tissue made up of collagen fibres and fibroblasts. Sclera covers entire eyeball except cornea, gives shape to eyeball. Sclera in frog is cartilaginous.

- (a) **Cornea**: In the centre, sclerotic layer it merges with the transparent round window called cornea.
- (b) Conjunctiva: The cornea and exposed part of sclera are covered externally by a thin, transparent membrane the conjunctiva.
- (ii) **Choroid layer (Vascular tunica):** Also known as uvea middle. It is vascular layer which supplies nutrients to the eye. It is distinguished into three parts choroid, ciliary body and iris.
- (a) Choroid: It is highly vascular posterior portion of vascular tunic. The choroid occurs in the main part of eyeball adhered to the sclerotic. (The pigment is reddish in rabbit and black, brown or bluish in man).
- (b) Ciliary body: Ciliary body is vascular and pigmented like choroid, made up of ciliary processes and ciliary muscles (only circular type). The ciliary body is hidden by iris. The ciliary body helps in accommodation by altering the focus of eye from object or the shape of lens near or far vision.
- (c) **Iris**: Beyond the ciliary body, the vascular tunic sharply turns inwards, forming a circular, shelf-like diaphragm called iris. The colour of the iris is responsible for colour of eye e.g., brown, black, blue or green. In albinos, iris is deficient of pigments.

Lens: Lens is colourless, transparent and fibrous crystalline structure made up of protein (α and β crystalline protein) and enclosed in lens membrane. It is ectodermal in origin. Lens is lodged in eyeball by suspensory ligament of ciliary body. Suspensory ligaments are known as "Zonula of Zinn". In man lens is biconvex while in frog it is elliptical (subspherical).

Lens divide the eyeball in 2 chamber outer aqueous chamber (partially divided into a large anterior and a smaller posterior chamber) filled with aqueous humor (watery) formed by ciliary body and inner vitreous chamber filled with vitreous jelly (or Wharton's jelly) containing 99% water, some salt a little mucoprotein (vitrein) and hyaluronic acid.

Table : 5.6-6 Differences between Aqueous humour and Vitreous humour

S.No.	Aqueous humour	Vitreous humour
1.	It occurs in aqueous chambers.	It occurs in vitreous chamber.
2.	It is a watery fluid	It is a jelly-like substance.
3.	It is secreted by ciliary processes.	It is apparently secreted by retina during development of eye.
4.	It is continuously absorbed into blood and replaced.	It is not absorbed or replaced
5.	It contains most of the diffusible substances of the plasma	It consists of water (99%) protein vitrein, hyaluronic acid and collagen fibres.
6.	Obstruction in its flow may damage retina by increasing intraocular pressure.	It does not flow.
7.	Refractive index is 1.33 D	1.34 D

- (iii) Retina (Neurosensory tunica): It is innermost, thin and transparent, purplish red due to the presence of the eye pigment rhodopsin (in rods) or visual purple which was extracted by Kuhne (1876) and named 'Schpurpur' (Visual purple). Made up of 4 distinct layer
 - (a) Cuboidal pigmented epithelium (towards choroid).
 - (b) Layer of rods and cones.
 - (c) Layer of bipolar neurons.
 - (d) Layer of ganglia (Towards vitreous chamber innermost).

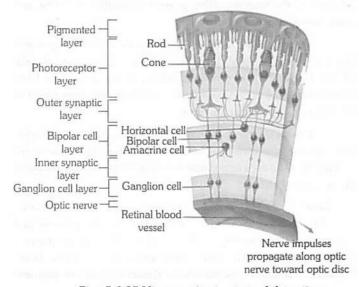

Fig: 5.6-25 Microscopic structure of the retina

Area centralis of retina: A little part of retina that lies upon the optical axis is called area centralis. Here, the retina is very thin and contains only cone cells filled with a yellow pigment. Hence, this part is called yellow spot or macula lutea. In man (Rabbits) and other mammals, but not in frogs, this area has a small shallow depression called fovea centralis. The later is the most sensitive part of an eye, i.e. the area of most acute vision. It is also claimed that the cone cells in fovea centralis are placed somewhat obliquely. So that these can form magnified images of object.

Blind spot (Optic disc): At this point, the optic nerve turns towards the outer side, pierces through the whole thickness of the wall of eyeball, forming an optic foramen and runs to the brain. Obviously, the region of optic foramen has no retina. It therefore, does not take part in image formation and is called blind spot.

Table: 5.6-7 Differences between Blind spot and Yellow spot

Blind spot (Optic disc)	Yellow spot (Macula lutea)	
It lies a little away from the yellow spot.	It lies exactly opposite the centre of the cornea.	
It contains no pigment.	It has a yellow pigment.	
Optic nerve starts from this spot.	No nerve starts from this spot.	
It lacks a depression.	It has a shallow depression, the fovea centralis, at its middle.	
It lacks visual receptors and is insensitive to light.	It has visual receptors and is sensitive to light.	
The eye coats are absent at blind spot.	Eye coats are present at yellow spot.	
No image is formed at this place.	Image is formed at this place.	

Ora seratta : The functional retina terminates anteriorly along an irregular border, the ora seratta.

Table: 5.6-8 Function of the parts of human eye

Part	Function	Part	Function
Lens	Refracts and focuses light.	Ciliary body	Holds lens in place.
Iris	Regulates light entrance.	Retina	Contains receptors.
Pupil	Admits light.	Rods	Allow black and white vision
Choroid	Absorbs extra light.	Cones	Allow colour vision
Sclera	Protects	Optic nerve	Transmits impulse.
Cornea	Refracts light.	Fovea centralis	Region of cones in retina
Humours	Refracts light.		

Working of eye

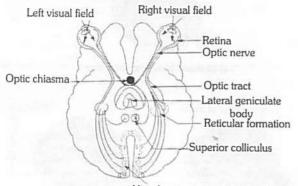

(i) Mechanism of light perception: The human eye
has two functional parts - Dioptric or Focussing part and
Receptor part.

UNIVERSAL BOOK DEPOT 1960

- (ii) Focussing part: It consists of conjunctiva, cornea, aqueous humour, lens and vitreous humour. These part are transparent and act as lenses. They refract the light rays passing through the eye to bring them to a focus on the retina. Maximum refraction is caused by the cornea, which places the image approximately on the retina. The lens effects fine adjustment and brings the image into a sharp focus.
- (iii) Receptor part: It comprises the retina. The image formed on the retina is inverted and smaller. It converts the energy of specific wave lengths of light into action potential in nerve fibre.
- (a) Pathway of sensory impulses from eye to brain: The nerve impulses generated in the retina of the eye in response to light follow a definitive path and terminates in visual cortex in each optic lobe which act as primary visual center.

Biochemistry of eye

The receptor cells of eye are called photoreceptor or visual cells. They are of two types – Rod cells and Cone

Visual cortex in occipital lobes (integrated interpretation action; memory)

Fig: 5.6-26 Pathway of sensory impulses from eye to brain

- (1) Rod cells: The rod cells contain a purplish pigment called visual purple or rhodopsin. They function in dim light and at night. They produce poorly defined images. Bright light splits rhodopsin into a lipoprotein scotopsin and a carotenoid pigment retinal (retinine) a process called bleaching. The splitting of rhodopsin depolarizes the rod cell and it releases a neurotransmitter, passing the nerve impulse via bipolar neuron and ganglion cells to the optic nerve. In the dark, rhodopsin is resynthesized from scotopsin and retinal. This process is called 'dark adaptation'. It makes the rods functional. It takes sometime for rhodopsin to be reformed. This is why on entering a dark room at daytime or on coming out of a well lighted room at night we feel blind for a while, when we go from darkness into bright light, we feel difficulty in seeing properly for a moment till rhodopsin is bleached and cones become functional.
- (2) Cone cells: Cones contain iodopsin which is visual violet and made up of photopsin + retinal. The 3 types of cones are erythrolabe (775 nm sensitive to red), cyanolabe (430 nm sensitive to blue) and chlorolabe (sensitive to green 535 nm). However, if all the cone, types are simultaneously stimulated by equal amounts of coloured light than sensation for white light is perceived.

Diurnal animals are adapted to see during day light (Photopic vision) and can perceive colour. In dark, colours are not perceived. Such animals have more cones in their eye than rods.

Table : 5.6-9 Differences between Rod cells and Cone cells

Rod cells	Cone cells
Rods secreted by rod cells.	Cones secreted by cone cells
Produce "Rhodopsin" which is visual purple and made up of scotopsin+11 cis retinal.	Produce "lodopsin" which is visual violet and made up of photopsin+11 cis retinal.
Vitamin-A is needed for the formation of Rhodopsin.	
Rhodopsin is very sensitive to light.	It is sensitive to colour.
Rods are active in dim light or low intensity light.	Cones are active in bright light which is called photopic vision.
Rod cells are absent in fovea centralis of retina.	In fovea centralis only cone cells are present.
Rods are more in number in peripheral region of retina.	Cones are more in number in central region of retina.
Rods are more in nocturnal animals.	Cones are more in diurnal animals.
In owl only rods are present and cones are absent.	In fowls only cones are present and rods are absent.
120 million rods in human.	6 million cones in human.

Accommodation and types of vision

(1) Accommodation: Light passes through many refractive surfaces before it is focussed on the retina forming an inverted and true image. The main sites of refraction are cornea → aqueous humor − iris − lens (position can be altered by ciliary body: accommodation) − posterior chamber (= vitreous humor) → retina (in fovea). The refractive index of the eye varies from 59 diopter (when the lens is at rest) to about 71 diopter (when lens is bulging in maximum accommodation). The accommodation reflex occurs when the eye changes its focus from a far away object to nearer one. The change in strength of the lens provides the physiological basis of accommodation. Radial and circular muscle fibres of ciliary muscles play an important role in this as they contract reflexively (parasympathetic control) and increase lens strength. The pupil constricts. This facilitates increase in sharpness of image. Ageing causes loss of accommodation.

Table: 5.6-10 Relationship between structures during

Object	Ciliary muscle	Suspensory ligament	Lens	Refraction
Near	Contracted	No tension (Relaxed)	Thick	Increased
Distant	Relaxed	Tension maximum	Thin	Decreased

(2) Types of vision

- (i) Binocular vision: Man has binocular vision in which both the eyes are focussed on the same object but from slightly different angles. The visual fields of both eyes overlap and the foveae of both are focused on the same object. This provides depth to the images, i.e., gives stereoscopic or 3D effect and enables man to judge distances correctly.
- (ii) **Vision in other animals :** Primates and predatory animals, such as owl and cat, have binocular vision. In some animals, such as rabbit, birds, each eye is focussed on a separate object. This is termed monocular vision.
- (iii) **Colour vision**: It is the ability of some animals to detect colours in an object. Humans, apes, monkeys, and most fishes, amphibians, reptiles and birds have strong colour vision. The insects and crayfish also have colour vision. In vertebrates, colour vision results from the activity of cone cells. Most domestic and nocturnal mammals and sharks lack colour vision. They probably see objects in shades of grey (monochrome vision).
- (iv) **Nocturnal and Diurnal vision**: Man has both day vision and night vision as he has both rods and cones in considerable numbers in the retina. Most birds have only day vision as their retina contains mainly cones. Owls have much better night vision than day vision for they possess a large number of rods and few cones in their retina.

Range of vision: The visible range of spectrum varies in animals. Bees, ants, spiders and goldfish can see ultraviolet light, which is invisible to man.

Table: 5.6-11 Correspondence between Camera and Eye

S.No.	Camera	Eye	
1.	Box	Sclera	
2.	Black inner paint	Choroid	
3.	Shutter	Eyelids	
4.	Diaphragm	Iris	
5.	Light hole	Pupil	
6.	Lens	Lens	
7.	Light-sensitive plate or film	Retina	
8.	Image small and inverted	Image small and inverted	

Eye movement

In eye orbit eyeball remain attached with 6 extrinsic muscles.

Out of six, first four are rectus and last two are oblique muscles.

- (1) Anterior rectus or Internal rectus
- (2) Posterior rectus or External rectus
- (3) Inferior rectus
- (4) Superior rectus
- (5) Inferior oblique muscle
- (6) Superior oblique muscle

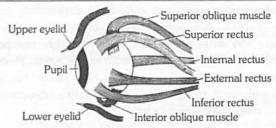

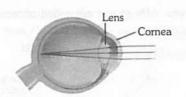

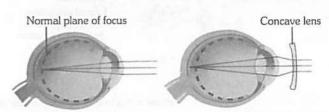

Fig: 5.6-27 Extrinsic muscles of eyeball

Eye defects

- (1) Myopia (Short or Near-sightedness)
- (i) Near object is clear. Far object is not clear.
- (ii) Eyeball become longer.
- (iii) Image is formed before retina. Can be removed by concave lens.

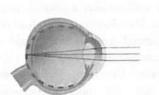

(a) Normal (emmetropic) eye

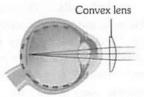

(b) Nearsighted (myopic) eye, uncorrected

(c) Nearsighted (myopic) eye, corrected

(d) Farsighted (hypermetropic) eye, uncorrected

(e) Farsighted (hypermetropic) eye, corrected

Fig: 5.6-28 Diagrammatic representation of eye defects

- (2) Hypermetropia (Long or Far sightedness)
- (i) Far object is clear, near object is not clear.
- (ii) Eyeball become short.
- (iii) Image is formed behind the retina.
- (iv) Can be removed by convex lens.
- (3) Astigmatism
- (i) Curvature of cornea become irregular and image is not clearly form.
 - (ii) Can be removed by cylindrical lens.

UNIVERSAL BOOK DEPOT 1960

(4) Cataract

- (i) It is due to defective protein metabolism.
- (ii) During this lens or cornea sometime both become opaque.
- (iii) Operation is needed.

(5) Glaucoma

- (i) It is due to increase in intraocular pressure in aqueous chamber.
- (ii) Operation is needed at early stage due to blockage of schlemm's canal.

(6) Trachoma

- (i) It is increased in redness of eye and more secretion of watery fluid.
 - (ii) It is due to infection of bacteria, chlamydia trachomatis.
 - (iii) Due to this follicles may form in conjunctiva.

(7) Xerophthalmia

- (i) It is due to deficiency of vitamin A. (A2)
- (ii) During this conjunctiva or cornea becomes keratinized.
- (iii) It may lead to blindness.

(8) Strabismus

- (i) In this type eyeball remain in some what in bended position.
- (ii) It is due to long extra ocular muscles during development of eye.
 - (iii) Operation is needed at early stage.
 - (iv) Also associated with squint.

(9) Presbyopia

- (i) During this power of accommodation of lens decreases due to age factor and defected metabolism.
 - (ii) Also known as age sightness.
 - (iii) Can be removed by bifocal lens.
 - (10) Photophobia: No clear image in bright light.
 - (11) Emmetropia: Normal vision.

Phonoreceptor and Mechanism of hearing or auditory sensations and equilibrium

Also known as stato-acoustic organ. It is the receptor for balancing and hearing which is sensitive for gravity and sound waves. It is also sensitive in orientation of body. It is also known as mechano receptor because of it change mechanical energy of sound waves into action potential.

Structure of Ear

Ear of mammal is divided into 3 parts -

(1) External ear: It is made up of pinna and auditory meatus. Pinna is found in only mammals. Its upper rounded part is

helix and lower is ear lobe. It is made up of adipose connective tissue and elastic cartilage and has ear muscles which are vestigeal in case of human beings. Pinna collect the sound waves and drive towards auditory meatus.

Auditory meatus is 25 mm. long canal lined by simple columnar epithelia and made up of fibro elastic cartilage. It possesses ceruminous gland which secrete cerumin (ear wax). Cerumin trap the dust particles and microbes.

Tympanic membrane: It is also called ear drum and present at the junction of auditory meatus and tympanic cavity.

(2) Middle ear: The cavity of middle ear is known as tympanic cavity which is enclosed by tympanic bulla bone of skull and filled with air. Middle ear separated from external ear by ear drum and from internal ear by thin bony portion or partition with two openings known as oval and round window.

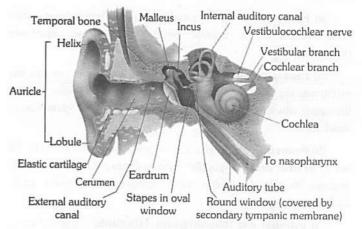

Fig: 5.6-29 Right internal ear

(i) Ear ossicle: A chain of three small, movable bones, the auditory or ear ossicles crosses the tympanic cavity. The outer ossicle is attached to the inner surface of the tympanic membrane.

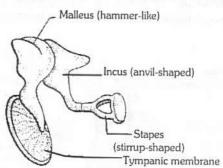

Fig: 5.6-30 Ear ossicles

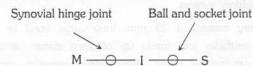

Table: 5.6-12 Ear ossicles

Ear ossicle	Shape	Modification of
M – Malleus	Hammer shaped	Articular bone of lower jaw.
I – Incus	Anvil shaped	Quadrate bone
S – Stapes	Stirrup shaped	Hyomandibular of columella

In man ear ossicles are known as H.A.S. stapes is the smallest bone of the body. In frog only stapes is present.

(ii) Joints

(iii) Muscles

Tensor tympani: Limits movements and increases tension on eardrum to prevent damage to inner ear from loud sound.

- (iv) Eustachian tube: It is made up of elastic cartilage and it connects middle ear to nasopharynx. It maintain equilibrium in and out side of the tympanic membrane. Blocking of eustachian tube impairs hearing due to imperfect vibrations of drum. Eustachian tube is normally closed, it opens during swallowing and yawning.
- (v) **Fenestrae**: Between middle ear and internal ear a thin bony membrane is present which possess two apertures (Windows).
- (a) Fenestra ovalis: It is upper window, connect middle ear to internal ear and guarded by membrane. End of stapes is fit on the upper window. It is towards vestibule so it is also known as F. vestibuli.
- (b) **Fenestra rotundus**: It is ventral window, connect middle ear to internal ear and guarded by membrane. It is towards scala tympani so it is also known as *F. Tympani* (also known as *F. cochleae*).
- (3) Internal ear (Membranous labyrinth): Internal ear is also known as membranous labyrinth and enclosed by bony labyrinth. Bony labyrinth is formed by periotic bone or petrous. A cavity is present between membranous labyrinth and bony labyrinth known as perilymphatic space. It is filled with perilymph and endolymph is found in membranous labyrinth. The membranous labyrinth consists of 2 parts Vestibule and Cochlea.

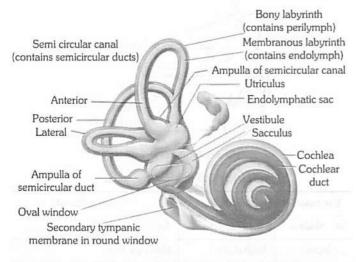

Fig: 5.6-31 Section through the cochlea (Semicircular canals, vestibule and cochlea of the right ear

- (i) **Vestibule**: The vestibule is a central sac like part. It further consists of 2 chambers large Utriculus (Upper) and smaller sacculus (lower).
- (a) **Semicircular canal :** From utriculus 3 semicircular canals arise these are –

Anterior semicircular canal (Superior)

Posterior semicircular canal (Inferior)

Horizontal semicircular canal (External)

They are perpendicular each other.

Crus commune : A common part of anterior and posterior semicircular canal arising from dorsal region of utriculus is known as crus commune.

Ampulla : Terminal part of the each semicircular canal is enlarged to form an ampulla.

Crista: Each ampulla has a sensory spot called crista ampullaris or simply crista, for equilibrium.

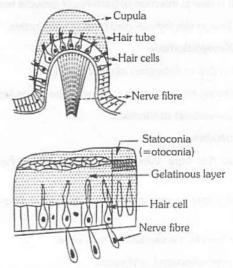

Fig: 5.6-32 Crista and macula of ear

(b) **Sacculus**: It is a lower chamber of vestibule. From the lower part of the sacculus arises a short tube, the ductus reuniens, that joins the cochlear duct.

Ductus endolymphaticus: It is filled with endolymph and arises from the junction of utriculus and sacculus.

Macula: are present in utriculus and sacculus. it is a group of sensory cells. In man (Rabbit) 2 maculas are present. (A crista resembles a macula in structure except that lies on an elevation, the acoustic ridge, its sensory cells have longer "hair", and its gelatinous mass is dome shaped, lacks otoliths and is called cupula.)

Table: 5.6-13 Difference between Crista and Macula

S.No.	Crista	Macula
1,	Found in ampulla of semi-circular canal	Found in vestibule i.e. sacculus and utriculus.
2.	Their total number is 3	Only 2 are present
3.	No otolith	Otolith present
4.	Long auditory hairs	Short auditory hair
5.	Facilitate maintenance of dynamic equilibrium and angular acceleration e.g. rotational movement of head	Help in static equilibrium and linear acceleration e.g. tilting of head or body at rest and rapid forward movement.

Otolith: Also known as otoconia made up of protein and calcium carbonate and present in endolymph.

- (ii) Cochlear duct and Cochlea: It is a spirally coiled tube (2-3 coiling) which is connected to sacculus by a short duct. It is divided into 3 chambers by 2 membranes.
- (a) Scala vestibuli: Upper chamber filled with perilymph
 connect with middle ear by F. ovalis, or oval window.
- (b) Scala media (Real cochlear duct): Middle chamber filled with endolymph.
- (c) **Scala tympani**: Lower chamber filled with perilymph connect with middle ear by *F. Tympani* or round window.
- (d) **Reissner's membrane**: Present at the roof of scala media, it saparate S.M. to S.V.

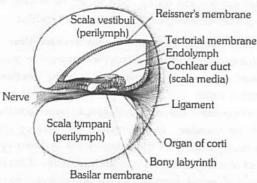

Fig: 5.6-33 Cochlear apparatus in T.S.

- (e) Basilar membrane: Present at the base of S.M. It is thicker than Reissner's membrane and it separates S.M. to S.T.
- (f) **Modiolus**: A bony core around which bony spiral canal of cochlea make $2\frac{3}{4}$ turns or coils in man.
- (g) Helicotrema: A aperture present in scala media which connect scala vestibuli to scala tympani is known as helicotrema.
- (h) Tectorial membrane: Tectorial membrane is a leaf like gelatinous structure present at the dorsal side of organ of corti.
- (i) **Organ of corti**: Discovered by Italian anatomist Alfanso-Corti. Also known as ridges of corti which are present in basilar membrane. Organ of Corti contains a variety of cells. They receives nutrients from endolymph. The cells of organ of Corti are following types –

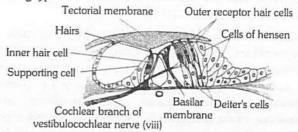

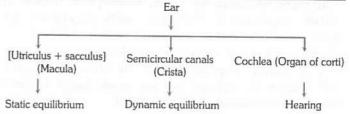

Fig: 5.6-34 Detailed structure of organ of corti (vertical section)

Table: 5.6-14 Characteristics of cells of organs of Corti

Receptor cell (=Hair cells)	Supporting cells	Tectorial membrane	Peripheral membrane
Two type (i)- inner hair cells – in one layer and number 3500, while the (ii) outer hair cells are in $3-4$ rows (20,000)	Support hair cells, These rest on basilar membrane	Flap of fibrous and gelatinous tissue, the outer right plate is called reticular lamina which is supported by rods or corti anchored to basilar membrane	Has restricted elasticity respond to low to high frequencies within audible region
Hair of outer hair cell extend into scala media and embeded in roof like tectorial membrane.	Provide nutrients and physical support to the hair cells		and companies.
Inner hair cells respond to the velocity of movement of the basilar membrane. While the outer hair cells are primarily concerned with the displacement of the basilar membrane by the sound waves.	They are not involved in sound transduction		
Hair cells have a basal body just under the hair. The basal body facilitates transduction of the mechanical signal to a neural signal (electrogenesis)			

Mechanism of sound perception

Vone Beskey won the Nobel prize for his work on ear. The mechanism found in ear involve two unrelated functions: Hearing and equilibrium.

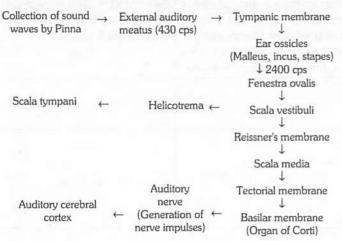

UNIVERSAL BOOK DEPOT 1960

970 Neural Control and Coordination

(1) Hearing: The ear not only detects sound but also notes its direction, judges its loudness and determines its pitch (frequency). Sound waves are collected by the pinna and directed inward through the external auditory meatus (frequency 430 cycle per second). Here they strike the tympanic membrane. The latter begins to vibrate at the same frequency as that of the sound waves. From the tympanic membrane, the vibration are transmitted across the tympanic cavity by the ear ossicles to the membrane of the fenestra ovalis. The force of vibrations is considerably increased in the middle ear by leverage of the ossicles and also by much smaller surface area of the membrane of fenestra ovalis than that of the tympanic membrane. (The frequency is 2400 cycle/sec). Increase in frequency is important because the sound wave are transmitted from air to a fluid medium. The membrane of fenestra ovalis transmits the vibrations to the perilymph of the scala vestibuli and hence via Reissner's membrane to the endolymph in the scala media. From here the vibrations are transferred to the basilar membrane and the perilymph in the scala tympani.

Vibration of the endolymph of the scala media cause the basilar membrane of this chamber vibrate. Vibrations of the basilar membrane make the "sensory hair" of receptor cells in the organ of corti move in the overlying gelatinous membrane (Tectorial membrane) and get distorted. This stimulation causes depolarisation of the receptor cells and initiation of nerve impulse in the fibres of the auditory nerve. The nerve impulse travels via relay centers e.g. spiral ganglion \rightarrow cochlear nuclei \rightarrow superior auditory nuclei \rightarrow inferior colliculi \rightarrow auditory cortex of cerebrum (The cerebral cortex interprets the impulses as sound). The various steps in the mechanism of hearing

Human ear can hear a frequency of 500 to 5000 hertz (Hz; 1 Hz = 1 cycle/second). However, it can hear the complete range of frequencies from 20-20,000~Hz only with intense sound. Sound energy is measured in terms of units called decibels (dB). Sounds in our city homes average 40-50~dB, but street noise averages 70-80~dB. Sounds upto 80~dB are considered bearable by man, but higher sound intensity are hazardous, causing nervous stress, irritability, increased blood pressure etc. Non stop noise of 90~or more dB produces temporary deafness. 160~dB sound can cause total deafness by rupturing our ear drum. Sound becomes uncomfortable to normal ear at about 120~dB.

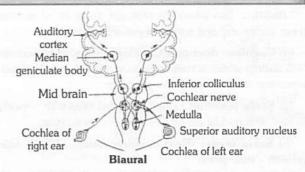

Fig: 5.6-35 Pathway of sound perception from organ of corti in cochlea to auditory cortex of cerebrum

- (2) **Equilibrium**: Sound become painful above 140 dB. Exposure to certain antibiotics, such as gentamycin some anticancer drugs, loud sound, loud music, or engine rear of jet planes, vacuum cleaners, damages hair cells of cochlea.
- (i) Static equilibrium and linear acceleration: Maculae detect changes in the head (or body) with respect to gravity (static equilibrium) and in the movement in one direction (linear acceleration). With a change in the position of the body, the otoliths, being heavier than the endolymph, press upon the sensory hairs of the maculae. This stimulates the sensory cells which initiates nerve impulse in the fibres of the auditory nerve. The macula of utricle responds to vertical movements of the head, and the macula of saccule responds to lateral (sideways) movement of the head.

On rapid forward movement, the otoliths, because of having greater inertia than the surrounding endolymph, lag behind and press back the sensory hair, stimulating the sensory cells to generate nerve impulses.

(ii) **Dynamic equilibrium**: Cristae detect turning or rotational movements of the head (angular acceleration). When the head is turned, the endolymph in the semicircular ducts, due to its inertia, does not move as fast as the head and the sensory cells of the crista, but continues to move after the head stops moving. Because of this difference in the rate of movement, the sensory hair of the cristae are swept through the endolymph and become bent over. This disturbance stimulates the sensory cells and sets up action potential in the fibres of the auditory nerve, which transmits it to the brain. Since the three semicircular ducts are arranged in three different planes, a movement of the head in any direction will stimulate the sensory cells of at least one crista.

Defects of ear

- Labyrinthine disease: Malfunction of inner ear.
- (2) **Meniere's disease**: Loss of hearing due to defect in cochlea.
 - (3) Otitis media: Acute infection of middle ear.
 - (4) Eustachitis: Inflammation of eustachian tube.
 - (5) Myringitis (Tympanitis): Inflammation of eardrum.
 - (6) Otalgia: Earache (pain in ear)

UNIVERSAL BOOK DEPOT 1960

Tips & Tricks

- Tela choroidea is the term used for epithalamus and piamater fused.
- Tela choroidea is made up of epithelium and blood vessels.
- Ataxia mean lacks of muscle coordination. Damage to cerebellum is characterized by ataxia.
- Dyslexia involves an inability of an individual to comprehend written language.
- Multiple sclerosis is the destruction of myelin sheath of neurons of CNS.
- An American scientist Roger Sperry got Nobel Prize in 1981 for his outstanding work on split brain theory.
- Parkinson's disease or Paralysis agitans is a defect of brain.
- Parkinsonism is characterised by tremors and progressive rigidity of limbs caused by a degeneration of brain neurons and a neurotransmitter called dopamine.
- Avian brain has large sized optic lobes to see the objects on the earth while flying so is called eye brain, while fish brain has large sized olfactory lobes to smell the prey from a distance so is called nose brain.
- In fishes: Cerebrum is not differentiated in two cerebral hemispheres.
- Hypothalamus has additional lobes to note pressure changes.
- In reptilian brain, pineal eye (parietal body) present in front of pineal body.
- Grey matter of spinal cord of frog is rectangular while it is butterfly-shaped in mammals.
- Central canal: Cavity of spinal cord.
- Optic bigemina: Two optic lobes in brain and are found from fishes to birds.
- Optic lobes of man are solid and have no optocoel but those of frog have optocoel.
- Optic tectum : Dorsal thick wall of optic lobe.
- Thalami of diencephalon act as relay centres as well as gate keepers of brain.
- Optic chiasma is meant for binocular vision.
- Olfactory lobes of human brain have no rhinocoel while those of frog have rhinocoel.
- Man and birds are less dependent upon smell so olfactory lobes are small sized but are large sized in cartilage fishes (dog fish), dogs and reptiles are more dependent upon smell.
- Cerebellum is large sized in fishes, birds and rabbit due to their multidirectional movements and increased dependency on balance.

- Stimulus for hunger: In February 1998, an American scientist Dr. Masashi Yanagisawa reported that a drop of sugar level in blood stimulates the appetite centres of lateral hypothalamus to release oraxin hormone (Gr. Oraxis = hunger) which stimulates hunger.
- Mervous disorders

Agnosia: Failure to recognize;

Alexia: Failure to read; Agraphia: Failure to write;

Aphasia : Failure to speak (due to injury to Broca's area)

Analgesia: Loss of sensation of pain;

Anesthesia: Loss of feeling; Insomnia: Inability to sleep;

Amnesia: Partial or complete loss of memory;

Coma: Complete loss of consciousness.

Aproxia: Inability to carry out purposeful movements.

Multiple sclerosis: Progressive degenerative disease of CNS and is characterized by many hard scar tissues.

- Brain stem : Diencephalon + mid brain + pons + medulla oblongata.
- Cerebro vascular accident (C.V.A) or stroke: Blocking of blood supply of a part of brain.
- Alzheimer: It is the disease appearing usually after 65 year. It is characterized by dementia usually. Usually in this disease ACh producing neurons of cerebral cortex and hippocampal lobe are degenerated. It is also seen that a amyloid protein is accumulated in the brain. It is the matter of research.
- Comissure: The band of nerve fibres between two similar ganglia.
- Associate fibres: If joining fibre are joining two similar structure in same halves then, they are called associate fibre.
- The rate of conduction in myelinated fibre of a mammal is very high because action potential jumps from node to node.
- The jumping of action potential from node to node (of Ranvier) in a fibre is called saltatory conduction.
- Nissl's or trigoid granules are present in the neuron and are made up of RNA, ribosome and RER. These granules help in excretion and nutrition.
- Intelligence quotient (I.Q.) is the ratio of mental age to chronological age multiplied by 100.
- Corpora striata, genu and splenium is found in cerebrum.
- Neurons stops dividing after birth.
- ✓ Optocoel is not found in mammalian brain.
- The pneumotaxic centre is found in pons.
- Transmission of nerve impulse can be recorded with the help of oscilloscope.
- Autonomous nervous system has paired chain ganglia.
- Paralysis of jaw muscles is due to loss of function of Vth cranial nerve.
- Bipolar nerve cell and ganglia cell are found in the retina.
- Arbor vitae are composed of white matter.

- A cavity in the ventricle of a brain is known as cerebral agua.

- The ganglia of sympathetic and central nervous system in frog develops from the neural crest cells.
- Cerebellum of post brain involved in loss of control when a person drinks alcohol.
- The maximum current required to stimulate a nerve is called rheobase or threshold current or firing level of impulse. It is about 15 my.
- Earthworm has both sensory and motor neurons.
- The glial cells that form the blood brain barrier by lining brain capillaries are the astrocytes.
- Axo-axentic is the condition when direction of nerve impulse is reversed.
- Unipolar nerve cells are found in vertebrates embryo.
- Saltatory conduction is found in all vertebrates.
- Corpus callosum is absent in the brain of prototherians and metatherians both.
- Degeneration or imperfect development of corpus callosum in human brain results in a neurological disorder called schizophrenia.
- γ-amino butyric acid is a neurotransmitter.
- Acetylcholine is the cardiac inhibitor.
- 5-Hydroxy tryptamine is a chemical transmitter.
- Spike phase of action potential is 2 m. sec.
- Sylvian fissure divides the brain of rabbit into frontal lobe and temporal lobe.
- Dorsal root has the ganglion made of pseudounipolar neurons.
- All cell bodies of afferent fibres lie in the dorsal root ganglion.
- EEG Electro-Encephalogram : Electrical tracing of the cerebral cortex is call EEG Berger in 1929 was first to record EEG. Instrument for the recording is Electroencephalograph or cathode ray oscilloscope.
- It is record of brain wave. Brain waves are of following type (i) α-wave: These are rhythmic waves (8-13 cycles per second. These are produced in normal awaking condition. These disappear in sleep.
 - (ii) β -wave ; 14-30 cycle per second. These are produced when nervous system is active e.g. Mental work.
 - (iii) θ-wave : 5-8 cycle per second. Produced in children.
 - (iv) δ -wave : 1-5 cycle per second. In normal condition these are produced in awake infants. These are produced in deep sleep. In damage condition of the brain waves may produce in awaking condition in adults.
- Fundamental character of chordates is the presence of dorsal hollow nerve chord.

- Somesthatic & taste area present in parietal lobe of cerebrum.
- Epilepsy: Is second common neurological disorder is characterized by short, recurrent, periodic attacks of motor, sensory, or psychological mal function. The attacks called epileptic seizures are initiated by abnormal, synchronus electrical discharge from millions of Neurons in brain. Due to this, a person undergoing an attack may contract skeletal muscles involuntarily, light, noise, smells may be sensed when eyes, ears, nose have not been stimulated. Epilepsy has causes, including brain damage at birth (Most common cause), hypoglycemia, hypocalcaemia, hypoxia, uremia, encephalitis, meningitis, and tumors.
- Nystagmus An uncontrolled oscillation of the eyes, is one of the symptoms of an inner-ear disease called Meniere's disease (from Prosper Meniere, French physician, 1799-1862).
- Cones are absent in nocturnal animals like shrews, hedge hogs, rodents and bats.
- ☑ During night the eyes of carnivores like cat, dog, lion, seal glow. It is due to tapetum lucidum a reflecting layer next to retina, which is made of crystaline layer with zinc, cysteine and guanine.
- Bees can see ultraviolet light.
- Deer has biggest eyes in proportion to body size.
- Except rabbit and man, harderian glands are found in whale, mice, shrews and in reptiles.
- Nocturnal animals have more rods than cones in their eye. The image formed has no colour but is black or grey, the edges are not sharp.
- ∠ Colour blindness It is known as daltonism. It is in between red and green colour. It is genetic defect.
- Colour vision is due to presence of specialise cone cell in Retina which value the sensitivity for different colours.
- Night blindness During this rhodopsin is not resynthesized or regenerate in dim light.
- Monocular vision found in frog, rabbit and horse.
- Binocular vision found in primates, ape, monkey.
- Colour vision found in fishes, reptiles, amphibia.
- Sty Sebaceous gland infection leading to its inflammation.
- There are only four basic modalities of taste, which are sensed most acutely in particular regions of the tongue. These are sweet (tip of the tongue), sour (sides of the tongue), bitter (back of the tongue) and salty (over most of the tongue.)
- Iris is the third portion of the vascular tunic.
- Atropine is a chemical used by doctors to dilate the pupil before testing.
- Photopic vision is associated with cones.
- Cornea grafting: Cornea can be removed from a dead man's eys, stored and grafted on another person's eye to restore vision, cornea transplantation is successful because it lacks blood vessels. Eye donation is a noble act.

INIVERSAL

Ordinary Thinking

Objective Questions

Development of central nervous system in human

1.	Which one of the	following	is	essential	for	the	formatio	n of
	myelin sheath				[(CBS	E PMT 19	990]

(a) Zinc

(b) Sodium

(c) Iron

(d) Phosphorus

2. Mammalian brain differs from an amphibian brain in [CPMT 1993; AFMC 1999; BHU 2008] possessing

(a) Olfactory lobe

(b) Hypothalamus

(c) Corpus callosum

(d) Cerebellum

Brain is [MP PMT 1994, 97, 2006; CPMT 1995, 98; RPMT 1995, 99, 2000, 06; Odisha JEE 2010]

(a) Ectodermal

(b) Mesodermal

(c) Endodermal

(d) Mesendodermal

Which cell stops dividing after birth

[MP PMT 1997]

Largest cell in body is

[CPMT 1992, 93]

(a) Neuron

(b) Glial

(c) Epithelium

(d) Liver

5. The second cranial nerve in human originates from

The second cranial nerve of frog is distributed in

(a) Ciliary muscles of eye

(b) Retina only

(c) Retina and lens

(d) Occular muscles of eye

The ganglia of sympathetic and the central nervous system in frog develops from the [AIIMS 2002]

(a) Neural cell

(b) Notochordal cells

(c) Neural plate cells

(d) Neural crest cells

7. Which is activated in stress condition

[DPMT 2003]

(a) Sympathetic

(b) Parasympathetic

(c) Somatic

(d) Whole ANS

8. The autonomic nervous system has control over

[Kerala CET 2003; MP PMT 2007]

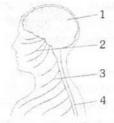

(a) Reflex action

(b) Skeletal muscles

(c) Sense organs

(d) Internal organs

The given diagram indicates part of the human body, the structures belonging to the central nervous system are numbered

(a) 3 and 4

(b) 1 and 4

(c) 2 and 3

(d) 1 and 3

Parts of nervous system

In man which one of the following cranial nerve is 1. associated with the sense of body balance [MP PMT 1992]

(a) VI

(b) VII

(c) VIII

(d) IX

2. How many pairs of sympathetic ganglia are present in ANS [MHCET 2015]

(a) 10

(b) 12

(c) 22

(d) 31

If a person has lost his memory in an accident, the following 3. part of the brain have got injured

[NCERT; CBSE PMT 1992; MP PMT 1994]

(a) Diencephalon

(b) Medulla oblongata

(c) Cerebellum

(d) Cerebrum

4. The hind brain consists of

[CBSE PMT 1992:

Kerala PMT 2009; CBSE PMT (Pre.) 2012]

(a) Pons + cerebellum

(b) Hypothalamus + cerebellum

(c) Medulla oblongata + cerebellum

(d) Medulla oblongata + cerebellum + pons

Which of the following regions of the brain is incorrectly 5. paired with its function [AIPMT (Cancelled) 2015]

(a) Cerebellum - Language comprehension

(b) Corpus callosum - communication between the left and right cerebral cortices

(c) Cerebrum - calculation and contemplation

(d) Medulla oblongata - homeostatic control

Which one of the following is responsible for the control of reflex action [AFMC 1999]

(a) Sensory nerves

(b) Motor nerves

(c) Sympathetic nervous system

(d) Central nervous system

The number of spinal nerves in man is

[KCET 1999; WB JEE 2012]

(a) 27 pairs

(b) 31 pairs

(c) 37 pairs

(d) 47 pairs

8 Which of the following cranial nerves are involved in the movement of eye [MH CET 2015]

(a) Optic, occulomotor, abducens

(b) Occulomotor, abducens, trochlear

(c) Trochlear, abducens and optic

(d) Abducens, optic, trochlear, occulomotor

9. The smallest cranial nerve in human being is

(a) Trochlear

(b) Opthalmic

(c) Abducens

(d) Vagus

Post-ganglionic nerve fibres of sympathetic system are 10.

[DPMT 2006]

[DPMT 2006]

(a) Adrenergic

(b) Cholinergic

(c) Both (a) and (b)

(d) None of these

The supporting and nutritive cells found in the brain are

Or

Ventricles of brain are lined by the cells called

[MP PMT 1997]

(a) Ependymal cells

(b) Microglia

(c) Astrocytes

(d) Oligodendrocytes

- Identify the origin of sympathetic nerve fibres and the location of their ganglia [CBSE PMT 1995; AIIMS 1998;
 BVP 2000; CPMT 2010; WB JEE 2012]
 - (a) They arise from thoraco-lumber region of spinal cord and form ganglia just beside the vertebral column
 - (b) They arise from thoraco-cervical region of spinal cord and form ganglia just beside the vertebral column
 - (c) They arise from cranio-sacral region of spinal cord and form ganglia very close to effector organ.
 - (d) They arise from thoraco-lumber region of spinal cord and form ganglia very close to effector organ
- Neural stimulation in visceral organ in human being is done by [CBSE PMT 1996]
 - (a) Sympathetic and parasympathetic nerves and is under involuntary action
 - (b) Sympathetic nerves and is under voluntary action
 - (c) Sympathetic and parasympathetic nerves and is under voluntary action
 - (d) Parasympathetic nerves and is under voluntary action
- 14. The third ventricle of the brain is situated in the

[AMU (Med.) 2010]

- (a) Base of telencephalon
- (b) Roof of metencephalon
- (c) Roof of diencephalon
- (d) Base of myelencephalon
- 15. The purely motor cranial nerve is

[Pb. PMT 2005]

- (a) Facial
- (b) Vagus
- (c) Trigeminal
- (d) Spinal accessory
- 16. Foramen of Monro is an aperture between [CBSE PMT 1992]
 - (a) 2nd and 3rd ventricle
- (b) Diocoel and metacoel
- (c) Rhinocoel and diocoel
- (d) 3rd and 4th ventricle
- 17. Hypothalamus of the brain is not involved in this function

[KCET 2012]

- (a) Sleep-wake cycle
- (b) Osmoregulation and thirst
- (c) Temperature control
- (d) Accuracy of muscular movement
- 18. Match List I with List II and select the correct option

	List I		List II
Α.	Sacral nerves	1.	1 pair
B.	Thoracic nerves	2.	8 pairs
C.	Coccygeal nerves	3.	7 pairs
D.	Cervical nerves	4.	12 pairs
E.	Lumbar nerves	5.	5 pairs

[Kerala PMT 2005, 08]

- (a) A-4, B-1, C-3, D-2, E-5
- (b) A-5, B-3, C-1, D-4, E-2
- (c) A-3, B-4, C-2, D-5, E-1
- (d) A-2, B-5, C-3, D-1, E-4
- (e) A-5, B-4, C-1, D-2, E-5

- In a myelinated neuron, two adjacent myelin sheaths are separated by gaps called [Kerala PMT 2008]
 - (a) Nodes of Ranvier
- (b) Synaptic cleft
- (c) Schwann cells
- (d) Synaptic knob
- (e) Neural plate
- 20. The branched tree like structure present in cerebellum is

Or

The tree of life is [DPMT 1993; Manipal 2005; BHU 2005]

- (a) Arbor vitae
- (b) Arboreal
- (c) Archenteron
- (d) Areole
- 21. The given figure is that of the human brain

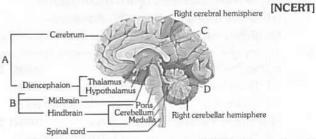

Identify the part that controls intelligence and memory is labelled [NCERT]

(a) IV

(b) III

(c) II

- (d) I
- Purely motor nerve is [BHU 1999, 2004; CPMT 2001, 02;
 MP PMT 2002, 06; MH CET 2003]
 - (a) Optic
- (b) Abducens
- (c) Opthalamic
- (d) Palatinus
- 23. See the following diagram and identify A, B, C and D

- (a) A Brainstem, B Forebrain, C Cerebral aqueduct, D Corpus callosum
- (b) A Brainstem, B Forebrain, C Corpus callosum, D -Cerebral aqueduct
- (c) A Forebrain, B Brainstem, C Cerebral aqueduct, D Corpus callosum
- (d) A Forebrain, B Brainstem, C Corpus callosum, D -Cerebral aqueduct
- 24. Pituicytes are under the control of
 - of [Odisha JEE 2012]
 - (a) Adenohypophysis(c) Neurohypophysis
- (b) Hypothalamus(d) Both (a) and (c)
- 25. Which one of the following statement is correct

[CBSE PMT 2006]

- (a) Neither hormones control neural activity nor the neurons control endocrine activity
- (b) Endocrine glands regulate neural activity, but not vice versa
- (c) Neurons regulate endocrine activity, but not vice versa
- (d) Endocrine glands regulate neural activity, and nervous system regulates endocrine glands

UNIVERSAL BOOK DEPOT 1960

26. The given diagram is the lateral view of the human brain, parts are indicated by alphabets. Select the answer in which these alphabets have been correctly paired with the parts which they indicate [NCERT]

A C C

- (a) A Frontal lobe, B Temporal lobe, C Cerebellum, D
 Medulla oblongata, E Parietal lobe
- (b) A Temporal lobe, B Parietal lobe, C Cerebrum, D
 Medulla oblongata, E Frontal lobe
- (c) A Frontal lobe, B Temporal lobe, C Cerebrum, D Medulla oblongata, E – Occipital lobe
- (d) A Temporal lobe, B Parietal lobe, C Cerebellum,
 D Medulla oblongata, E Frontal lobe
- 27. Parasympathetic ganglia are present in

[AFMC 2012]

- (a) Head and neck
- (b) Chains of lateral ganglia
- (c) Grey matter of thoracic and lumbar region of spinal cord
- (d) All of these
- 28. Consider the given diagram and identify "A"

[NCER

[BHU 2012]

- (a) Medulla oblongata
- (b) Cerebellum
- (c) Midbrain
- (d) Pons
- 29. Blood-brain barrier is formed by
- (a) Microglial cells
- (b) Astrocytes
- (c) Oligodendrocytes
- (d) Ependymal cells
- Which of the following cranial nerves innervates heart, stomach and lungs [CBSE PMT 1990;

MP PMT 1996; Odisha JEE 2009]

Or

Which of the cranial nerve is mixed

[WB JEE 2012]

- (a) Vagus
- (b) Accessory
- (c) Trigeminal
- (d) Trochlear
- 31. Parasympathetic nervous system increases the activity of

[DPMT 1992]

- (a) Gut, iris and urinary bladder
- (b) Heart, adrenal and sweat gland
- (c) Heart, pancreas and lacrimal gland
- (d) Lacrimal gland and sweat gland
- 32. The nervous strip connecting both the cerebral hemispheres in the rabbit is [NCERT; MP PMT 1994, 95; RPMT 1995; CPMT 1995; MH CET 2004, 06; WB JEE 2008;

Kerala PMT 2011]

- (a) Corpus callosum
- (b) Corpus albicans
- (c) Corpus stratum
- (d) Corpus spongiosum

33. The thermoregulatory centre is situated in

[AIIMS 1993, 2000; KCET 2000; CPMT 2001, 09; AFMC 2003]

Or

The control of blood sugar level, osmoregulation and thermoregulation are the function of [CBSE PMT 1993]

Or

The appetite and satiety centres in the brain of man are located in the region of the [CPMT 2009]

- (a) Spinal cord
- (b) Pituitary body
- (c) Cerebellum
- (d) Hypothalamus
- Nissl's granules are present in the and are made up of respectively [CBSE PMT 1997; BVP 2001; RPMT 2006]
 - (a) Muscle cells and deoxyribo nucleic acid
 - (b) Mast cells and RNA
 - (c) Osteocytes and DNA
 - (d) Neuron and RNA
- 35. During the course of evolution which part of the brain has shown maximum increase in size [Odisha JEE 2009]
 - (a) Mid brain
- (b) Fore brain
- (c) Hind brain
- (d) All of the above
- Skeletal muscles are controlled by
 - d by [DUMET 2009]
 (b) Parasympathetic nerves
 - (a) Sympathetic nerves(c) Somatic nerves
- (d) Autonomic nerves
- Select the answer with correct matching of the structure, its location and function [CBSE PMT (Mains) 2010: WB JEE 2016]

	Structure	Location	Function		
(a)	Eustachian tube	Anterior part of internal ear	Equalizes air pressure on either sides of tympanic membrane		
(b) (re		(b) Cerebellum Mid brain		Controls respiration and gastric secretions
(c)	Hypothalamus	Fore brain	Controls body temperature, urge for eating and drinking		
(d)	Blind spot	Near the place where optic nerve leaves the eye	Rods and cones are present but inactive here		

38. Integration of the visual, tactile and auditory inputs occurs in the [Kerala PMT 2012]

Or

Crura cerebrae is found in

[DPMT 1993]

- (a) Peripheral nervous system
- (b) Corpus callosum
- (c) Limbic system
- (d) Medulla oblongata
- (e) Midbrain
- 39. Reflex action immediately involves

[NCERT; BHU 2003; Kerala CET 2005]

- (a) Spinal cord
- (b) Cerebellum
- (c) Medulla oblongata
- (d) Optical lobe
- 40. Parkinsonism is related with
- [CBSE PMT 2001]
- (a) Brain
- (b) Spinal cord
- (c) Cranial nerves
- (d) Spinal nerves

Hearing is controlled by

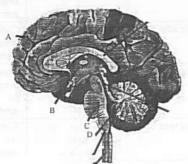

[MH CET 2005]

- (a) Cerebral lobes
- (b) Hypothalamus
- (c) Temporal lobe
- (d) Cerebellum
- In rabbit, optic lobes are small because the eye sight is 42. [RPMT 2001] controlled by
 - (a) Temporal lobe
- (b) Occipital lobe
- (c) Frontal lobe
- (d) Parietal lobe
- All spinal nerves are 43
- [RPMT 1999]
- (a) Motor
- (b) Sensory
- (c) Mixed
- (d) None of the above
- The correct sequence of meninges from outer to the inner [DPMT 2007] side is
 - (a) Arachnoid piamater duramater
 - (b) Arachnoid duramater piamater
 - (c) Piamater arachnoid duramater
 - (d) Duramater arachnoid piamater
- Body posture, equilibrium and rapid muscular activities are 45. controlled by [AIIMS 1993; MP PMT 1995; MH CET 2006; WB JEE 2008; Odisha JEE 2012]

Or

The part of human hind brain that is responsible for hand [Odisha JEE 2009] eye coordination is

- (a) Cerebellum
- (b) Thalamus
- (c) Hippocampus
- (d) Temporal lobe of cerebrum
- 46. A sagittal section of human brain is shown here. Identify at least two labels from A-D

[NEET (Karnataka) 2013]

- (a) C-Mid brain, D-Cerebellum
- (b) A-Cerebrum, C-Pons
- (c) B-Corpus callosum, D-Medulla
- (d) A-Cerebral hemispheres, B-Cerebellum
- 47. How many cranial nerves found in the amniota [RPMT 2001]
 - (a) 6 pairs
- (b) 8 pairs
- (c) 12 pairs
- (d) 10 pairs
- Which of the following cranial nerves is not a motor nerve

[MP PMT 2004]

(a) II

(b) III

(c) IV

- (d) XII
- 49. What is found in the periphery of spinal cord[MP PMT 1996]
 - (a) Grey matter
- (b) Myelinated nerve
- (c) White matter
- (d) Notochord

- Which foramen is paired in mammalian brain [MP PMT 2009] 50.
 - (a) Foramen of Luschka
- (b) Foramen of Magendie
- (c) Foramen of Monro
- (d) Inter-ventricular foramen
- Which one of the following pairs of structures distinguishes a [CBSE PMT 2007] nerve cell from other types of cell
 - (a) Perikaryon and dendrites
 - (b) Vacuoles and fibres
 - (c) Flagellum and medullary sheath
 - (d) Nucleus and mitochondria
- Which one of the following cranial nerves is carrying the 52. nerve fibres originating from the Edinger-Westphal nucleus

[WB JEE 2010]

- (a) Oculomotor
- (b) Trochlear
- (c) Abducens
- (d) Vagus
- Among the following characteristics, indicate the correct combinations applicable to conditional reflex
 - P. Acquired by practice or learning
 - Q. Not acquired by birth
 - R. Does not abolish by lack of practice
 - S. Participation of cerebral cortex
 - T. Originates spontaneously
- [WB JEE 2012]

- (a) P, Q, R
- (b) P, Q, S
- (c) P, R, T
- (d) Q, R, T
- How many laminae are present in the grey matter of spinal 54. [WB JEE 2010]
 - (a) Four
- (b) Six
- (c) Eight
- (d) Ten
- Which brain structure in rabbit is directly vision related 55.

[BHU 2003]

- (a) Corpus albicans
- (b) Hippocampal lobe
- (c) Corpus callosum
- (d) Corpora quadrigemina
- A boy learns typewriting and harmonium at the same time. 56. He finds harmonium more easy to learn. This is
 - (a) Conditioned reflex
- (b) Short term homeostasis
- (c) Long term homeostasis (d) Residual learning
- Which of the following is not related to the autonomic 57. [WB JEE 2010] nervous system
 - (a) Peristalsis
- (b) Digestion
- (c) Excretion

58.

- (d) Memory and learning
- (a) Reissner's membrane
- Which is thickened to form organ of Corti [MP PMT 2009] (b) Basilar membrane
 - (c) Tectorial membrane
- (d) All of the above
- Which is a wrong relation 59
 - (a) Conditioned reflex Hodgkins
 - (b) Blood circulation -W. Harvey
 - (c) DNA double helix model Watson and Crick
 - (d) None
- Which of the following is the immediate covering of a nerve 60. [MP PMT 1992] fibre
 - (a) Sarcoplasm
- (b) Perineurium
- (c) Epineurium
- (d) Endoneurium

Choroid plexus is a network of [KCET 2004] 127. Which one of the following cranial nerves is a (a) Capillaries (b) Muscle fibres parasympathetic nerve [WB JEE 2016] (c) Nerves (d) Lymph versels (a) Facial (b) Auditory 115. Nissl's granules are absent in [CPMT 2001: DPMT 20041 (c) Abducens (d) Vagus (a) Axon (b) Cuton Biochemical aspect of nervous physiology (c) Dendron (d) Both 'a' and 'b' 116. Broca's area is situated in Reflex arc consists of **[WB JEE 2008]** 1. [Odisha JEE 2008] (a) Frontal lobe (a) Motor nerve (b) Parietal lobe (c) Temporal lobe (b) Sensory nerve (d) Occipital lobe (c) Both sensory and motor nerves 117. Function of sympathetic nervous system is to (d) None of these [CPMT 1994; CBSE PMT 1999; RPMT 2006] 2. Given below is a table comparing the effects of sympathetic (a) Decrease heart beat (b) Increase heart beat and parasympathetic nervous system for four features (a-d). (c) Contract respiratory organ (d) Secrete saliva which one feature is correctly described [AIIMS 2008, 13] 118. The 3rd, 6th and 11th cranial nerves are Feature Sympathetic Parasympathetic [BHU 1995; AFMC 2000; Pb. PMT 2000; CPMT 2001] Nervous system Nervous System (a) Occulomotor, trigeminal, spinal (a) Salivary Stimulates Inhibits secretion gland secretion (b) Optic, facial, spinal Pupil of (b) Dilate (c) Occulomotor, abducens, spinal Constricts the eye (d) Trichlear, abducens, vagus Heart Decreases Increases 119. Which of the following connect lateral ventricle of diocoel in rate brain with third ventricle [BHU 1995; Pb. PMT 1999; Intestinal Stimulates Inhibits MP PMT 2003; Odisha JEE 20101 peristalsis (a) Iter (b) Foramen of Monro 3. Preparation of the type of stimulus depends on the (c) Corpus striatum (d) Filum terminale [AIIMS 1992] 120. Sub-arachnoid space is found in (a) Strength of the nerve impulse [RPMT 1995] (b) Specificity of connection to receptor organs Or The arachnoid membrane covers the (c) Rate of the nerve impulse [MP PMT 2000] (d) Ionic change moving in and out of the nerve (a) Piamater (b) Durameter (c) Blastocoel 4. The following hormones are neurotransmitters (d) None of the above [CBSE PMT 1992; Bihar CECE 2006; MP PMT 2013] 121. The primary visual area is located in [KCET 2004] (a) Acetylcholine and secretin (a) Temporal lobe (b) Occipital lobe (b) Cholecystokinin and acetylcholine (c) Frontal lobe (d) Parietal lobe (c) Adrenalin and acetylcholine 122. If the sympathetic nerve to the heart is cut-off, the heart beat (d) Cholecystokinin and adrenalin [MP PMT 1998] Which of the following is not an effect of the sympathetic (a) Increase 5. (b) Decrease (c) Remains same nervous system (d) Stop [AMU (Med.) 2010] 123. The cranial nerves which control eye-ball movement are (a) Dilation of pupil (b) Inhibition of peristalsis [EAMCET 1998; CPMT 2000] (a) 4, 6 and 7 (b) 3, 4 and 6 (c) Elevation of blood pressure

(c) 2, 3 and 5

(d) 5, 8 and 9

- During the transmission of nerve impulse, which of the [MP PMT 2002] following takes place
 - (a) Flux of Na+ inwards and K+ outwards
 - (b) Flux of K+ inwards and Na+ outwards
 - (c) Flux of K+ inwards and Na+ inwards
 - (d) Flux of K+ outwards and Na+ outwards
- During the propagation of a nerve impulse, the action 7. potential results from the movement of [CBSE PMT 2008]
 - (a) K+ ions from intracellular fluid to extracellular fluid
 - (b) Na+ ions from extracellular fluid to intracellular fluid
 - (c) K+ ions from extracellular fluid to intracellular fluid
 - (d) Na+ ions from intracellular fluid to extracellular fluid
- How many pairs of cranial nerves originate from the brain of R. [Kerala PMT 2008]
 - (a) 12
- (b) 8

(c) 9

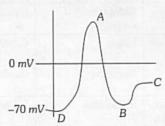

(d) 11

- (e) 10
- The potential maintained across the neuron membrane 9 during the resting state is [Kerala PMT 2008; AIIMS 2009]
 - (a) $+ 70 \, \text{mV}$
- (b) $-70 \, \text{mV}$
- (c) 0.5 V
- (d) $-30 \, \text{mV}$
- (e) $+ 30 \, \text{mV}$
- The cutaneous plexus and the papillary plexus consist of

[DUMET 2009]

- (a) A network of nerves to provide dermal sensation
- (b) A network of arteries to provide dermal supply
- (c) Specialized cells for cutaneous sensations
- (d) Gland cells that release cutaneous secretions

11.

Identify the region where all Na+ channels are reactivated but closed and all K+ channels are closed [EAMCET 2009]

(a) D

(b) C

- (d) A
- Which one of the following does not act as a neurotransmitter [CBSE PMT 2006; WB JEE 2009]
 - (a) Norepinephrine
- (b) Cortisone/Tyrosine
- (c) Acetylcholine
- (d) Epinephrine
- The chemical causing the transmission of nerve impulse 13. [KCET 1994; across synapses is

BHU 1999, 2008; CBSE PMT 2000; AFMC 2001, 08; DPMT 2003; BVP 2004; CPMT 2009]

Or

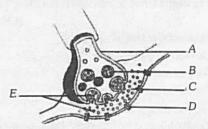

The neurotransmitter which communicates between two neurons or between a neuron and a muscle is

[MP PMT 1993, 95; BHU 1995; DPMT 2004; WB JEE 2016]

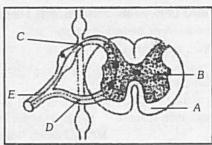

- (a) Acetylcholine
- (b) Cholinesterase
- (c) Choline
- (d) Acetic acid

- The action potential of a nerve cell is 14.
 - (a) 45 mV
- (b) 55 mV
- (c) 80 mV
- (d) 75 mV
- In the following diagram showing axon terminal and synapse, A, B, C, D and E respectively represents

[Kerala PMT 2010; NEET 2013; NEET (Karnataka) 2013]

- (a) Axon terminal, synaptic cleft, synaptic vesicles, neurotransmitters and receptors
- (b) Axon terminal, synaptic vesicles, synaptic cleft, receptors and neurotransmitters
- (c) Synaptic cleft, synaptic vesicles, axon terminal, neurotransmitters and receptors
- (d) Synaptic cleft, axon terminal, synaptic vesicles, neurotransmitters and receptors
- (e) Synaptic vesicles, axon terminal, synaptic cleft, receptors and neurotransmitters
- 16. In a cross section of the spinal cord A, B, C, D and E [Kerala PMT 2009] represents

- (a) A white matter, B grey matter, C dorsal root, D - ventral root, E - spinal nerve
- (b) A white matter, B grey matter, C ventral root, D - dorsal root, E - spinal nerve
- (c) A grey matter, B white matter, C ventral root D - dorsal root, E - spinal nerve
- (d) A grey matter, B white matter, C dorsal root, D - ventral root, E - spinal nerve
- (e) A white matter, B grey matter, C spinal nerve, D - ventral root, E - dorsal root
- The blood-brain barrier 17.

[J & K CET 2012]

- (a) Consists of both anatomical and physiological factors
- (b) Regulates to some extent the passage of substances from the blood to the interstitial fluid of the brain
- (c) Is anatomically related to the formation of tight junctions between adjacent capillary endothelial cells
- (d) All of the above are correct

-8

	UNIVERSAL
и	BOOK DEPOT 1960

18. During synaptic transmission of nerve neurotransmitter (p) is released from synaptic vesicles by the action of ions (Q). Choose the correct P and Q

[WB JEE 2012]

- (a) P = acetylcholine, Q = Ca⁺⁺
- (b) P = acetylcholine, Q = Na+
- (c) P = GABA, $Q = Na^+$
- (d) P = cholinesterase, Q= Ca++
- 19. An investigator places an isolated neuron in a calcium free medium, gives the neuron a suprathreshold stimulus and then performs an assay to test whether neurotransmitter is released into the medium. Which of the following outcomes would you predict [J & K CET 2012]
 - (a) No neurotransmitter is detected since influx of calcium into the synaptic knob is required for neurotransmitter
 - (b) No neurotransmitter is detected since influx of calcium is required in order for the neuron to conduct an action potential
 - (c) Neurotransmitter is detected since calcium is not required for action potential conduction and the initial stimulus was suprathreshold
 - (d) We cannot predict the outcome without knowing whether the neuron was myelinated
- 20. Which option is correct for the correctly matched groups for the column I, column II and column III [GUJCET 2014]

U	Column I	Column II	Column III
(a)	Resting membrane potential	i. Na+ channel get open	e. Na ⁺ and K ⁺ pumps are responsible for it
(b)	Action potential	ii. Na+ channel is closed	f. Last for very short time
(c)	Depolarization	iii. Na ⁺ ions are more on outer side	g. K ⁺ ions move on outerside of membrane
(d)	Repolarization	iv. Na ⁺ ions are more on inner side of membrane	h. Positive charge on inner side of membrane

- (a) (a ii h) (b i g) (c iii e) (d iv- f)
- (b) (a iii e) (b iv f) (c i h) (d ii g)
- (c) (a iv f) (b iii e) (c i e) (d ii- h)
- (d) (a iv e) (b iii f) (c ii g) (d i- g)
- The release of chemical messenger from synaptic vesicles is 21. under the influence of these ion(s)
 - (a) C1-
- (b) Fe+ + and S++
- (c) Ca++
- (d) Mg^{++} and Sr^{++}
- The potential difference between outside and inside of a nerve before excitation is known as

[MP PMT 1996; Kerala PMT 2010]

- (a) Resting potential
- (b) Action potential
- (c) Spike potential
- (d) Reaction potential
- Depolarization of a stimulated nerve is maintained by

[MP PMT 1996]

- (a) Ca++
- (b) C1-
- (c) Mg++
- (d) K+

- During transmission of nerve impulse the potential inside membrane has the following type of charge [CBSE PMT 2007]
 - (a) First positive, then negative and back positive
 - (b) First negative then positive and back negative
 - (c) First positive then negative and remain negative
 - (d) First negative then positive and remain positive
- Nerve gas affects neuromuscular activity by
 - (a) Blocking the acetylcholine receptor sites
 - (b) Inhibiting the release of acetylcholine
 - (c) Inhibiting acetylcholinesterase
 - (d) Enhancing the release of acetylcholine
- 26. Destruction of the anterior horn cell of the spinal cord would result in loss of [AIPMT 2015]
 - (a) Voluntary motor Impulses
 - (b) Commissural impulses
 - (c) Integrating impulses
 - (d) Sensory impulses
- Which of the following is not a type of neuroglial cells

[Odisha JEE 2012]

- (a) Astrocytes
- (b) Oligodendrocytes
- (c) Microglia
- (d) Chondrocytes
- 28. Which of the following option is correct for the statement 'X' and 'Y'

Statement 'X' - Immediately after repolarization, ionic imbalance is created on both the sides of the nerve fibre Statement 'Y' - During repolarization K+ ion channel open up and K⁺ ion moves on innerside of plasma membrane

[GUJCET 2014]

- (a) Statements 'X' and 'Y' are correct and 'Y' is correct for
- (b) Statements 'X' and 'Y' are correct and 'Y' is not correct for 'X'
- (c) Statement 'X' is correct and 'Y' is wrong
- (d) Statement 'X' is wrong and 'Y' is correct
- Afferent nerve fibres carry impulses from [CBSE PMT 1992] 29.
 - (a) Effector organs to central nervous system
 - (b) Receptors to central nervous system
 - (c) Central nervous system to muscles
 - (d) Central nervous system to receptors
- 30. On nerve fibres to prevent leakage of an impulse layer of is found [CPMT 1993]
 - (a) Schwann cells
- (b) Neurilemma
- (c) Axons
- (d) Myelin sheath
- All sensory pathways to the cerebral cortex synapse at the

[AMU (Med.) 2009]

- (a) Pons
- (b) Hypothalamus
- (c) Thalamus
- (d) Cerebellum
- 32. These processes occurs during repolarization of nerve fibre
 - (i) Open Na+ channel
- (ii) Closed Na+ channel

[GUJCET 2007; DPMT 2007]

- (iii) Closed K+ channel
- (iv) Open K+ channel

- (b) (i) and (iii)
- (a) (ii) and (iv)
- (c) (ii) and (iii)
- (d) (i) and (ii)

43. Intercellular communication in multicellular organism occurs Which of the following is not a reflex action [BHU 2012] [BHU 2000; CPMT 2004] (a) Blinking of eyes (a) Digestive system only (b) Salivation (b) Respiratory system only (c) Sweating (c) Nervous system only (d) Withdrawal of hand on touching some hot object (d) Both nervous and endocrine system Nerve impulse travels faster in [CPMT 1994; AFMC 2008] Which of the following substances leads to the inhibition of 44. (b) Non-medullated nerve (a) Medullated nerve [CPMT 2004] central nervous system (d) Spinal nerve (c) Cranial nerve (b) GABA (a) Glycine 35. The amount of CSF in the cranial cavity is [WB JEE 2011] (c) Nor epinephrine (d) Both 'a' and 'b' (b) 140 ml (a) 500 ml Transmission of nerve impulse, across the synapse is 45. (c) 1 litre (d) 1.5 ml accomplished by [Pb. PMT 2004] 36. Synaptic vesicle is found in [DPMT 2007] (a) Release of ions (a) Pre-synaptic neuron (b) Post synaptic neuron (b) Release of neurotransmitters (c) Synaptic left (d) None of these (c) Movement of water Nerve impulse initiates with the movements of 37. (d) Movement of Na+ and K+ [BHU 1999; MH CET 2001; MP PMT 2003; RPMT 2006] 46. The brain stem is made up of [KCET 2011] Or (a) Midbrain, pons, cerebellum Neuron becomes an electrically charged cell by the diffusion (b) Midbrain, pons, medulla oblongata [CPMT 1994; MP PMT 2006] of (c) Diencephalon, medulla oblongata, cerebellum (b) Mg+ (a) K+ (d) Cerebellum, cerebrum, medulla oblongata 47. Parkinson's disease (characterized by tremors and (d) Na+ (c) Ca+ progressive rigidity of limbs) is cause by degeneration of Sodium-potassium pump is [RPMT 2001] 38. brain neurons that are involved in movement control and (a) A hormone (b) An enzyme make use of neurotransmitter [CBSE PMT 2005; WB JEE 2011] (c) A protein carrier (d) An organelle (b) Nor epinephrine For visual sense, the nerve impulse is generated by (a) Acetylcholine (c) Dopamine (d) GABA [RPMT 2001] One of the example of the action of the autonomous 48. (a) Depolarisation [CBSE PMT 2005] nervous system is (b) Repolarisation (a) Knee-jerk response (b) Pupillary reflex (c) Hyper polarisation (c) Swallowing of food (d) Peristalsis of the intestines (d) Depolarisation and repolarisation In parasympathetic nervous system which of the following is 49. [BHU 2005] released 40. The enzyme required for the conduction of nerve impulses (a) Epinephrine (b) Nor epinephrine [CBSE PMT 2001] across synapse is (c) Serotonin (d) Acetylcholine (a) Peroxidase (b) Choline acetylase The following is the scheme showing the path of reflex arc. (c) Ascorbic acid oxidase (d) Succinic dehydrogenase Identify the different labellings A, B, C, D, E, F in the reflex Unidirectional transmission of a nerve impulse through [KCET 2010] nerve fibre is due to the fact that [AIIMS 2004] (a) Nerve fibre is insulated by a medullary sheath (b) Sodium pump starts operating only at the cyton and then continues into the nerve fibre (c) Neurotransmitters are released by dendrites and not by D axon endings F (d) Neurotransmitters are released by the axon endings and B C D F not by dendrites Effector Sensory Motor Receptor Response Stimulus 42. Cerebrospinal fluid is present [Kerala PMT 2004] nerve nerve Sensory Motor Effector Response (b) Stimulus Receptor (a) Beneath the piamater nerve nerve (b) Between piamater and arachnoid mater Stimulus Effector Motor Sensory Receptor Response (c) Between arachnoid and duramater nerve nerve (d) In extra duramater (d) Stimulus Motor Sensory Effector Response Receptor nerve nerve (e) Between the duramater and cranium

51. Hypothalamus does not control

[NCERT; Kerala CET 2005; WB JEE 2010]

- (a) Hunger and satiety
- (b) Thermoregulation
- (c) Libido
- (d) Creative thinking and consciousness
- (e) Osmoregulation
- **52.** You are watching a horror movie and you notice that your heart is beating fast and mouth is dry. It is because of

[Kerala CET 2005]

- (a) Fight and flight response
- (b) Autonomic nervous system
- (c) Sympathetic nervous system
- (d) Both (a) and (c)
- (e) Parasympathetic nervous system
- **53.** Which one of the following reflex do not include innervation of brain [Odisha JEE 2005]
 - (a) Spinal reflex
- (b) Cranial reflex
- (c) Afferent reflex
- (d) Efferent reflex
- 54. Which of the statements about the mechanism of muscle contraction are correct
 - Acetylcholine is released when the neural signal reaches the motor end plate
 - (II) Muscle contraction is initiated by a signal sent by CNS via a sensory neuron
 - (III) During muscle contraction, isotropic band gets elongated
 - (IV) Repeated activation of the muscles can lead to lactic acid accumulation

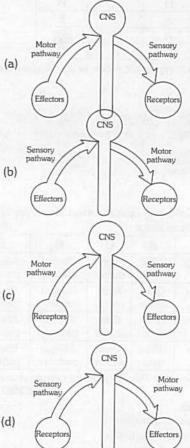

[Kerala PMT 2011]

- (a) I and IV are correct
- (b) I and III are correct
- (c) II and III are correct
- (d) I, II and III are correct
- (e) I and II are correct
- 55. In a modulated nerve fibre, the conduction of impulse is faster due to the presence of [Odisha JEE 2010]
 - (a) Pericytes
 - (b) Endoneurium and epineurium
 - (c) Myelin sheath and nodes of Ranvier
 - (d) Nissl's granules
- 56. When a neuron is in resting state i.e. not conducting any impules, the axonal membrane is [CBSE PMT (Pre.) 2011]
 - (a) Comparatively more permeable to K+ ions and nearly impermeable to Na+ ions
 - (b) Comparatively more permeable to Na+ ions and nearly impermeable to K+ ions
 - (c) Equally permeable to both Na+ and K+ ions
 - (d) Impermeable to both Na+ and K+ ions

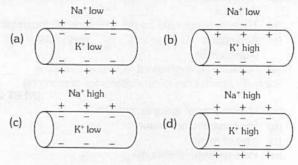

- 57. Which of the following statement are correct and incorrect
 - 1. Synaptic cleft of neurons secrete adrenaline
 - Myelinated nerve fibres are enveloped with Schwann cells, which form a myelin sheath around the axon
 - Non-myelinated nerve fibre is enclosed by a Schwann cell that does not form a myelin sheath
 - Spinal cord and cranial nerves are made of nonmyelinated nerve fibres of the four statements

[Kerala PMT 2011]

- (a) 1, 2 are correct but 3 and 4 are incorrect
- (b) 1, 2 and 3 are correct but 4 is incorrect
- (c) 3 and 4 are correct but 1 and 2 are incorrect
- (d) 1 and 4 are correct while 2 and 3 are incorrect
- (e) 2 and 3 are correct while 1 and 4 are incorrect
- **58.** Choose the correct diagram which represent the flow of information through the nervous system [NCERT]

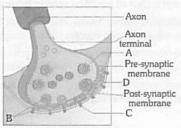

59. Which diagram shows the distribution of Na⁺ and K⁺ ions in a section of non-myelinated axon which is at resting potential [NCERT]

60. Consider the diagram of synapse

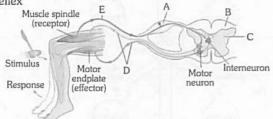

- The numbered label indicate the location of the receptor molecules
- The number points to a synaptic vesicles
- III. The number points to neurotransmitter

IV. The number points to synaptic cleft

[NCERT]

	I	II	III	IV
(a)	С	D	A	В
(b)	С	A	D	В
(c)	В	A	C	D
(d)	С	Α	В	D

The given diagram represent reflex action shows knee jerk reflex

In which of the following option correct words for all the 5 blanks (A to E) are illustrate

	A	В	C	D	E
(a)	Ventral root ganglion	White matter	Gray matter	Efferent pathway	Afferent pathway
(b)	Dorsal root ganglion	Gray matter	White matter	Efferent pathway	Afferent pathway
(c)	Dorsal root ganglion	White matter	Gray matter	Efferent pathway	Afferent pathway
(d)	Dorsal root ganglion	White matter	Gray matter	Afferent pathway	Efferent pathway

- Stimulation of a muscle fibre by a motor neuron occurs at [CBSE PMT 2014]
 - (a) The myofibril
 - The sacroplasmic reticulum (b)
 - The neuromuscular junction
 - (d) The transverse tubules
- 63. Select the correct combination statements for the neurotransmitters [WB JEE 2016]
 - (a) Acetylcholine is inactivated mainly by presynaptic reuptake
 - (b) Tyrosine is essential for the formation of dopamine
 - (c) Adrenaline is formed by methylation of noradrenaline
 - (d) Serotonin is synthesized from phenylalanine
- Receptor sites for neurotransmitters are presents on

[NEET 2017]

- (a) Membranes of synaptic vesicles
- (b) Pre-synaptic membrane
- (c) Tips of axons
- (d) Post-synaptic membrane

Myelin sheath is produced by

Or

Myelin of the nerve fibres of the central nervous system is produced and maintained by [AMU (Med.) 2009]

- (a) Schwann cell and Oligodendrocytes
- (b) Astrocytes and Schwann cells
- (c) Oligodendrocytes and Osteoclasts
- (d) Osteoclasts and Astrocytes

Different types of Receptors

- The pacinian corpuscle present in the skin is for [DPMT 1993; MH CET 2006; AMU (Med.) 2010]
 - (a) Pain
- (b) Pressure
- (c) Movement
- (d) Temperature
- 2. Colour blindness results from
- [MP PMT 1996: AFMC 1997; WB JEE 2010]
- (a) Absence of rods
- (b) Absence of cones
- (c) Absence of eyelids
- (d) Inverted retina
- 3. In fishes the lateral line receptors are neuromast organs. These are [AFMC 2006]
 - (a) Olfactoreceptors
- (b) Gustatoreceptors
- (c) Rheoreceptors
- (d) Chemoreceptors
- Jacobson's organ is concerned with 4. [CPMT 1994; Kerala PMT 2004; MH CET 2006; WB JEE 2010]
 - (a) Smell
- (b) Burrowing
- (c) Touch
- (d) Sight
- (e) Chemoreception
- Jacobson's organ in man
 - [MP PMT 1995; AFMC 2001]

[MP PMT 2000]

[AIIMS 1998]

- (a) Functions as smelling organs
- (b) Functions as gustatory organ
- (c) Is a vestigeal organ
- (d) Functions as pain sensory organ
- Sonar system is found only in
 - (a) Bats
 - (b) Whales
 - (c) Bats and whales (d) Otter
- Osphradium of Pila globosa is [APMEE 1999; CBSE PMT 2000; BHU 2000, 01; CPMT 2001; **DPMT 20041**
 - (a) Photoreceptor
- (b) Chemoreceptor
- (c) Thermoreceptor
- (d) Tangoreceptor
- 8. Meissner's corpuscles are located in
- - [CPMT 1992, 2002; AIIMS 1993]
 - (a) Pancreas and secrete trypsinogen
 - (b) Adrenal and secrete epinephrin
 - (c) Spleen and destroy worn out erythrocytes
 - (d) Skin and perceive gentle pressure
- Vibrissae are associated with the function of [JIPMER 1993]
 - (a) Thermoregulation
- (b) Gustation
- (c) Tactile perception Sensation of stomach pain is due to
- (d) Reproduction
- 10. (a) Interoceptors
- (b) Exteroceptors
- (c) Proprioceptors
- (d) Teloreceptors
- 11. The sweet and acidic tastes are better detected by
 - (a) Tip of the tongue
- (b) Base of the tongue
- (c) Middle of the tongue
- (d) Lateral sides of the tongue
- Proprioceptors are those, which give the sense of
 - [MP PMT 2001; CBSE PMT 2001]
 - (a) Chemicals
 - (b) Temperature
 - (c) Taste
 - (d) Changes in the internal environment of the body

UNIVERSAL BOOK DEPOT 1960

13. Sea gulls excrete excess of NaCl from

[BHU 2005]

- (a) Liver
- (b) Lungs
- (c) Nasal cavity
- (d) Kidney
- 14. Animals which have well developed echolocation system like that of bats [KCET 1994; Kerala CET 2002;

CPMT 2003; Kerala PMT 2004; J & K CET 2008]

- (a) Wild cats
- (b) Beavers
- (c) Primates
- (d) Whales and dolphins
- (e) Hedgehogs
- 15. The receptors found in the muscles, tendons and joints are

[MP PMT 1996, 2002]

- (a) Teloreceptors
- (b) Proprioceptors
- (c) Interoceptors
- (d) None of these

Eye

 Which part of the eye controls the amount of light entering in it [MP PMT 1992; CPMT 1993; DPMT 1993]

Or

The black pigment in the eye which reduces the internal reflection is located in [AIIMS 1998]

- (a) Cornea
- (b) Ciliary body
- (c) Iris
- (d) Suspensory ligament
- Which of the following prevents internal reflection of light within the eye [RPMT 2005]

Or

Coloured (Pigmented) layer of eye is

[RPMT 1995]

- (a) Cornea
- (b) Choroid
- (c) Sclera
- (d) Conjunctiva
- 3. In the chemistry of vision in mammals, the photosensitive substance is called [CBSE PMT 1997]

Or

The visual pigment in rods of retina of vertebrate eye which is responsible for detection of light is

Or

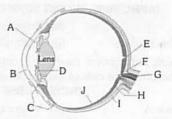

It is present in rods and useful in night vision [GUJCET 2007]

- (a) Selerotin
- (b) Retinol
- (c) Rhodopsin
- (d) Melanin
- In mammalian eye, the 'fovea' is the centre of the visual field, where [BHU 2003; AIPMT 2015; WB JEE 2016]
 - (a) The optic nerve leaves the eye
 - (b) Only rods are present
 - (c) More rods than cones are found
 - (d) High density of cones occur, but has no rods
- Which one of the following is correct pairing of a body part and the kind of muscle tissue that moves it

[CBSE PMT 2009]

- (a) Heart wall involuntary unstriated muscle
- (b) Biceps of upper arm Smooth muscle fibres upper arm
- (c) Abdominal wall Smooth muscle
- (d) Iris Involuntary smooth muscle
- In the following abnormalities of the eye which one is a serious condition that leads to blindness [Kerala CET 2003]
 - (a) Presbyopia
- (b) Myopia
- (c) Hypermetropia
- (d) Glaucoma

7. Study the following figure

- I. Carries nerve signals to the brain
- Regulates the size of the pupil to let more or less light into the eye
- III. Changes the shape of the lens
- IV. Photoreceptors are highly concentrated at this center of focus

The correct match of the above functions with parts of the eye indicated by letters is [NCERT]

- (a) I G, II D, III C, IV E (b) I A, II C, III E, IV G
- (c) I J, II G, III F, IV C (d) I B, II D, III F, IV H
- 8. Given below is a diagrammatic cross section of a single loop of human cochlea

[CBSE PMT 2008; AIIMS 2012]

Which one of the following options correctly represents the names of three different parts

- (a) D : Sensory hair cells, A : Endolymph, B : Tectorial membrane
- (b) A: Perilymph, B: Tectorial membrane, C: Endolymph
- (c) B: Tectorial membrane, C: Perilymph, D: Secretory cells
- (d) C: Endolymph, D: Sensory hair cells, A: Serum
- 9. In the blind spot where the optic nerves leave the eye

[NCERT; AFMC 2006]

- (a) Rods and cones are absent
- (b) Only cones are present
- (c) Only rods are present
- (d) Special neurons are present
- Dark adaptation in human eye involves [AMU (Med.) 2012]
 - (a) Conversion of 11 cis retinene to trans retinene
 - (b) Conversion of trans retinene into 11 cis retinene
 - (c) Decomposition of rhodopsin into retinene
 - (d) Decomposition of rhodopsin to scotopsin
- 1. Cavity of vitreous humour in the eyes are situated

[AIIMS 1993]

- (a) Behind the lens
- (b) Infront of the lens
- (c) Behind the retina
- (d) Between the retina and sclerotic

100	1253	1.77			
Lit	WV	ER.	SA	Ŀ	

12.	The rods and cones of the eye retinal layer are modified	22.	Iris of an eye is an extension of [NCERT]
	[AFMC 2005; MP PMT 2009; Odisha JEE 2012]		(a) Cornea (b) Sclerotic
	(a) Hair (b) Unipolar neurons		(c) Retina (d) Both choroid and retina
	(c) Bipolar neurons (d) Multipolar neurons	23.	
13.	The purplish red pigment rhodopsin contained in the rods		(a) Vulture (b) Frog
	type of photoreceptor cells of the human eye, is a derivative	0.4	(c) Shark (d) Bat
	of [NCERT; CBSE PMT (Pre.) 2011]	24.	The optic lobes in humans are represented by the corpora [NCERT; AMU (Med.) 2010, 12]
	(a) Vitamin A (b) Vitamin B ₁		(a) Bigemina (b) Arenacea
	(c) Vitamin C (d) Vitamin D		(c) Striata (d) Quadrigemina
14.	lodopsin is a light sensitive (photosensitive) pigment and is	25.	Sensory neurons of retina of eye are [Odisha JEE 2009]
	present in the [CPMT 1992, 93; Bihar CECE 2006; AFMC 2010; DUMET 2010]		(a) Rods and cones
	(a) Rods (b) Cones		(b) Maculae and cristae
	(c) Neuroglia (d) Bipolar cells		(c) Pacinian and Ruffini's corpuscles
5.			(d) All of these
Э.		26.	The decoding and interpretation of visual information is
	(a) Optic disc (b) Periphery (c) Macula lutea (d) Fovea centralis		carried out by which part of the brain [Kerala PMT 2006]
			(a) Cerebellum (b) Frontal lobe
6.	Which function will be lost due to damage of occipital lobe [MH CET 2007; WB JEE 2011]		(c) Parietal lobe (d) Temporal lobe (e) Occipital lobe
	(a) Hearing (b) Speech	27.	Parts A, B, C and D of the human eye are shown in the
	(c) Vision (d) Memory		diagram. Select the option which gives correct identification
17.	UV radiation from sun causes which of the following		along with its functions/ characteristics
	disorder of eyes [BHU 2004]		
	(a) Cataract (b) Glaucoma		c A
	(c) Dilation pupil (d) Some defect of retina		YAL .
18.	Which one of the following is the correct difference between		Lens
	Rod Cells and Cone Cells of our retina [CBSE PMT 2008]		Iris
	Rod Cells Cone Cells		A
	(a) Overall Vision in poor Colour vision		[NEET 2013]
	function light and detailed vision in		(a) D – Choroid – its anterior part forms ciliary body
	bright light		(b) A – Retina – contains photo receptors-rods and cones
	(b) Distibution More Evenly		(c) B – Blind spot – has only a few rods and cones
	concentrated distributed all		(d) C - Aqueous chamber reflects the light which does not
	in centre of retina Over retina	-	pass through the lens
	(c) Visual acuity High Low	28.	Protein found in eye lens is [DPMT 2007]
	(d) Visual Iodopsin Rhodopsin		(a) Crystallin (b) Collagen
	pigment contained	29.	(c) Opsin (d) Rhodopsin The size of pupil is controlled by the [NCERT; DUMET 2009]
19.	Cornea transplant in humans is almost never rejected.	29.	(a) Ciliary muscles (b) Suspensory ligaments
	Because [CBSE PMT 1996, 2008]		(c) Cornea (d) Iris muscles
	(a) It is composed of enucleated cells	30.	Match the following
	(b) It is a non-living layer		Column I Column II
	(c) Its cells are least penetrabel by bacteria		(A) Fovea (1) Provides opening for entry of
	(d) It has no blood supply		a service remaining and a light remaining at the street of the street
20.	The function of iris in the eyes of frog is to [BHU 1999]		(B) Iris (2) Transduces RGB light
	(a) Refraction of light rays		(C) Pupil (3) Transmits information to CNS
	(b) Alter the size of the pupil		(D) Lens (4) Controls amount of light
	(c) Move the nictitating membrane		entering (5) Face of the state of
	(d) Move the lens forward and backward		(E) Optic nerve (5) Focuses light on the retina [NCERT; Kerala PMT 2009]

UNIVERSAL BOOK DEPOT 1960

31.	The muscles surrounding the pupil of rabbit's eye are [CPMT 2004]	44.	The human eye is sensitive only to light having wave length ranging from [JIPMER 2002
	(a) Unstriated and involuntary (b) Striated and voluntary		(a) 80 to 280 nanometres (b) 380 to 760 nanometres
	(c) Unstriated and voluntary (d) Striated and involuntary		(c) 780 to 870 nanometres (d) 880 to 980 nanometres
32.	In human beings the total visual field and the stereoscopic	45.	The number of occipital condyles in man is/are
02.	visual field respectively is [AMU (Med.) 2009]		[Kerala PMT 2010
			(a) One (b) Two
			(c) Three (d) Four
edi ir	(c) 180° and 26° (d) 140° and 52°		(e) Five
33.	The innermost layer of the human eye is [Kerala PMT 2010] (a) Choroid (b) Cornea	46.	The posterior part of the retina, which is just opposite to the lens is [AIIMS 2009]
	(c) Sclera (d) Retina		(a) Cornea (b) Yellow spot
	(e) Lens		(c) Area centralis (d) Both (b) and (c)
34.	The iris of eye is [RPMT 1999]	47.	In man, the image formation occur on retina for most bright
	(a) Photosensitive (b) Chemoreceptor		vision it should form on [RPMT 2001]
	(c) Calororeceptor (d) All		(a) At the place of entry of optic nerve
35.	The unit of photoreception, in a compound eye of		(b) Blind spot
	cockroach and other insects, is [Pb. PMT 1999]		(c) Yellow spot
	(a) Ctenidium (b) Osphradium	48.	(d) At the junction of ciliary body and lens Which of the following have "ommatidia" as unit of eye
	(c) Ommatidium (d) Rhabdome	40.	[RPMT 2001]
36.	In the myopia eye defect, the rays of light		(a) Pheretima (b) House fly
	[CBSE PMT 2000; AIIMS 2003]		(c) Pila (d) Sepia
	(a) Do not enter the eye at all	49.	Sensitive (pigmented) layer of eye is [NCERT:
	(b) Come to a focus at back of retina		[MP PMT 2006; Odisha JEE 2010]
	(c) Come to a focus in front of the retina		(a) Sclerotic (b) Retina
	(d) Come to a focus in between retina & iris		(c) Cornea (d) None of these
37.	Only rods are present in the eyes of one of the following	50.	The cornea and lens of the mammalian eyes are both
	animals [MP PMT 2001]		(a) Richly supplied by nerves
	(a) Pigeon (b) Squirrel		(b) Richly supplied by blood vessels
	(c) Fowl (d) Owl		(c) Transparent and they diverge the light rays to form an
38.	Vitreous humour is seen in [CBSE PMT 1993]		image on retina
	(a) Ear (b) Eye		 (d) Transparent and they contribute in the formation of image on retina
	(c) Brain (d) Bone marrow	51.	Lens of eye retina is developed from [CPMT 1998]
39.	The space between the lens and the cornea of the human	01.	(a) Ectoderm (b) Mesoderm
0).	eye is [AIIMS 1993]		(c) Endoderm (d) Ecto-mesoderm
	(a) Vitreous chamber (b) Aqueous chamber	52.	Choroid is
	(c) Retina (d) Iris		(a) Middle layer of ear (b) Innermost layer of eye
40.	Glaucoma is an eye disease arising from[JIPMER 1993, 2002]		(c) Innermost layer of ear (d) Middle layer of eye
	(a) Increased pressure of fluid in eye ball	53.	As compared to rods the cones are times less sensitive
	(b) Elongation of eye ball		(a) 100 (b) 200
			(c) 300 (d) 400
	(c) Shortening of eye ball	54.	A 22 years student goes to his opthalamologist. He has
41	(d) Irregularity in the surface of cornea		problem in reading books because he is not able to contract
41.	The movement of eye ball is brought about by the		his [CPMT 2009]
	[DPMT 1993]		(a) Suspensory ligament (b) Pupil
	(a) Adductor muscle (b) Rectus muscle		(c) Iris (d) Ciliary muscles
40	(c) Biceps (d) Peroneus	55.	The lens and cornea is not having blood supply. So the
42.	The hollow of the eye is divided into aqueous chamber and		nutrients are supplied by [Kerala CET 2003]
	vitreous chamber by [DPMT 1993; MP PMT 2007]	40	(a) Retina (b) Blind spot
	(a) Optic nerve (b) Retina	276	(c) Vitreous body (d) Aqueous humour
12	(c) Lens (d) Iris	56.	Photosensitive compound in human eye is made up of
43.	The central opening of iris is called as [CBSE PMT 1993]		[NEET (Phase-I) 2016]
	(a) Pupil (b) Cornea		(a) Guanosine and Retinol (b) Opsin and Retinal
	(c) Lens (d) Fovea centralis		(c) Opsin and Retinol (d) Transducin and Retinene

988 Neural Control and Coordination Choose the correct statement [NEET (Phase-II) 2016] (a) Receptors do not produce graded potentials (b) Nociceptors respond to changes in pressure (c) Meissner's corpuscles are thermoreceptors (d) Photoreceptors in the human eye are depolarized during darkness and become hyperpolarized in response to the light stimulus 58. Which cell in the retina recognize colour [WB JEE 2016] (a) Rod cells (b) Cone cells (c) Both Rod and Cone cells (d) Epithelial cells Ear 1. Hearing in rabbit is better than frog. One reason for this is that rabbit has [MP PMT 1992] (a) Three semicircular canal (b) Vibratile tympanic membrane (c) Movable pinna (d) Both fenestra ovalis and eustachian tubes 2. Scala vestibuli is connected with [NCERT; MP PMT 1992] (a) Fenestra rotundus (b) Fenestra ovalis (c) Scala tympani (d) Scala media 3. Identify the correct sequence of organs/regions in the organization of human ear as an auditory mechanoreceptor [NCERT; Kerala PMT 2007] (a) Pinna - Cochlea - Tympanic membrane - Auditory canal - Malleus - Stapes - Incus - Auditory nerve (b) Pinna - Tympanic membrane - auditory canal - Incus -Malleus - Stapes - Cochlea - Auditory nerve (c) Pinna - Malleus - Incus - Stapes - Auditory canal -Tympanic membrane - Cochlea - Auditory nerve (d) Pinna - Tympanic membrane - Auditory canal -Cochlea - Malleus - Incus - Stapes - Auditory nerve (e) Pinna - Auditory canal - Tympanic membrane -Malleus - Incus - Stapes - Cochlea - Auditory nerve Statolith is an organ which helps in [DPMT 1993] (a) Vision (b) Equilibrium (c) Tactile stimulation (d) Chemical stimulation 5. Acoustic spots in frog is present in [CPMT 2002; RPMT 2005] (a) Ossious labyrinth (b) Carotid (c) Membranous labyrinth (d) All of these 6. The tympanic cavity is connected with the pharynx by (a) Columella (b) Ear ossicles (c) Eustachian tube (d) Fallopian tubes 7. Our ear can hear the frequency of sound waves [Kerala CET 2003] (a) 20 to 20,000 cycles/sec (b) 1000 to 2000 cycles/sec

(c) 5000 to 7000 cycles/sec

(d) 5000 to 10,000 cycles/sec

8. The perception of sound by a mammal involves the stimulation of the mechano receptors located in the internal [CPMT 1992] (a) On the organ of corti (b) On the Reissner's membrane (c) In the sacculus (d) In the semicircular canal 9. The true sense of equilibrium in mammals are situated in the [RPMT 2001] (a) Malleus (b) Utriculus (c) Eustachian tubes (d) Semicircular canal The bony labyrinth is filled with [NCERT; DPMT 1993] (b) Synovial fluid (a) Endolymph (c) Perilymph (d) Humour 11. Which part is not included in Cochlear duct [GUJCET 2015] (a) Reissner's membrane (b) Macula of Utricle (c) Scala Media (d) Tectorial membrane The kind of tissue that forms the supportive structure in our pinna (external sears) is also found in [CBSE PMT 2009] (a) Vertebrae (b) Nails (c) Ear ossicles (d) Tip of the nose 13. High frequency sound waves vibrate the basilar membrane [AMU (Med.) 2009; WB JEE 2016] (a) Near the oval window (b) Near the helicotrema (c) In the middle of cochlea (d) From oval window to helicotrema Eustachian tube connects [NCERT; CPMT 2009] (a) Pharynx with middle ear (b) Middle ear with internal ear (c) Middle ear with external ear (d) External ear with internal ear 15. Utriculus is the part of internal ear or membranous labyrinth (a) Lower chamber and is concerned with maintenance of (b) Lower chamber and is concerned with transmission of sound waves (c) Upper chamber and is concerned with maintenance of equilibrium (d) Upper chamber and is concerned with perception 16. Internal ear is filled with [AFMC 2005] (a) Perilymph (b) Endolymph (c) Lymph (d) Both (a) and (b) 17. Vibrations of fenestra ovalis are transmitted to (a) Perilymph of scala vestibuli (b) Perilymph of scala tympani (c) Endolymph of scala media (d) Endolymph of scala vestibuli Canal joining middle ear with buccal cavity is [MP PMT 2001] (a) Inguinal canal (b) Eustachian canal

(c) Haversian canal

19. Malleus is present in the

(a) Inner ear

(c) Middle ear

(d) Aquaduct of Sylvius

(b) Outer ear

(d) Eye

[CBSE PMT 1993]

UNIVERSAL BOOK DEPOT 1960

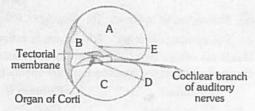

20. Which part of the human ear plays no role in hearing as such but is otherwise very much required

[NCERT; CBSE PMT (Pre.) 2012] Or

Which of the following is balancing organ

[DPMT 2007; Kerala PMT 2010; AIPMT (Cancelled) 2015]

- (a) Eustachian tube
- (b) Organ of corti
- (c) Vestibular apparatus
- (d) Ear ossicles
- 21. The sense of equilibrium by ear is the function of
 - (a) Sensory cells of the organ of corti
 - (b) Sensory crista of the ampulla
 - (c) Tectorial membrane of cochlea
 - (d) Basilar membrane of cochlea
- 22. Consider the given sectional view of Cochlea. Identify A, B, C, D and E [NCERT: MH CET 2015]

- (a) A Scala vestibuli, B Scala media, C Scala tympani,
 - D Reissner's membrane, E Basilar membrane
- (b) A Scala tympani, B Scala media, C Scala vestibuli,
 - D Basilar membrane, E Reissner's membrane
- (c) A Scala media, B Scala vestibuli, C Scala tympani,
 - D Basilar membrane, E Reissner's membrane
- (d) A Scala vestibuli, B Scala media, C Scala tympani,
 D Basilar membrane, E Reissner's membrane
- 23. Columella auris is a modified

[CBSE PMT 1992]

- (a) Articular
- (b) Sphenthmoid
- (c) Hyomandibular
- (d) Quadrate
- 24. A person going upto 10,000 feet high in a hot air balloon may develop severe pain in the ear due to
 - (a) Blocked eustachian tube
 - (b) Rupture of fenestra rotunda
 - (c) Endolymph getting into semicircular canals
 - (d) Fear of great height
- 25. Which of the following nerve supplies organ of corti

[RPMT 2002]

- (a) Auditory
- (b) Olfactory
- (c) Trochlear
- (d) Vagus
- **26.** The vibrations of the tympanic membrane are amplified approximately.....times in the oval window

[AMU (Med.) 2010]

(a) 5

(b) 20

(c) 40

- (d) 55
- 27. The opening in the nasopharynx that permits air pressure on both sides of tympanic membrane of the ear to be kept equal is [AIIMS 1992; CPMT 1992; JIPMER 2002]
 - (a) Oval window
- (b) Tube of cochlea
- (c) Auditory nerve
- (d) Eustachian tube

 In mammalian ear, a membranous structure which separate the scala vestibuli and scala media is

[NCERT; MP PMT 2003]

- (a) Basilar membrane
- (b) Reissner's membrane
- (c) Autolith membrane
- (d) Tectorial membrane
- The organ of Corti in rabbit is concerned with the sense of [CPMT 1993; RPMT 2001; AFMC 2010]

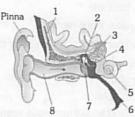

Or

Cochlea of mammalian internal ear is concerned with

- (a) Smell
- (b) Hearing
- (c) Taste
- (d) Equilibrium
- 30. Otoconium is found in
- [CBSE PMT 2000]
- (a) Perilymph
- (b) Haemolymph
- (c) Synovial fluid
- (d) Otolithic membrane
 [MP PMT 1999]
- Ear drum is known as
 (a) Tympanic membrane
- (b) Tensor tympani
- (c) Scala tympani
- (d) Scala vestibuli
- In the ear of man, the perilymph passes from middle to inner ear through [NCERT; CPMT 1999; JIPMER 2001]
 - (a) Foramen ovale
- (b) Fenestra ovalis
- (c) Fenestra rotundus
- (d) Tympanic membrane
- 33. Organ of corti is found in

[CPMT 1998; MHCET 2000; BVP 2001]

- (a) Internal ear
- (b) External ear
- (c) Both (a) and (b)
- (d) None of these
- **34.** See the following diagram. Identify 1 to 8
- [NCERT]

- (a) 1 Temporal bone, 2 Malleus, 3 Incus, 4 Cochlea,
 5 Stapes, 6 Eustachian tube, 7 Tympanic membrane, 8 External auditory canal
- (b) 1 Temporal bone, 2 Incus, 3 Malleus, 4 Stapes, 5
 Cochlea, 6 Eustachian tube, 7 Tympanic membrane, 8 External auditory canal
- (c) 1 Tympanic membrane, 2 Malleus, 3 Incus, 4 -Stapes, 5 - Cochlea, 6 - Eustachian tube, 7 - Temporal bone, 8 - External auditory canal
- (d) 1 Temporal bone, 2 Malleus, 3 Incus, 4 Stapes, 5
 Cochlea, 6 Eustachian tube, 7 Tympanic membrane, 8 External auditory canal

NCERT Exemplar Questions

- Chemicals which are released at the synaptic junction are called [NCERT]
 - (a) Hormones
- (b) Neurotransmitter
- (c) Cerebrospinal fluid
- (d) Lymph

- 2. Potential difference across resting membrane is negatively charged. This is due to differential distribution of the following ions [NCERT]
 - (a) Na+ and K+ ions
- (b) CO3++ and CI ions
- Ca⁺⁺ and Mg⁺⁺ ions
- (d) Ca+4 and CI- ions
- Resting membrane potential is maintained by 3.
 - (a) Hormones
- (b) Neurotransmitters
- (c) Ion pumps
- (d) None of the above
- The function of our visceral organs is controlled by

[NCERT; WB JEE 2016]

- (a) Sympathetic and somatic neural system
- (b) Sympathetic and para sympathetic neural system
- (c) Central and somatic nervous system
- (d) None of the above
- 5. Which of the following is not involved in Knee-jerk reflex

[NCERT]

- (a) Muscle spindle
- (b) Motor neuron
- (c) Brain
- (d) Inter neurons
- 6. An area in the brain which is associated with strong emotions is [NCERT]
 - (a) Cerebral cortex
- (b) Cerebellum
- (c) Limbic system
- (d) Medulla
- Human eyeball consists of three layers and it encloses

INCERTI

- (a) Lens, iris, optic nerve
- (b) Lens, aqueous humor and vitreous humour
- (c) Cornea, lens, iris
- (d) Cornea, lens, optic nerve
- Wax gland present in the ear canal is called [NCERT]
 - (a) Sweat gland
 - (b) Prostate gland
 - (c) Cowper's gland
 - (d) Sebaceous gland/ceruminous gland
- The part of internal ear responsible for hearing is [NCERT]
 - (a) Cochlea
- (b) Semicircular canal
- (c) Utriculus
- (d) Sacculus
- The organ of corti is a structure present in
- [NCERT]

- (a) External ear
- (b) Middle ear
- (c) Semi circular canal
- (d) Cochlea

Critical Thinking

Objective Questions

- 1. Which part of the brain is involved in loss of control when a [Kerala CET 2003] person drinks alcohol
 - (a) Cerebellum
- (b) Cerebrum
- (c) Medulla oblongata
- (d) Pons varoli
- In reflex action the reflex arc is formed by
- INCERTI
- (a) Brain spinal cord muscles
- (b) Receptor spinal cord muscles
- (c) Muscles receptor brain
- (d) Muscles spinal cord muscles

- How do parasympathetic neural signals affect the working of the heart [MP PMT 1996; CBSE PMT 2014]
 - (a) Both heart rate and cardiac output increase
 - (b) Heart rate decreases but cardiac output increases
 - (c) Reduce both heart rate and cardiac output
 - (d) Heart rate is increased without affecting the cardiac
- The accumulation of protein called amyloid β peptide in human brain causes [Kerala PMT 2006]
 - (a) Addison's disease
- (b) Huntington's disease
- (c) Alzheimer's disease
- (d) Motor-neuron disease
- (e) Parkinson's disease
- 5. The reflex arc which is made of two neurons is known as

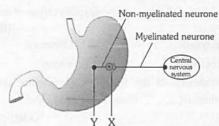

[WB JEE 2011]

- (a) Monosynaptic reflex arc (b) Disynaptic reflex arc
- (c) Polysynaptic reflex arc (d) Asynaptic reflex arc
- Match the entries in column I with those in column II and 6. choose the correct combination from the options given

Column I Column II A. Diencephalon 1. Cerebellum Medulla B Telencephalon C. Myelencephalon Amugdala D. Metencephalon 4. Thalamus

[Kerala PMT 2006]

- (a) A-4, B-3, C-1, D-2
- (b) A-3, B-4, C-1, D-2
- (c) A-4, B-3, C-2, D-1
- (d) A-1, B-2, C-3, D-4
- (e) A-4, B-1, C-2, D-3
- Suppose a person wears convex glasses for proper vision. Where you think the image of the object is formed in his eyes when he is not using the glasses
 - (a) On the blind spot
- (b) On the yellow spot
- (c) Behind the retina
- (d) In front of the retina
- The given diagram shows the parasympathetic innervation 8. of smooth muscle and glands of the stomach

Select the right option in which the chemical transmitters are released at the synapses X and Y are correctly identified

[NCERT]

- (a) X noradrenaline; Y calcium ions
- (b) X acetylcholine; Y noradrenaline
- (c) X acetylcholine; Y calcium ions
- (d) X acetylcholine; Y acetylcholine

UNIVERSAL BOOK DEPOT 1960

9. The ventricles of the brain are filled with

[DPMT 1993]

- (a) Cerebro-spinal fluid
- (b) Lymph
- (c) Blood
- (d) Amniotic fluid
- 10. In Myasthenia gravis acetylcholine

[AMU (Med.) 2010]

- (a) Receptors on motor end plate are reduced
 - (b) Secretion from nerve terminals is reduced
- (c) Esterase activity is inhibited
- (d) Secretion from nerve terminals is enhanced
- 11. Vagus (Pneumogastric) nerve is

[CBSE PMT 1992; BVP 1997, 2001; KCET 1998; Wardha 2005; WB JEE 2016]

- (a) Spinal nerve
- (b) Sympathetic nerve
- (c) X-cranial nerve
- (d) Parasympathetic nerve
- 12. Which one is the function of parasympathetic nervous system in mammals [CBSE PMT 1990]
 - (a) Acceleration of heart beat
 - (b) Constriction of pupil
 - (c) Stimulation of sweat glands
 - (d) Contraction of arrector pilli muscles
- 13. Which cranial nerve carries in excitation from the ear

[MP PMT 1994]

Or

The cranial nerve which brings impulses from the internal ear is [MP PMT 2013]

- (a) Optic
- (b) Auditory
- (c) Olfactory
- (d) Trigeminal
- 14. Which is a characteristic of a graded potential

[AMU (Med.) 2009]

- (a) The amplitude is always the same
- (b) The duration varies
- (c) Always followed by a refractory period
- (d) Is an all or none response
- 15. The centre for sense of smell in brain is

[MP PMT 1999, 2003; AFMC 2003, 05; MH CET 2004, 07]

- (a) Cerebellum
- (b) Cerebrum
- (c) Olfactory lobes
- (d) Midbrain
- 16. Brain depends on blood for the supply of

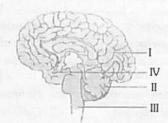

[CPMT 1999; RPMT 1999; JIPMER 2001]

- (a) Oxygen and ATP
- (b) Oxygen and electrolytes
- (c) Oxygen and glucose
- (d) ATP and glucose
- 17. The sound waves produce the vibrations in the endolymph, which in turn affects one of the following to produce the stumuli for hearing
 - (a) Basilar membrane
- (b) Tectorial membrane
- (c) Reissner's membrane
- (d) Cochlear duct
- 18. The venom of cobra affects the

[JIPMER 1994; BVP 2000; AFMC 2009; MP PMT 2013]

- (a) Digestive system
- (b) Circulatory system
- (c) Nervous system
- (d) Respiratory system
- 19. The jumping of action potential from node to node (of Ranvier) in a fibre is called [CPMT 1992]
 - (a) All or none principle
- (b) Threshold stimulus
- (c) Nodal conduction
- (d) Saltatory conduction

20. The given diagram is that of human brain

Which functions is performed by the part labelled III in the given diagram

- (a) Maintaining posture
- (b) Controlling learning
- (c) Regulation of heartbeat
- (d) Regulation of body temperature
- 21. Molecules that bear charged groups of opposite polarity are known as [DUMET 2010]
 - (a) Zwitterions
- (b) Cations
- (c) Anions
- (d) Negative ions
- 22. Synaptic fatigue is due to
 - (a) Exhaustion of neurotransmitter
 - (b) Release of more acetylcholine
 - (c) Release of more adrenaline
 - (d) None of these
- 23. A touch on the right hand stimulates neurons in

[Odisha JEE 2005]

- (a) Left somatic sensory area
- (b) Right somatic sensory area
- (c) Both (a) and (b)
- (d) None of these
- 24. Read the following statements and choose the correct option
 - A. Blood cells secrete fibres of structural proteins called collagen or elastin
 - B. Neuroglial cells protect and support the nephrons
 - C. Osteocytes are present in spaces called lacunae
 - Striated muscle fibres are bundled together in a parallel fashion
 - E. Biceps are involuntary and striated

[Kerala PMT 2012]

- (a) C and D alone are wrong
- (b) B and D alone are wrong
- (c) A and C alone are wrong
- (d) B and C alone are wrong
- (e) A, B, and E alone are wrong
- **25.** Small lesions on spinal tissue, slip disc in spinal column and micro cancer like tumour are detected by

[AMU (Med.) 2005; Kerala PMT 2009]

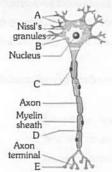

- (a) Magnetic resonance imaging method
- (b) Sonography method
- (c) Positron Emission Tomography method
- (d) X-ray Radiography method

- 26. Manifestation of increase in the blood pressure of a person is [J & K CET 2005]
 - (a) Hypertension
- (b) Atherosclerosis
- (c) Arteriosclerosis
- (d) None of these
- Mouth becomes watery when we look on the delicious food is due to [J & K CET 2005]
 - (a) Olfactory response
- (b) Hormonal response
- (c) Neural response
- (d) Optic response
- 28. An action potential in the nerve fibre is produced when positive and negative charges on the outside and the inside of the axon membrane are reversed, because [AIIMS 2007]
 - (a) More potassium ions enter the axon as compared to sodium ions leaving it
 - (b) More sodium ions enter the axon as compared to potassium ions leaving it
 - (c) All potassium ions leave the axon
 - (d) All sodium ions enter the axon
- Taste buds detect the substance only when the substance is
 - (a) Solid
- (b) Semisolid
- (c) Semiliquid
- (d) Liquid
- 30. 'Adaptation' of eyes in dark is due to
- [BHU 2005]
- (a) Depletion of vision pigment in rod
- (b) Depletion of vision pigment in cones
- (c) Repletion of vision pigment in rods
- (d) Repletion of vision pigment in cones
- In mammals, sound wave receptors are 31. [MP PMT 1998]
 - (a) Ears
- (b) Eyes
- (c) Skin
- (d) Hair
- 32. Organs of Ruffini are receptors of

[BHU 1995; AMU (Med.) 2006; MP PMT 2007]

- (a) Heat
- (b) Cold
- (c) Pressure
- (d) Touch
- 33. The given figure show the structure of neuron. Identify A, B, C, D and E [NCERT]

	A	В	C	D	E
(a)	Dendrites	Cyton or cell body	Nerve cell	Node of Ranvier	Synaptic knob
(b)	Dendrites	Nerve cell	Schwann cell	Node of Ranvier	Synaptic knob
(c)	(c) Dendrites Cyton or cell body		Schwann cell	Node of Ranvier	Synaptic knob
(d)	Nerve fibre	Cyton or cell body	Schwann cell	Node of Ranvier	Synaptic knob

- When the intensity of light is low during night, the light is [MP PMT 1996, 2002, 11] detected by
 - (a) Rods
- (b) Cones
- (c) Lens
- (d) Both rods and cones
- Fovea centralis of retina perceives (a) Diffused light
 - [MP PMT 1992] (b) Dim light
 - (c) Coloured light
- (d) Coloured and dim light
- 36. Eye is said to be near-sighted when a
- [MP PMT 1992]
 - (a) Near object is focussed in front of the retina
 - (b) Distant object is focussed in front of retina
 - (c) Near object is focussed behind the retina
 - (d) Distant object is focussed behind the retina
- 37. If an organism has more rods it will
- [BVP 2004]

- (a) Active during day
- (b) Possess colour vision
- (c) Active during night
- (d) Both 'a' and 'c' are possible
- 38. The pupil becomes bigger to allow more light during dark by
 - (a) Contraction of radial muscles of the iris
 - (b) Relaxation of radial muscles of the iris
 - (c) Contraction of circular muscles of the iris
 - (d) Contraction of suspensory ligaments
- 39. The part of an eye which acts like a diaphragm of a photographic camera is
 - (a) Pupil
- (b) Iris
- (c) Lens
- (d) Cornea
- The defective condition of accommodation of the eye in which distant objects are seen distinctly but near objects are indistinct is [AFMC 1994]
 - (a) Astigmatism
- (b) Presbyopia
- (c) Myopia
- (d) Hypermetropia
- The point in eye of mammals from which optic nerves and blood vessels leaves the eye ball is [NCERT; AFMC 2004]
 - (a) Yellow spot
- (b) Blind spot
- (c) Pars optica
- (d) None of these
- 42. Fishes have very poor sense organs for
- [BHU 2000]
 - (a) Detecting odours
 - (b) Light perception
 - (c) Sound perception
 - (d) Detecting vibrations in water
- The eyes of cat, cow, buffalo and some nocturnal animals shine in night. It is due to the presence of tapetum lucidum between the choroid and retina. This shining is due to the presence of a pigment made of
 - (a) Cytocine
- (b) Uracil
- (c) Guanine
- (d) Thiamine
- 44. In which direction cristae of rabbit ear helps in maintaining [RPMT 2006]
 - (a) Circular position of longitudinal axis of semi circular canals
 - (b) Transverse position of longitudinal axis of semi circular canals
 - (c) Parallel to longitudinal axis of semi circular canals
 - (d) All of the above

UNIVERSAL BOOK DEPOT 1960

- 45. In cataract [RPMT 2001; JIPMER 2002]

 (a) Due to ageing or some infection eye lens becomes opaque

 (b) Flasticity of eye lens is loct
 - (b) Elasticity of eye lens is lost
 - (c) There is irregular curvature of lens
 - (d) Eye ball becomes shorter
- **46.** How many eye muscles are present which control all types of eye movement
 - (a) 3

(b) 4

(c) 5

- (d) 6
- 47. Bowman's glands are located in the

[MP PMT 1998; CBSE PMT 2007]

- (a) Proximal end of uriniferous tubules
- (b) Anterior pituitary
- (c) Female reproductive system of cockroach
- (d) Olfactory epithelium of our nose
- 48. What is the correct sequence of the parts of the eye that the light rays cross in reaching the retina [CMC Vellore 1993]
 - (a) Pupil \rightarrow cornea \rightarrow aqueous humour \rightarrow lens \rightarrow vitreous humour
 - (b) Lens \rightarrow cornea \rightarrow aqueous humour \rightarrow vitreous humour \rightarrow pupil
 - (c) Aqueous humour \rightarrow vitreous humour \rightarrow cornea \rightarrow pupil \rightarrow lens
 - (d) Cornea \rightarrow aqueous humour \rightarrow pupil \rightarrow lens \rightarrow vitreous humour
- 49. The cornea is a very important component of the human eye. The main function of the cornea is to [AIIMS 2010]
 - (a) Bend the light before it reaches the lens
 - (b) Provide structural support to the eye
 - (c) Contain a concentrated amount of cone cells in the correct orientation
 - (d) Change the shape of the lens to enable the image to be focused on the retina

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below :

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- 1. Assertion : The imbalance in concentration of Na^+ , K^+ and proteins generates resting potential.
 - Reason : To maintain the unequal distribution of Na^+ & K^+ , the neurons use electrical energy. [AIIMS 2002, 09]

- 2. Assertion : Rabies is acute infectious disease of warm blooded mammals characterized by involvement of central nervous system
 - resulting in paralysis and finally death.

 Reason: This is caused due to neurotropic filterable bacteria in saliva of rabid animals.

[AIIMS 2000]

- Assertion : Transmission of the nerve impulse across a synapse is accomplished by neurotransmitters.
 - Reason : Transmission across a synapse usually requires neurotransmitters because there is small space i.e. synaptic cleft, that separates one neuron from another.

[AIIMS 1999]

- 4. Assertion : Medulla oblongata causes reflex actions like vomiting, coughing and sneezing.
 - Reason : It has many nerve cells which control autonomic reflexes. [AIIMS 1994]
- **5.** Assertion : Anterior lobe of pituitary is attached to hypothalamus by a vein.
 - Reason : This attachment is done through a portal vein. [AIIMS 1993]
- **6.** Assertion : After hearing a sound, nerve impulse passes from neurons to the brain.
 - Reason : The neurons which pass nerve impulses from the body organ to the brain is called afferent neuron.
- 7. Assertion : Cerebrospinal fluid is present throughout the central nervous system.
 - Reason : CSF has no such function.
- 8. Assertion : All motor neurons are efferent neurons.
 - Reason : Motor neurons conduct nerve impulses from the spinal cord to the brain.
- Assertion : Some areas of the brain and spinal cord look white.
 - Reason : This is because cell bodies of neurons are situated in those areas.
- Assertion : In man, only peripheral nervous system is present.
 - Reason : The peripheral nervous system includes nerves coursing between the central nervous system and different parts of the body.
- **11.** Assertion : Spinal cord has a column of both grey and white matter.
- Reason : Grey matter forms the central spinal canal.
- 12. Assertion : Vitamin A deficiency produces night blindness.
 - Reason : Photosensitive pigment rhodopsin is synthesised from vitamin A.

 Assertion : Tongue is a gustatoreceptor
- 13. Assertion : Tongue is a gustatoreceptor.

 Reason : Receptors for gustatory sensations are located in the taste bud. [AIIMS 2000]

UNIVERSAL BOOK DEPOT 1960

994 Neural Control and Coordination

14. Assertion : Circular smooth muscles of iris contract

when bright light falls on the eye.

Reason : Pupil gets constricted by the contraction of

circular smooth muscles of iris.

15. Assertion : Sparrows possess poor night vision.

Reason : Sparrows eyes are made up of ommatidia.

16. Assertion : The eye is said to have power of

accomodation.

Reason : Ciliary muscles alters the shape of the lens

for near or far vision during accomodation.

17. Assertion: Nerve fibre can become excited through

touch, smell, pressure and chemical changes and there is a change in polarity.

Reason : It is called active potential [GUJCET 2015]

Answers and Solutions

Development of central nervous system in human

- (c) Corpus callosum is a thick whitish band of semicircular nerve fibres interconnecting two cerebral hemispheres (found only in mammals).
- (a) Largest cell in the body is neuron. Certain neurons may almost equal the length of body itself.
- (b) Optic nerve is sensory, therefore it originates from retina and is distributed in mid-brain.
- (a) Sympathetic nervous system increases defence system of body against adverse conditions. It is active in stress condition. Such as pain fear and anger.
- 8. (d) Autonomic nervous system regulates and coordinates involuntary activities like heart beating, homeostasis, body temperature, breathing, gut peristalsis and secretion of glands.

Parts of nervous system

- 1. (c) VIII, the auditory cranial nerve.
- (d) A mammal, from whose brain cerebrum is removed loses all responses that depend upon consciousness and memory.

- (d) Hind brain has two distinct part (i) metencephalon (medulla oblongata) (ii) myelencephalon (cerebellum), transverse band of white matter called pons varoli.
- (a) Cerebellum is responsible for co-ordination of body movements.
- 6. (d) Reflex action is an immediate involuntary response to a stimulus with out the intervention of brain, controlled by spinal cord of central nervous system.
- (b) Man has 31 pairs of spinal nerves while rabbit has 37 pairs.
- 8. (b) III, IV and VI cranial nerves.
- 9. (a) The smallest cranial nerve is trochlear in human beings.
- 10. (a) The post-ganglionic nerve fibres of sympathetic nervous system are adrenergic i.e., they release the neurotransmitter nor-adrenaline at their termination. The sympathetic nerves stimulate the adrenal glands to secrete adrenaline.

The post-ganglionic para-sympathatic fibres are cholinergic i.e., they release a chemical substance acetyl choline, a neurotransmitter, at their endings for the transmission of nerve impulses.

- (a) Ependymal cells are columnar cells that have ciliated surface. They support the central nervous system and also nutritive in function.
- (a) Sympathatic nerves are composed of efferent fibres derived from the thoracic and lumbar regions of the spinal cord.
- 15. (d) Accessory nerves arise from the side of medulla oblongata and supply to the muscles of the pharynx, larynx neck and shoulder. They are motor nerves.
- 16. (a) Between paracoel and diocoel.
- 20. (a) Arbor vitae is a branched tree like structure composed of white matter in cerebellum.. It is also presumed to be the seat of soul.
- 22. (b) Abducens is motor nerve which arise from the ventral surface of medulla oblongata these nerve helps in rotation of eye balls. The optic are sensory nerve. Ophthalmic and palatinus are mixed nerve.
- 31. (a) Parasympathetic nervous system stimulates the peristaltic movement of digestive tract, contracts the wall of urinary bladder and reduces the diameter of the pupil by contracting the iris.
- **32.** (a) It coordinates the activity of both the cerebral hemispheres.
- (d) Hypothalamus contains higher nerve centres for temperature regulation, hunger, thirst and emotional reactions.
- (c) Hypothalamus is the floor of diencephalon which is the part of fore brain. It has thermoregulatory centre, hunger and thirst centre.
- 38. (e) Crura cerebrae are thickened ventral portions of the mid-brain of a vertebrate consisting of nervous tracts linking the thalamencephalon with the hind-brain.

- 39. (a) Reflexes are classified as the spinal reflexes and the cranial reflexes. The former are so called because their basic neural path leads through spinal nerves and spinal cord. Reflexes at the spinal level have the purpose of removing the animal from harmful stimuli.
- (a) Parkinson's disease or paralysis agitans is a defect of brain.
- 41. (c) The primary acoustic centre is in the temporal lobe of cerebral hemispheres.
- 42. (b) Occipital lobe is the centre for sight as the greater part of the visual area lies in it.
- 43. (c) All spinal nerves are sensory and motor both (mixed).
- 44. (d) Central nervous system comprises brain and spinal cord both are surrounded by the three protective membranes these are duramater, arachnoid mater – piamater.
- 45. (a) Cerebellum primary functions is to maintain posture, orientation and equilibrium of body by co-ordinating and regulating tone and contraction of voluntary muscles, mainly according to the commands of cerebellum.
- 48. (a) The motor cranial nerves are III, IV, VI, XI and XII.
- 49. (c) The thick wall of spinal cord consists of an inner zone of grey matter and a peripheral zone of white matter.
- (a) Occulomotor nerve has occulomotor nucleus and Edinger-Westphal nucleus.
- 55. (d) The upper or superior surface of the "mid brain" has two pairs of rounded protrusions collectively called the corpora quadrigemina one pair is called superior colliculi and the other pair is called inferior colliculi. In frog, corpora quadrigemina are the optic lobes. The superior colliculi are concerned with sense of sight. However inferior colliculi are concerned with hearing.
- 56. (a) Reflexes developed by training and learning are called conditioned or acquired reflexes for example after proper learning, we can perform dancing, cycling, swimming, singing, playing etc. simply by reflexes.
- **57.** (d) Autonomic nervous system controls involuntary functions of the visceral organs.
- 59. (a) Conditional reflexes were first demonstrated by the Russian scientist, Pavlov in dogs.
- 61. (b) Nerve that connect only receptor organs to the CNS are purely sensory or afferent nerve because these contain only sensory nerve fibres.
- **62.** (a) Reflex is the spontaneous automatic mechanical response to a stimulus without animals' s will.
- 63. (d) Ventricles I and II of cerebral hemispheres are called as paracoels or lateral ventricles. Ventricle III is known as diocoel. Ventricle IV is the metacoel.

- 65. (c) Vagus nerve has five branches -
 - (i) Superior laryngeal nerve
 - (ii) Recurrent laryngeal nerve
 - (iii) Cardiac nerve
 - (iv) Pneumogastric nerve
 - (v) Depresser nerve
- 66. (d) Broca's area is the speech centre which controls the movement of lips, tongue, larynx, pharynx etc.
- 67. (a) Brain and spinal cord are surrounded by three meninges – duramater and piamater, arachnoid in mammals.
- 68. (c) It is found at the roof of diencephalon. The anterior part of the diencephalon is vascular and folded to form the anterior choroid plexus.
- 69. (b) Nerve cell are highly specialized cell which have no power of division because they do not have centrosome.
- 70. (a) This is also sensory. It brings sensory impulse from the skin of upper lip upper jaw, nasal mucosa and lower eyelids.
- 72 (a) The medulla oblongata passes out through the foramen magnum and continues into spinal cord, which is contained in the neural canal of vertebral column.
- 75. (a) The cavity of the hind brain, called fourth ventricle, is rhomboidal and limited to the anterior part of medulla oblongata.
- 77. (c) The cavities (= lateral ventricles or paracoels) of the cerebral hemispheres remain separate in frontal lobes. In temporal lobes these join together and communicate behind, by a common foramen of monro, with the diocoel (3rd ventricle) cavity of diencephalon.
- 78. (c) Wernicke's area is responsible for understanding speech.
- 79. (d) Neurons the specialized all of nervous system. In nervous system has no power of regeneration.
- 80. (d) Reflex arc is the basic functional unit of nervous system. The entire impulse circuit of a reflex response. receptors → CNS → effector
- **81.** (c) Cervical 8 pairs, thoracic 12 pairs, lumbar 7 pairs, sacral 4 pairs, caudal 6 pairs *i.e.* total 37 pairs.
- **82.** (c) Trigeminal nerve is the fifth cranial nerve of frog. It arises from the antero-lateral sides of medulla oblongata.
- 83. (a) A band of white nerve fibres, the corpus callosum connects the two cerebral hemispheres together in mammalian brain.
- 85. (a) In which sympathetic nerve fibres are included.
- **88.** (a) Abducens is the sixth number of motor cranial nerve which regulate the movement of eye ball.

UNIVERSAL BOOK DEPOT 1960

- 89. (d) In human beings, the 12 pairs of cranial nerves and 31 pairs of spinal nerves and 12 pairs of Ribs are present.
- 94. (c) I, II and VIII i.e. olfactory, optic and auditory.
- 95. (c) Ventricle III is known as diocoel is a small cavity of diencephalon.
- 97. (c) X-cranial nerve controls the visceral sensation, and visceral movements (peristalsis, sound production, respiratory movements, heart beat)
- 99. (b) Ivan Pavlov of Russia (1906), on the basis of experiments with dogs showed that conditioned reflex affects behaviour.
- 101. (a) The nerve fibres of ventral root carry motor impulses away from the spinal cord.
- **102.** (c) Sensory nerve fibres are located in the dorsal root ganglion.
- 104. (b) The medullary sheath, or myelin sheath is continuous around the nerve fibres in the CNS but in the nerve fibres of PNS it is absent.
- 105. (d) Autonomic response obviously occur very fast we do not even feel the stimulus. Thus reflex reaction protect the body against injurious effects of sudden stimuli.
- 106. (d) Cerebrum (cerebral hemisphere) is centre of thinking, will power, reasoning and memory, experience and learning knowledge and articulate speech.
- 108. (b) Lateral ventricles are cavities of cerebrum.
- 109. (d) Medulla oblongata contains centre for the autonomic reflex control of respiration, heart beat and these centre are called vital centres because damage to them is usually total.
- 112. (a) Myelinated or medullated nerve fibre (Axon) is surrounded by inner thick medullary sheath of fatty matterial called myelin.
- 114. (a) The thin roof of III ventricle (diocoel) is called epithalamus. The anterior part of epithalamus contains a highly coiled bunch of blood capillaries called anterior Choroid plexus. The dorsal surface of metacoel also contains highly coiled bunch of blood capillaries called post choroid plexus.
- 115. (a) Axon is a single long process of uniform thickness. It contain neurofibrils and neurotubules but lack nissle's granules, golgi complex ribosomes etc.
- **116.** (a) Broca's area is part of frontal lobe of cerebrum is related with speech.
- 117. (b) Sympathetic nervous system increases the (i) rate and force of heart beat, (ii) constricts most blood vessels, (iii) raises the arterial blood pressure, (iv) dilates the pupil, (v) slows down peristaltic movements, (vi) and relax the urinary bladder.

- 118. (c) 3rd, 6th, 11th cranial nerve are occulomotor, abducens and spinal accessory respectively. All of these are motor nerve.
- 119. (b) Foramen of monro is the space in the brain of frog and rabbit which joins lateral ventricle of diocoel to the III ventricle of brain.
- 120. (a) Subarachnoid space is found between arachnoidmater and piamater. It contains CSF. It is absent in frog but present in mammals.
- 122. (c) In myogenic heart, heart beat is continuous even after the nerve supply is cut.
- 123. (b) The cranial nerve III, IV and VI are motor nerve and control eye ball movement known as III occulomotor IV trochlear and VI Abducens nerve.
- 124. (a) Unconditioned reflexes are inborn, inherited and species specific and stable and controlled by spinal cord.
 - Conditioned reflexes are acquired by learning and experiences and controlled by cerebral cortex of brain.
- 125. (a) Nodes of Ranvier are uncovered part of an axon.
- **126.** (c) Cerebrum is the part of fore-brain, which develops from embryonic prosencephalon.
- 127. (ad) Parasympathetic nervous system includes four cranial nerves – III [Occulomotor] VII [Facial], IX [Glossopharyngeal] and X [Vagus].

Biochemical aspect of nervous physiology

- 4. (c) Nerve impulses are transmitted from axon to dendron with the help of acetylcholine and adrenaline called neurotransmitters, produced by the secretory vesicles of the synaptic knob.
- (a) The movement of Na⁺ into the axoplasm leads to the depolarization of nerve.
- (a) Arrival of an impulse at the synaptic knob causes the acetylcholine to be discharged into synaptic cleft.
- 20. (b) (a) During resting membrane potential, Na⁺ ions are more on the outer side of membrane due to Na⁺ K⁺ ion pumps; (b) Action potential lasts only for very short time and Na⁺ ions are more on the inner side of membrane; (c) During depolarization, Na⁺ ion channels open leading to influx of Na⁺ developing positive charge on inner side of plasma membrane; (d) During repolarization, Na⁺ ion channel get closed and K⁺ ion channels open leading to efflux of K⁺ moving it outerside of membrane.
- 23. (d) Efflux of K⁺ causes repolarization. Therefore it is the movement of K⁺ that maintains the depolarized state.

- 26. (a) In poliomyelitis, anterior horn cells of spinal cord are destroyed which result in loss of motor activities of limbs.
- 28. (c) At the end of repolarization, a difference in concentration of positive ions on two sides of plasma membrane is generated leading to ionic imbalance. During repolarization, K⁺ ion channels open up and K⁺ ions move out of the plasma membrane.
- **29.** (b) Nerve impulse carry through afferent nerve fibres from receptors to central nervous system.
- 30. (d) It is a strong insulating layer which prevents almost all flow of ions through the axonic surface and thus prevent the leakage of impulse.
- **34.** (a) On medullated nerve fibres speed of nerve impulse is about 20 times faster than on non-medullated nerve fibres.
- 36. (a) In a synapse, the transmitting cell is called the presynaptic cell and the gap in between is called a synaptic cleft. Synaptic vesicles are found in presynaptic neuron. They contain neurotransmitters which on stimulation are released into the synaptic cleft and then these chemicals combine with the receptors on the postsynaptic neuron causing depolarization.
- (d) Na⁺ enters in the axoplasm leading to depolarization of the nerve.
- **39.** (d) Nerve impulse is a self propagating wave of depolarization and repolarization.
- 42. (b) Sub-arachnoid space found between the arachnoid membrane and pia-mater, which is filled with cerebrospinal fluid.
- 43. (d) Animals have two system of co-ordination i.e., nervous system and endocrine system. Neurones are the basic structural and functional units of the nervous system which spread through out the organism forming a complex communication network. Endocrine system release hormone for intercellular communication.
- 44. (d) Gamma amino butyric acid (GABA) and glycine are inhibitory transmitters. An inhibitory transmitter is one that is released by an inhibitory neuron. It can inhibit impulse at synapse.
- 45. (b) Transmission of nerve impulse, across a synapse is accomplished by neurotransmitters because of synapse. It separates one neuron from other.
- 47. (c) Parkinson's disease in characterised by tremors and progressive rigidity of limbs caused by a degeneration of brain neurons and a neurotransmitter called dopamine.
- 48. (d) Autonomic nervous system regulates and coordinates involuntary activities like heart beating, homeostasis, body temperature, breathing, gut peristalsis and secretion of glands.

- 49. (d) The post ganglionic parasympathetic fibres release a chemical substance acetylcholine.
- **51.** (d) Hypothalamus contains higher nerve centre for temperature regulation, hunger, thirst and osmoregulation.
- 56. (a) When a neuron is in resting state i.e., not conducting any impulse, the axonal membrane is comparatively more permeable to K⁺ ions and nearly impermeable to Na+ ions.
- **62.** (c) Neuromuscular junction is the junction between motor neuron and muscle fibre.
- 63. (abd) Tyrosine amino acid is required for synthesis of dopamine. Adrenaline is formed by methylation of noradrenaline using Phenylethanolamine Nmethyltransferase.
- 65. (a) In CNS, myelin sheath is formed by oligodendrocytes, while in PNS, it is formed by Schwann cells

Different types of Receptors

- (b) Pacinian corpuscles are tactile receptors occur in deeper layer of skin in neck, arms, nipples, external genital, palms and soles. These receive stimulus of strong pressure and vibrations of sustained contacts.
- (b) Rod is a kind of light-sensitive nerve cell present in vertebrate retina. Rods do not discriminate fine details or colour differences.
- 3. (c) Neuromast organs are little groups of receptor and supporting ectodermal cells found in the lateral line canals. Neuromast organs are current receptor or rheoreceptor and can perceive vibration of very low frequency.
- (a) Jacobson's organ (vomeronasal organ) is concerned with smell.
- 5. (c) Jacobson's organs are present in the anterior part of nasal cavity which is well developed in snakes and lizards while vestigeal organ in man.
- (b) A small, bipectinate chemoreceptor called osphradium is present in the mantle cavity of Pila and is sensible to chemical stimulus.
- 8. (d) Meissner corpuscles are specialised sense organs situated immediately beneath epidermis in the skin. These respond to touch and pressure.
- (c) Long stiff tactile hairs, the vibrissae (pili tactiles) project from the side of mouth, external nares and above the eye.
- (d) Proprioceptors are situated internally, and detect changes in the internal environment of body.
- 14. (d) Bats produce subsonic sound which are received by ear after being reflected by the surrounding objects. The time taken by the echo indicates the distance of object to bat.
- 15. (b) Proprioceptor are sensory nerve ending located deep with muscles, tendons, joints and vestibular apparatus that respond to stimuli originating from within the body regarding movement and spatial position.

UNIVERSAL BOOK DEPOT 1960

Eye

- (c) Iris is a pigmented disc like part which is found between cornea and lens. Iris consist of circular sphincter and radial dilators muscles which controls the light entering into the eye.
- (b) Choroid is the middle pigmented and vascular layer in the wall of the eye of a vertebrate between retina and sclerotic coat.
- (c) Rhodopsin is a visual purple pigment (formed by vitamin A and opsin protein) sensitive to dimlight. It helps in twilight vision during night.
- (d) Fovea is present at centre of macula lutea, which is centre of highest resolution, has only cones
- 6. (d) In glaucoma, there is over production of vitreous humour which increases the pressure in the eye and this crushes the delicate cells of the retina, causing blindness.
- (a) Blind spot in the eye is the place where neither rods nor cones present.
- (a) Vitamin A is the precursor of the purplish red pigment rhodopsin contained in the rods (photoreceptor) cells of human eye.
- **14.** (b) Iodopsin is photosensitive visual pigment found in cones of retina.
- 20. (b) The muscles associated with the iris regulate the amount of light entering the eyeball by varying the size of the pupil.
- 28. (a) The eye lens is made of transparent proteins called crystallins. The proteins are arranged in approximately 20,000 thin concentric layers. The average concentration of lens protein is about twice than that of other intracellular proteins & is thought to play a structural role in the lens.
- 31. (a) Unstriped or non striated or visceral or smooth or involuntary muscles are found in iris of eye, oesophagus, stomach, intestine lungs, urinogenital tract, urinary bladder and blood vessels.
- 35. (c) Each eye of cockroach is a compound structure of about 2000 ommatidia which are the visual units of photoreception.
- 36. (c) Myopia is near sightedness. In this defect, the light rays converge in front of retina causing a blurred image.
- **37.** (d) Owl is able to see at night but has poor day vision due to the presence of only rods in eyes.
- 40. (a) Glucoma develops due to increased intraocular tension as a result of blocking of canal of schlemm. The pressure in eye rises above the normal range of 15-20 mm of Hg since to aqueous humour is not drained out into the blood.
- (a) Central opening of iris is called pupil which controls the light entering into eye.
- 46. (d) The posterior part of the retina, which is just opposite to the lens is called area centralis or yellow spot, which contains only cones and has yellow pigment, the images are normally focussed on this area.

- 47. (c) Fovea centralis, a shallow depression at the middle of yellow spot (macula lutea), has only cone cells and is the place of most distinct vision.
- **52.** (d) Choroid in the middle layer of the eye which is highly vascular and covered with pigment cells.
- 53. (c) The cones are about 300 times less sensitive than the rods but even this allows colour vision in any light greater than dimlight.
- **58.** (b) Cone cells of retina are related to Photopic vision and also for perception of colours.

Ear

- (c) Pinna collects the sound vibrations and reflect them into external auditory canal. Besides this it also helps in localisation of sound source.
- (c) The scala vestibuli and scala tympani are filled up with perilymph and communicates with each other at the apex through a small opening helicotrema i.e., scala vestibuli is connected with scala tympani.
- 6. (c) Acoustic spots occur in the ampullae of semicircular ducts of internal ear or the membranous labyrinth. The wall of the membranous labyrinth of frog is lined with cubical epithelial cells. The epithelial lining, at certain places, is modified to form sensory patches called acoustic spots. There exists one in the utriculus, one in the sacculus, and one in the lagens. The sensory paths of ampullae are called cristae, while the other one are known as maculae.
- (a) These are called the *limits of audibility*. Actual value is 20 to 20000 cycles/sec.
- 10. (c) Perilymph is clear fluid present in the bony labyrinth of ear.
- (c) Three auditory ossicles in the middle ear are malleus incus and stapes.
- 20. (c) The crista and macula are the specific receptors of the vestibular apparatus responsible for maintenance of balance of the body and posture. These play no role in hearing.
- 23. (c) Hyomandibular is one pair of small cartilages or bone forming the dorsal ends of the hyoid arch of a vertebrate. Hyomendibular becomes modified to form an auditory ossicle the columella auris of amphibia, reptiles and birds and the stapes of mammals.
- (a) Cochlear branch of auditory nerve supplies the organ of corti.
- 27. (d) The function of eustachian tube is to equalize air pressure on both side (external and middle ear) of tympanic membrane.

- 28. (b) The scala vestibuli and scala media are separated by Reissner's membrane which makes up the roof or dorsal wall of the scala media.
- **29.** (b) Organ of Corti is the auditory sense organ within the spiral cochlea of mammalian ear.
- 30. (d) The otolithic membrane contains numerous minute, irregular particles called otoliths or otoconia which are made up of calcium carbonate and protein.
- (a) Ear drum is also known as tympaic membrane which separates middle ear from external ear.

Critical Thinking Questions

- (a) Because cerebellum is not concerned with conscious sensations. It maintains equilibrium.
- (b) Reflex arc is the pathway taken by nerve impulse generated at the receptors due to stimulus to reach the effector organ during reflex action.
- (c) Post-ganglionic fibers of parasympathetic nervous system secrete acetylcholine which decrease heart rate and cardiac output.
- 7. (c) Since the use of a convex lens decreases the focal length of the eye-lens, therefore in this case, the image is formed behind retina when lens is not used.
- 9. (a) The cerebrospinal fluid is secreted by anterior choroid plexus and posterior choroid plexus and is found inside the ventricles of the brain and central canal of the spinal cord.
- (cd) Vagus is 10th cranial nerve. It originates from the sides of medulla oblongata. In vertebrates it consists of sensory and motor fibres.
- 15. (c) Olfactory lobes are concerned with the sense of smell. The senses is very well developed in scoliodon, and dogs.
- 17. (b) The tectorial membrane overhangs the sensory hair in the scala media. Its properties are to determine the patterns of vibration of sound waves.
- (d) In white fibres (medullated) impulse jumps from node to node, it is called saltatory conduction.
- **22.** (a) Synaptic fatigue is a temporary suspension of impulse transmission in the region of synapses due to exhaustion of its neurotransmitter (acetylcholine).
- **31.** (a) Otoconia helps in balancing the body, during the change of posture when the body is imbalanced and tilted onto one side the otoconia touch the sterocilia and bend it causing the generation of nerve impulse.
- **32.** (a) End organ of Ruffini are external receptors of heat present in skin.

- 34. (a) Rods are sensitive to dimlight.
- 36. (b) Myopia or near sightedness is related abnormalities of eye in which eye ball becomes elongated, increasing the horizontal axis of eye. The image is formed before retina instead of upon it.
- 39. (b) The iris of eye can be compared with the diaphragm of a camera as it regulates the amounts of light entering in eye by constricting or dilating the pupil.
- 43. (c) Many nocturnal mammals also have tapetum lucidum which contain light reflecting crystals of guanine.
- 44. (b) The cristae of rabbit ear helps in maintaining balance in transverse position of longitudinal axis of semicircular canals.
- 45. (a) Cataract defect develops when lens becomes opaque and looses its flexibility, its density increases and it acquires amber colour.
- 46. (d) Eye can be moved by 6 extrinsic ocular muscles attached to its posterior wall. Two are external and internal oblique muscle while the other four are rectus muscles.
- 49. (a) Cornea is a transparent layer of tissue, continuous with the sclerotic that forms the front part of the vertebrate eye over the iris and lens. The cornea refracts light entering the eye onto the lens, thus assisting in the focusing of images onto the retina.

Assertion and Reason

- (c) To maintain the unequal distribution of Na⁺ and K⁺ ion, the nerves uses chemical energy in form of ATP to actively transport Na⁺ ion out of cell and more K⁺ inside the cell.
- (c) Rabies is an overwhelming encephalomyelitis and includes severe headache and high fever with excitement and depression. This disease occurs by a virus called Rhabdovirus.
- (a) Neurotransmitters need to transmit the nerve impulses through synaptic cleft which is a small part at junction of two neuron.
- (a) Medulla oblongata consists of accumulation of nerve cells act as vital centres of many autonomic reflexes like vomiting, coughing and sneezing.
- (b) Anterior lobe of pituitary is called Pars distalis. It is attached to hypothalamus by hypophyseal portal vein. This portal vein called hypothalamo-hypophyseal portal vein.
- 6. (b) Activity of sense organs is related with two types of neurons (afferent and efferent). The neurons, which pass nerve impulses from the body organ to the brain, is called afferent neuron. The neurons, which pass nerve impulses from the brain to the body organs, are called efferent neurons.

- (c) An extracellular fluid, called cerebrospinal fluid is present throughout the central nervous system. It affords some protection to central nervous system from injury and shock.
- (c) The neurons and nerve fibres which conduct nerve impulse from the Central Nervous System (CNS) to the peripheral organs and tissues are called efferent neurons and efferent nerve fibres respectively. Some of the neurons and nerve fibres conduct nerve impulses to the muscles and gland to stimulate or inhibit their activities. Many of these nerve fibres cause movements of muscles. So, such neurons and nerve fires are known as motor neurons and motor nerve fibres, respectively. The motor nerve fibres are the axons of motor neurons. All motor neurons are efferent neurons, because they conduct impulses from the CNS to the peripheral tissues viz, muscles and gland. The nerve fibres which reach nerve impulses to the eye muscles to control their movements are motor fibres; so also are the fibres carrying impulses to the salivary glands and controlling their secretion.

The nerve impulses are conducted from the spinal cord to the brain by ascending nerve tracts which are the bundles of nerve fibres ascending along the white matter of the spinal cord.

- 9. (c) The brain and the spinal cord constitute the central nervous system. The areas of the CNS where the cell bodies of the neurons are situated, look grey and constitute the grey matter. Other areas look white and constitute the white matter of the CNS. The white matter contains only nerve fibres cruising from or to the nerve cells in the grey matter. It looks white due to the presence of myelin around the myelinated fibres. In most parts of the brain, the grey matter containing the nerve cells is situated on the surface while the white matter made of fibres is located deep inside the brain; but in the spinal cord, the grey matter is internal and white matter occurs outside.
- 10. (e) The nervous system of human comprises of Central Nervous System – comprises of brain and spinal cord. Peripheral Nervous System – comprises of nerves present between brain and body parts.
- 11. (b) The spinal cord extends downwards from the brain stem. The grey matter from a column running along the central part of the spinal canal (= neurocoel, lined with ciliated ependymal epithelium), containing the cerebrospinal fluid, running along the central part of the grey matter. Grey matter is composed of nerve cells, bodies, dendrites and synapses. The white matter forms an outer column surrounding the grey matter at its centre.
- 12. (a) Our eyes are the sense organs for vision. The light sensitive inner layer of eyeball called retina contain photoreceptors viz. rod and cone cells which convert the energy of specific wavelengths of light into action potentials of nerve fibres. Rods are sensitive even to dim light and consequently enable to see in dim light and at night. They contain a purple coloured photosensitive pigment, called rhodopsin. Rhodopsin consists of the protein scotopsin and retinene, a derivative of vitamin A which is required for proper vision and is required for the regeneration of rhodopsin after it has been exposed to light.

- 13. (a) Tongue is also called as gustatoreceptor and it is a receptor for taste. The receptor for gustatory sensation are loated in taste buds on tongue.
- 14. (b) The wall of each eyeball is made up of three concentric layer-sclerotic, choroid and retina. The choroid is a highly vascular pigmented layer separating the sclerotic from the inner layer of the eyeball. It is connected in front to a thick structure called ciliary body.

 Iris is a pigmented, muscular, opaque diaphragm which extends from the ciliary body in front of a biconvex transparent lens. Iris has a small central aperture called pupil. Light passing through the cornea enters through the pupil to fall on the lens behind it. The iris has two sets of smooth muscles arranged circularly and radially around the pupil. The pupil gets

constricted by the contraction of circular muscles to

reduce the amount of light falling on the lens. On the

contrary, the pupil gets dilated by the contraction of

radial muscles to increase the amount of light falling

on the lens.

15. (c) The light sensitive inner layer of eyeball called retina contain photoreceptors viz. rod and cone cells which convert the energy of specific wavelengths of light into action potentials of nerve fibres. Cone cells are sensitive to bright light only. So, they help to see in daylight or in a brightly illuminated room by electric lamps. Rod cells are sensitive even to dim light and consequently help to see in dim light and at night. Animals, like sparrows, which are active only in day time, have mostly cone cells in their retina and therefore they possess poor night vision.

Ommatidia are the elongated tube like units of a compound eye present in higher invertebrates like prawns, crabs and insects. Ommatidia are crowded over a spherical surface. Each focusses the light from a small area of the object so that a mosaic of a large number of images of the adjacent areas of the object are formed by numerous ommatidia. A fusion of these images may produce a composite blurred image of the object.

16. (b) The choroid is the middle layer of eyeball which is connected in front to a thick structure called ciliary body. Thread like suspensory ligaments extend from the ciliary body and get attached to a biconvex, transparent elastic Lens. For proper vision, light rays from a visual object must be focussed sharply and precisely on the retina. In the resting eye, the ciliary muscles remain relaxed, keeping the suspensory ligaments stoutly stretched which flattens the elastic lens to reduce its curvature.

The lens in this resting eye focusses parallel rays from distant objects (more than 6 m away) on the retina. But to increase the power of the lens for focussing divergent rays form near object on the retina, a reflex called accomodation is needed. The eye has got the property to form images of both near and far objects on the retina by changing the convexity of the lens. This is known as the power of accomodation.

Chemical Co-ordination and Integration

Endocrine system is formed of all endocrine glands of body. Though different endocrine glands are different in embryonic origin and are isolated from one another but these interact with one another so collectively form an endocrine system. Endocrine system along with nervous system, controls and coordinates the body functions and maintains a homeostasis. So both collectively form neuro-endocrine system. The study of these two systems is called neuro-endocrinology.

Glands of body: Animals have three types of glands.

- (i) **Exocrine gland (Gr.,** ex = out + krinein = to secrete): These glands have ducts for discharging their secretions. Therefore, they are called as duct glands. ex Liver, Sweat gland, Sebaceous gland, Gastric glands and some intestinal glands.
- (ii) Endocrine glands (Gr., endo = within + krinein = to secrete): These glands lack ducts and pass secretions into the surrounding blood directly. Therefore they are called as ductless glands. ex Thyroid, parathyroid, adrenal, pituitary, pineal body and thymus.
- (iii) Heterocrine glands: These glands consist of both exocrine and endocrine tissue. The exocrine discharge its secretion by a duct and the endocrine tissue discharges its secretion into the blood. Pancreas and gonads are heterocrine glands. These are also called mixed glands.

Hormones and their mechanism

Hormones are informational molecules secreted by the endocrine cells in one part of the body and carried by blood to another part where they stimulate or inhibit specific physiological process.

Discovery: First hormone discovered was secretin. It was discovered by two English physiologists: William M Bayliss and Ernest H. Starling in 1903.

Term hormone was coined by Starling (1905) from Greek word Homone means to excite. It is a misnomer because a number of hormones are known to have inhibitory effect (e.g., Somatostatin).

General function of hormones

- (1) Some hormones control Basal Metabolic Rate (BMR) e.g., thyroxine of thyroid gland.
- (2) Some hormones control the secretion of other endocrine glands, e.g., Tropic hormones of Anterior pituitary control Thyroid, Adrenal cortex, gonads, etc.
- (3) Some hormone control blood pressure e.g., Aldosterone, Atrial Natriuretic Hormone (ANH) of heart, Vasopressin or ADH', oxytocin and Renin of kidney.
 - (4) Increase production of RBC e.g., erythropoietin of kidney.

Properties of hormones

- (1) These are secreted by endocrine gland (biogenic in origin).
- (2) Their secretions is released directly into blood (except local hormones *e.g.*, gastrin).
- (3) These are carried to distantly located specific organs, called target organ.
- (4) These have specific physiological action (excitatory or inhibitory). These co-ordinate different physical, mental and metabolic activities and maintain homeostasis.
- (5) The hormones have low molecular weight e.g., ADH has a molecular weight of 600–2000 daltons.
- (6) These act in very low concentration e.g., around 10^{-10} molar.
 - (7) Hormones are non antigenic.
- (8) These are mostly short-lived. So have a no cumulative effect.
- (9) Some hormones are quick acting e.g., adrenalin, while some acting slowly e.g., oestrogen of ovary.
- (10) Some hormones secreted in inactive form called Prohormone e.g., Pro-insulin.
- (11) Hormones are specific. They are carriers of specific information to their specific target organ. Only those target cell respond to a particular hormone for which they have receptors.

UNIVERSAL BOOK DEPOT 1960

(12) Hormones after their action are destroyed in liver and kidney.

Classification of hormones

- (1) On the basis of chemical nature: On the basis of chemical composition hormones are classified into three categories.
- (i) **Amine hormones :** These are derived from tyrosine amino acid and have amino $(-NH_2)$ group e.g., Thyroxine, Epinephrine, Nor-epinephrine.
- (ii) **Steroids**: These are fat soluble and have sterol group. These are derived from cholesterol *e.g.*, hormones of adrenal cortex (cortisol, cortisone, corticosterone, aldosterone) testes (testosterone) and ovaries (oestrone, oestradiol, progesterone etc.)
- (iii) **Proteinaceous and peptide hormones**: These are formed of 3 200 amino acids interlinked by peptide bonds and are water soluble *e.g.*,
- (a) Proteinaceous hormones like STH, TSH, FSH, LH etc. Out of these FSH and LH are glycoproteins.
- (b) Long peptide hormones like insulin and glucagon, ACTH, Paratharmone.

- (c) Short peptide hormones like oxytocin, ADH, MSH. These hormones formed of a few amino acids.
 - (2) On the basis of mode of action
- (i) Quick acting hormones: These hormones initiate immediate response from their target cells. There receptor is always located on the outer surface of plasma membrane of target cell because these are large sized. Hormone receptor complex activates a membrane enzyme adenyl cyclase which hydrolyse ATP into cyclic AMP. Which acts as secondary messenger, c-AMP activates an inactive enzyme system by cascade effect. So their mode of action is called second messenger hypothesis. e.g., These includes proteinaceous, peptide and amine hormones.
- (ii) **Delayed acting hormones**: These hormones initiate response after some time. These are small sized so are diffusable through the plasma membrane of their target cell. These bind their proteinaceous receptor present in the cytosol. These always operate through de-novo synthesis of m-RNA by activation of certain genes. So their mechanism of action is called m-RNA hypothesis. These include steroid hormones of testes, ovary and adrenal cortex.

Table: 5.7-1 Difference between hormone and enzymes

S.No.	Characters	Enzymes	Hormones
1.	Chemistry	Always proteinaceous	May be proteinaceous, or amine or steroids.
2.	Molecular weight	Macromolecules with high molecular weights.	Have low molecular weights.
3.	Diffusibility	Non-diffusible through cell membrane.	Diffusible through cell membrane.
4.	Site of action	Either act intracellularly or carried by some duct to another site.	Generally carried by blood to a target organ.
5.	Mode of action	Always act as biocatalysts and increase the rate of metabolic physiological process.	May be excitatory or inhibitatory in their physiological action.
6.	Reversibility	These catalyze reversible reactions.	Hormone controlled reactions are not reversible.
7.	Effect of concentration	Reaction rate increase with increase in their concentration upto a limit.	Deficiency or excess of hormone causes metabolic disorders and diseases.
8.	Speed	Act quickly	Some are quick acting, while some are slow acting with a lag period.
9.	Consumption	Not used in metabolic functions.	Used up in metabolic functions.

Table: 5.7-2 Difference between hormone and vitamin

S.No.	Characters	Hormones	Vitamins				
1.	Source	Synthesized in the endocrine cells of body.	Taken along with food from outside.				
2.	Chemistry	Steroids or proteinous or amino acid derivatives.	Simple organic compounds like amines, esters, organic acids etc.				
3.	Action	Either excitatory or inhibatory. Do not act as co-enzymes.	These generally act as co-enzymes for enzyme activity.				
4.	Cause of disorders	Both excess as well as deficiency of hormones.	Generally avitaminosis (deficiency of vitamins) leads to deficiency diseases.				

Table: 5.7-3 Difference between Nervous and hormonal control

S.No.	Characters	Nervous control	Hormones control		
1.	Speed of action	Always quick acting.	May be quick acting or acting with a long period.		
2.	Mode of transmission of informations	As electrochemical nerve impulses.	As chemical messengers.		
3.	Path of transmission	Through nerve fibres.	Through blood.		
4.	Direction of the informations	Towards a specific direction (effector organ or CNS).	Released in general blood circulation from where taken by specific receptor.		
5.	Suitability	For quick reactions like reflexes.	For long-term changes e.g. maintenance of pregnancy.		
6.	Durability	Short time effect.	Long lasting.		

Release of hormones : Hormones are released from endocrine glands by three types of stimuli.

(1) **Specific metabolites**: The presence of a specific metabolite in the blood elicits the hormone to deal with it.

1006 Chemical Co-ordination and Integration

For instance excess of glucose in the blood causes the release of insulin from the pancreas and decrease of glucose in blood causes the release of glucagon from pancreas.

- (2) Other hormone: The presence of a specific hormone in the blood induces the release of another hormone. For example TSH stimulate thyroid gland to release thyroxine hormone and ACTH stimulate Adrenal cortex to release their hormones.
- (3) Neuronal impulse: Neurons of autonomic system stimulate hormone release from some glands. For example adrenaline and nor-adrenaline are released from adrenal medulla on the arrival of nerve impulses during anxiety, stress and danger.

Mechanism of hormone action: The hormones act in two ways.

- (1) On cell surface: The molecules of hormones that are amino acid derivatives, peptides or proteins are large and insoluble in lipid, and can not enter the target cell. Therefore they act at the cell surface. They bind to specific receptor molecules located on the surface of cell membrane. The hormone receptor complex may acts in one of the two ways -
- (i) Formation of cAMP: Mechanism of formation of cAMP was discovered by E.W. Sutherland in 1950. The hormone receptor complex causes the release of an enzyme adenylcyclase from the receptor site. This enzyme hydrolyse the ATP into c-AMP. The c-AMP activates the existing enzyme system of the cell. This accelerates the metabolic reactions in cell. The hormone is called first messenger and the c-AMP is termed the second messenger. e.g., Adrenaline causes the secretion of glucose from the liver cell from this mechanism.

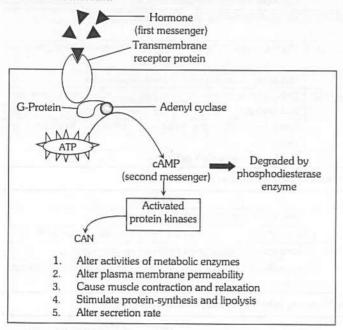

Fig: 5.7-1 Mechanism of Hormone action on cell surface

(ii) Change in membrane permeability: The receptor proteins of some hormones are large transmembrane intrinsic protein acting as ion channels for facilitated diffusion of Na+, K+, Ca2+ etc. On binding with specific hormone these receptor proteins undergo conformational changes, so that the membrane permeability for ions is altered, resulting into important changes in metabolism.

For example, insulin promotes the entry of glucose from blood into the muscle cells by increasing the permeability of sarcolemma to glucose.

(2) Within a cell: The steroid hormones act within the cell. Their small, lipid soluble molecules pass through the cell membrane and bind to specific receptor molecules present in the cytoplasm. The receptor molecules carry them into the nucleus. Here, the receptor hormone complex binds to a specific receptor site on the chromosome and activates certain genes that were previously repressed. The activated gene transcribe m-RNA which directs the synthesis of enzyme (protein molecule) in the cytoplasm. The enzyme molecule promote the metabolic reactions in the cell.

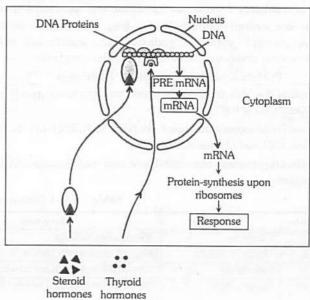

Fig: 5.7-2 Mechanism of cell surface within a cell

Feedback control of hormone secretion: The secretion of hormones depends on age, daily routine, health of body. physiological conditions of body etc. Besides the above factors hormone secretion also depends on its own amount circulating in the blood. Decrease and increase in the circulating amount of a hormone has a directly inverse effect on the secretion of hormone. This is known as the "pull and push" or "feed-back control" mechanism of hormonal secretion.

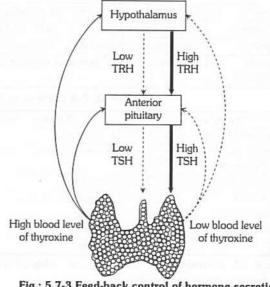

Fig: 5.7-3 Feed-back control of hormone secretion

(1) Negative feedback control

Direct feedback control: Thyroid stimulating hormone (T.S.H.) stimulates the thyroid gland to secrete thyroxine hormone. A high amount of thyroxine in the blood exerts an inhibitory effect on pituitary to secrete less T.S.H.. This eventually results in decrease in thyroxine. This is called "Direct feedback control".

(2) Positive feedback control: Oxytocin released by posterior pituitary gland stimulate contraction of uterus during child birth. As the contraction of uterus progresses, more and more of oxytocin is released. This is called positive feed back control.

Table: 5.7-4 Origin of different endocrine glands

		and the second s
Endocrine glands	Weight	Origin
Pituitary	0.5 gm	Ectoderm
Pineal	5.0 mg	Ectoderm
Thymus (upto 12 yrs.)	20.0 gm	Endoderm
Thyroid	25.0 gm	Endoderm
Parathyroid	20.0 mg	Endoderm
Adrenal cortex	4.0 gm	Mesoderm
Adrenal medulla	1.0 gm	Ectoderm
Testes		Mesoderm
Ovary		Mesoderm
Pancreas	60.0 gm	Endoderm

Discovery & Terms

- (1) Term 'endocrine' was first used by Claude Bernard.
- (2) Thomas Addison is called as father of endocrinology.
- (3) Walter canon stated that the hormones maintain homeostasis in the body.
 - (4) Von Euler coined the term 'prostaglandin'
 - (5) Kendall for the first time prepared the crystals of thyroxine.
- (6) Harrington and Barger studied the molecular structure of thyroxine.
 - (7) Term 'thyroxine' was coined by Whartson.
 - (8) Sutherland discovered cAMP.
 - (9) Parathormone was first isolated by Collip.
 - (10) Potts discovered the structure of PTH.
- (11) Axelord studied the structure of epinephrin and nor-epinephrin.
- (12) Endocrine structures of the pancreas were discovered by langerhans.
- (13) Structure of insulin was studied by Sanger. He was given Nobel prize in 1958. He was rewarded Nobel prize in 1980 for gene structure.
 - (14) Human insulin was synthesized by Tsan.
 - (15) Glucagon was discovered by Kimball and Murlin.
 - (16) Term 'Secretin' was coined by Beylis and Starling.
 - (17) Adrenal gland was discovered by Eustachian.

Pituitary Gland (Hypophysis)

Pituitary is known as hypophysis cerebri, its name pituitary was given by Vesalius. Muller's gland of amphioxus and subneural gland of hardmania is homologous to pituitary of vertebrates. Weight of pituitary is 0.5 gm. Removal of pituitary is known as hypophysectomy.

Position and origin: Pituitary gland is the smallest (about 1 to 11/2 cm in diameter) endocrine gland of the body. It is peashaped, ovoid, reddish brown gland situated at the base of the brain in a cavity, hypophyseal fossa of the sella turcica of sphenoid bone. It is connected by a short stalk called Infundibulum, to the ventral wall (Hypothalamus) of diencephalon. That is why it is also called hypophysis cerebri. It weight about 0.5 to 1 gm. It control most of the endocrine glands. Hence, it is also called leader of endocrine orchestra or master gland. Pituitary gland is closely related with hypothalamus, hence, it is also called hypothalamohypophyseal gland, pituitary is ectodermal in origin.

Parts and component

Adenohypophysis

- (1) Pars distalis
- (2) Pars tuberalis
- Anterior lobe 75%
- (3) Pars intermedia

Neurohypophysis

- (1) Pars nervosa
- Posterior lobe 25%

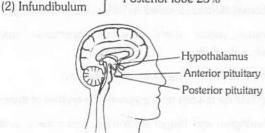

Fig: 5.7-5 Location of pituitary gland

Structure of pituitary gland: Pituitary gland is comprised of two main lobes - Adenohypophysis and Neurohypophysis. Adenohypophysis arises as hypophyseal or Rathke's pouch from dorsal wall of embyronic stomodeum. It is the anterior lobe of pituitary. The neurohypophysis (Pars nervosa or Posterior lobe) form as an outgrowth from the infundibulum of the floor of hypothalamus.

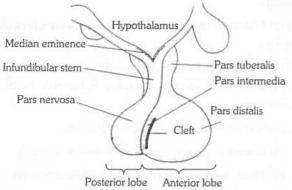

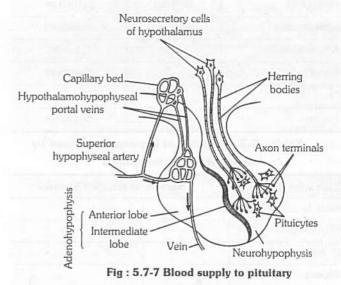

Fig: 5.7-6 Structure of pituitary gland

In pituitary following types of cells are found:

- (1) Chromophobes cells: Found in adenohypophysis of pituitary. These are not stained by acid and base dye. Pigment granules are absent. These are colourless may change into chromophils.
- (2) Chromophil cells: Found in adenohypophysis of pituitary. These are stained by acid and base dve. Pigment granules are filled in these cells. These may be two types :
- (i) Acidophils : It is also known as α -cells synthesize and secretes growth hormone and prolactin.
- (ii) Basophils: It is also known as cyanophils or β-cells synthesize and secretes TSH, ACTH, FSH, LH and MSH hormones.
- (3) Pituicyte cells: These cells found in neurohypophysis of pituitary. These are supporting neuroglea cells and gives support to herring bodies.
- (4) Herring bodies: Herring bodies are dilated terminal portion of Neurosecretory axon constituting hypothalamohypophyseal tract. They are hormone precursors for oxytocin and vasopressin.

Blood supply to pituitary or Hypophyseal portal system: A pair of posterior hypophyseal arteries and a pair of anterior hypophyseal arteries provide blood to the pituitary gland. Posterior arteries supply blood to the pars nervosa, and anterior arteries supply blood to the hypothalamus and pars distalis. Adenohypophysis has dual blood supply by means of a "circle of willis". The anterior hypophyseal artery which bring blood into this circle big ureates into two branches outside the lobe. One branch supplies the adenohypophysis and other supplies the hypothalamus. The veins that drain the blood from hypothalamus. Then run into the pars distalis through pars tuberalis and divide into capillaries. Those veins are therefore, called portal hypophyseal veins. These constitute a hypothalamo hypophyseal portal system. Hypothalamic hormone reached anterior pituitary by portal system.

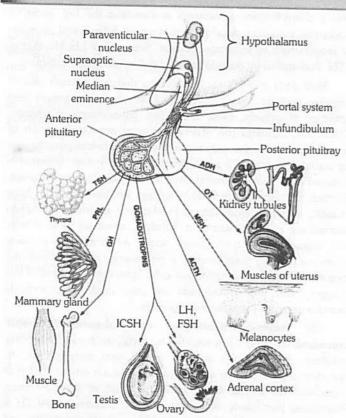

Fig: 5.7-8 Diagram to show the hormones of adenohypophysis and their target tissues and organs

Hormones of adenohypophysis

Adenohypophysis secretes seven hormones which are proteinacious in nature. These hormones are controlled by the controlling factors, secreted by the hypothalamus. There are 9 main controlling factors. Out of them 7 are releasing factors (RF) and 3 are inhibiting factor (IF). Complete failure of adenohypophysis (ant. pituitary) leads to simmonds syndrome. Hormones that influence another endocrine gland are called tropic or tropin hormones. The FSH/LH regulate testes and ovaries, thyrotropin stimulate thyroid, whereas corticotropin act on cortex of adrenal gland. Various hormones of adenohypophysis are as follows -

(1) Somatotropin (STH) or Growth Hormone (GH)

(i) Functions of growth hormone: Molecules of this hormone are polypeptides of 191 amino acid monomers. It is the major hormone in the secretion of anterior pituitary. It is the most important stimulant of proper normal growth of body. It promotes biosynthesis of DNA, RNA and proteins in all body cells. thus, it acts as an anabolic growth factor. Obviously, it stimulates cellular growth and proliferation, growth and repair of bones, muscles and connective tissue. In the liver cells it promotes, glycogenesis, deamination and gluconeogenesis.

According to modern scientists, the anabolic effects of growth hormone in man are indirect, instead of being direct. This hormone triggers synthesis of certain special, insulin-like growth factors (IGFs) in cells of many tissues, such as liver, muscles, cartilages, bones, etc. These growth factors are called somatomedins.

(ii) Control of the secretion of growth hormone: Secretion of growth hormone is controlled by two hormonal factors secreted by cells of hypothalamus. One of these factors, called GH-release hormone (GHRH) promotes secretion of growth hormone, while the other called GH-inhibitory hormone (GHIH) retards the secretion of growth hormone by the anterior pituitary. GHRH is also called somatocrinin and GHIH is called somatostatin.

(iii) Effects of hyposecretion of growth hormone

- (a) Nanism or ateliosis: Hyposecretion (undersecretion) of growth hormone is childhood results into a blunted growth of body. Growth of all organs is retarded. Growth of bones at their epiphyseal ends stops. Hence, the bones do not grow in length, so that the body remains a dwarf. This pituitary dwarfism is called nanism or ateliosis.
- (b) Midgets: Unlike the thyroid cretinism, the development of brain is normal in pituitary dwarfs, but like thyroid cretinism, the pituitary dwarfs are also infertile. The dwarfs of circuses are pituitary dwarfs. these are called midgets.
- (c) Pituitary myxoedema: Undersecretion of growth hormone during adolescence (between 13 to 22 years of age) restricts body height, so that the person remains short-statured. Undersecretion after growth period (about the age of 22) causes pituitary myxoedema whose symptoms are almost similar to those of thyroid myxoedema. These include old age symptoms, such as reduced BMR and protein synthesis, greying and falling of hair, pallor and dryness of skin, reduced BP and low body temperature, insomnia, and weakness of muscles, vision and wisdom. Due to accumulation of mucus under the skin, the body becomes puffy, but weak. Genitalia weaken, causing sexual disability. Hence, the person becomes disheartened.

(iv) Effects of hypersecretion of growth hormone

- (a) Proportionate gigantism: Hypersecretion (oversecretion of growth hormone during growth period (childhood and adolescence) causes excessive growth (hypergrowth) of all body parts, resulting into a symmetrically giant body. This is called proportionate gigantism.
- (b) Disproportionate gigantism or acromegaly: The concerned person may attain a height of 8 feet or ever more.

Oversecretion of growth hormone after growth period also causes gigantism, but in this the long bones do not grow in length due to closed epiphyseal plate at their ends, but the bones of hands, feet, lower jaw and rib cage thicken.

Simultaneously, eyelids, lips, tongue, nose, chin, etc also enlarge. Soles, palms

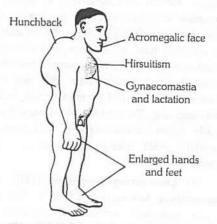

Fig: 5.7-9 A typical case of acromegaly

and forehead become wrinkled. Skin thickens and becomes wrinkled. Skin thickens and becomes coarse and fluffy (hirsutism).

Consequently, the body becomes ugly like a gorilla. This is called disproportionate gigantism or acromegaly. It is common in men and rare in women.

- (c) Kyphosis: In some cases, the backbone bends and thickens, causing hunchback condition (kyphosis). Breasts enlarge and mammary gland may yield milk. The patients often complain of headache, sexual disorders, muscular pain, and impaired vision and memory.
- (d) Diabetes mellitus: Hypersecretion of growth hormone raises blood glucose level (hyperglycemia) which may cause diabetes mellitus.
- (e) Ketosis: Increased breakdown of fat may release ketone bodies, mainly acetoacetic acid, in blood, causing ketosis.
- (2) Prolactin (PRL), Lactogenic, Luteotropic (LTH), or Mammotropic (MTH) Hormone: It is secreted by the lactotroph cells of anterior pituitary. Its molecules are polypeptides of 198 amino acid monomers. Its secretion by anterior pituitary is enhanced by prolactin-release hormone (PRH) and suppressed by prolactin inhibitory hormone (PIH) of hypothalamus. PIH is also called dopamine. In humans, it may act as a mild growth hormone, but its main physiological effect is to activate growth of breasts during pregnancy and secretion of milk by mammary glands after childbirth. That is why, it is often referred to as "maternity hormone". In some other mammals, and probably in women also, it stimulates corpus luteum of ovaries to continue secreting progesterone, hormone during pregnancy. Prolactin levels rises during pregnancy due to PRH of hypothalamus.

Hypersecretion: (i) Prolactin hormone is secreted both in males as well females. In males it influence sexual behaviour. Its hypersecretion may hinder menstruation.

- (ii) May cause impotency
- (iii) In pigeons and doves, it stimulates the epithelial cells of crop in both males and females to secrete "pigeon milk" for nutrition of newly hatched infants.
- (3) Follicle-stimulating hormone (FSH) or Gametokinetic factor: It is a glycoprotein whose molecules consists of a polypeptide of 204 amino acid residues. It stimulates growth of seminiferous tubules and spermatogenesis in men, and growth of ovarian follicles and oogenesis in women. In women, it also stimulates secretion of female sex hormones (oestrogens) by the cells of ovarian follicles. Under the negative feedback regulation, the principal male (testosterone) and female (oestradiol) hormones retard secretion of FSH. In women, the effect of FSH on ovaries considerably decreases after the age of 40. Consequently oogenesis, secretion of oestrogens and menstruation decline and ultimately stop. Termination of menstruation is called menopause. GnRH (gonadotropin-releasing hormones) from hypothalamus stimulates FSH release. There is no gonadotropin inhibiting hormone.
- (4) Luteinizing hormone (LH), or Interstitial cellstimulating hormone (ICSH): This is also a glycoprotein whose molecules contain a polypeptide of 204 amino acid residues. In men it stimulates the growth and function of the interstitial cells of testes (cells of Leydig), which secrete the male hormones (androgens) to regulate the development of secondary

sexual characteristics. In women, it stimulates the last stages of oogenesis, ovulation, development of corpus luteum and secretion of progesterone by the corpus luteum. Secretion of LH, like that of FSH is controlled by gonadotropin-releasing hormone (GnRH).

Both FSH and LH are secreted by the gonadotroph cells of anterior pituitary. Since both of these stimulate growth and activities of gonads, these are called gonadotropic hormones. These also activates the accessory genital organs. Secretion of these hormones begins only two to three years before puberty (age of sexual maturity – 12 to 14 years). Obviously their secretion is initiated by a "Genetic biological clock", located in hypothalamus. Further, the secretion of FSH in women are also regulated by a "Clock", located hypothalamus. Further, the secretion of FSH in women are also regulated by a "Clock of menstrual cycle". Under the regulation of both these clocks a gonadotropin-release hormone (GnRH) is secreted by hypothalamus and influences the activities of pituitary gonadotroph cells. Synthetic hormones of this category and their antagonists are now used to respectively activate or retard the activities of gonads.

- (5) Adrenocorticotropin or Adrenocorticotropic hormone (ACTH): It is secreted by corticotroph cells of anterior pituitary. Its molecules are 39 amino acid polypeptides. Its secretion is prompted by a corticotropin-release hormone (CRH) of hypothalamus. Its role is to intensify synthesis of adrenal cortical hormones, particularly the glucocorticoids. Secretion of ACTH is stimulated by low blood level of glucose, shock conditions and presence of a compound called interleukin-1 (IL-1) secreted by macrophages. Under a direct negative feedback regulation, the concentrations of glucocorticoids in blood affect the secretion of both ACTH and CRH. Hyposecretion of ACTH leads to rheumatic arthritis.
- (6) Thyrotropin or Thyroid-stimulating hormone (TSH): It is also a glycoprotein secreted by thyrotroph cells of anterior pituitary. The polypeptide of its molecule has 201 amino acid residues. Its secretion is stimulated by a hypothalamic thyrotropin-release hormone (TRH). It promotes growth and function of thyroid gland. Under the negative feedback regulation, the secretion rate of hypothalamic TRH depends on blood levels of TSH, thyroxine and glucose, and on metabolic rates of body cells. There is no thyrotropin-inhibiting hormone.
- Melanocyte-stimulating hormone (MSH) Melanotropin: It was formerly called intermedin secreted by pars intermedia. This may be the condition in other vertebrates, but in humans, it is secreted by remnant cells of this lobe, which become a part of pars distalis. Its molecule is a small peptide of 13 amino acid residues. Its secretion is controlled by hypothalamic hormones, viz MRH (Melanocyte releasing hormone) and MIH (Possibly oxytocin is released at this time by posterior pituitary of both mother and the fetus. At actual Melanocyte inhibiting hormone). In lower vertebrates, the target cells of this hormone are the melanophores. Melatonin is antagonistic to melanocyte stimulating hormone MSH affects spreading of the melanin granules in these cells so that skin colour darkens in fish and amphibian but in birds and mammals of the role of MSH is uncertain. In man, presence of MSH receptor in brain suggests it may influence brain activity.

UNIVERSAL BOOK DEPOT 1960

(8) Metabolic hormone (MH): It influence carbohydrate and fat metabolism of body. The hormone which influence carbohydrate metabolism is known as diabetogenic hormone. The hormone which influence fat metabolism is known as ketogenic hormone.

Hormones of neurohypophysis and their functions

The herring bodies of neurohypophysis contain two hormones – vasopressin and oxytocin – which are released from axon terminals by exocytosis and diffuse into adjacent blood capillaries when needed. These are secreted by paraventricular nucleus and supra-optic nucleus respectively. Both vasopressin and oxytocin are proteinous in nature.

(1) Vasopressin: The principal role of this hormone is to promote reabsorption of water from the distal convoluted tubules of nephrons and collecting ducts reducing excretion of water in urine (diuresis). That is why, it is also called antidiuretic hormone (ADH). Its release into blood is controlled by an "osmoregulatory centre" located in hypothalamus. Another effect of vasopressin is to increase blood pressure by contracting blood vessels (vasoconstriction) in several tissues; hence the name vasopressin.

Effect of vasopressin

- (i) Vasoconstriction of the blood vessels of skin by this hormone retards secretion of sweat glands.
 - (ii) It also stimulates contraction of intestinal smooth muscles.
- (iii) When vasopressin is released in excessive amounts, the urine becomes concentrated and blood is diluted, increasing BP.

The osmo-regulatory centre, then, issues motor impulses to check release of vasopressin.

- (iv) When vasopressin is released in smaller amounts, diuresis increases; urine becomes diluted and blood becomes concentrate, amounts, diuresis increase; urine becomes diluted and blood becomes concentrated, decreasing BP.
- (v) In acute diuresis, quantity of urine may increase to about 20 litres instead of normal 1 to 2 litres per day. This condition is called polyuria or diabetes insipidus (passing of watery; tasteless urine). It causes dehydration of body and thirst.
- (2) Oxytocin (Child birth hormone): This hormone stimulates contraction of uterine muscles, inducing labour pains for child birth (parturition) when secretion of progesterone hormone from the placenta declines, making the end of pregnancy. As the sensory impulse of increasing labour pain reaches hypothalamus, more and more oxytocin is released from posterior pituitary under a positive feedback regulation, it dilates the cervix (vaginal stretching). After childbirth, it helps in normalization of the uterus and contracts breast muscles and lactic ducts to facilitate release of milk (lactation) during sucking oxytocin stimulates milk ejection so has a galactogogic effect.

Master gland: As is clear from above account, the pituitary gland plays most important regulatory role in the body. Besides regulating growth, sex and general behaviour, it also regulates the secretory activities of other principal endocrine glands and cells. Most appropriately, therefore, pituitary has been referred to as "The Master Gland" of body, or the "Chief Executive of Endocrine System", or "The Leader of Endocrine Orchestra".

Table: 5.7-6 Summary of the Principal Action of Anterior Pituitary Hormones

Hormone and Target Tissues	Principal Action	Hormone and Target Tissues	Principal Action
Human growth hormone (hGH) or somatotropin	Stimulates liver, muscle, cartilage, bone, and other tissues to synthesize and secrete insulin like growth factor of body cells, protein synthesis, tissue repair, glucose concentration.	Prolactin (PRL) Mammary glands	Together with other hormones, promotes milk secretion by the mammary glands.
Thyroid-stimulating hormone (TSH) or thyrotropin Thyroid gland	Stimulates synthesis and secretion of thyroid hormones by thyroid gland.	Adrenocorticotropic hormone (ACTH) or corticotropin Adrenalcortex	Stimulates secretion of glucocorticoids (mainly cortisol) by adrenal cortex.
Follicle-stimulating hormone (FSH) Ovaries Testes	In females, initiates development of oocytes and induces ovarian secretion of oestrogens. In males stimulates testes to produce sperm.	Melanocyte-stimulating hormone (MSH)	Exact role in humans is unknown but may influence brain activity, when present in excess, can cause darkening of skin.

Table: 5.7-7 Summary of Posterior Pituitary Hormones

Hormone and Target Tissues	Control of Secretion	Principal Actions
Oxytocin (OT) Uterus Mammary glands	Neurosecretory cells of hypothalamus secrete OT in response to uterine distention and stimulation of nipples.	Stimulates contraction of smooth muscle cells of uterus childbirth; stimulates contraction of myoepithelial cells in mammary glands to cause milk ejection.
Antidiuretic hormone (ADH) or vasopressin Sudoriferous (sweat) glands Arterioles	Neurosecretory cells of hypothalamus secrete ADH in response to elevated blood osmotic pressure, dehydration loss of blood volume, pain, or stress; low blood osmotic pressure, high blood volume, and alcohol inhibit ADH secretion.	Conserves body water by decreasing urine volume; decreases water loss through perspiration; raises blood pressure by constricting arterioles.

Hypothalamus

Position and Structure: Hypothalamus is the floor of diencephalon. It is formed of masses of grey matter, called hypothalmic nuclei, containing neurosecretory cells. It is connected with anterior pituitary lobe by blood capillaries of hypophyseal portal system and with the posterior pituitary lobe by axons of its neurons, both passing through the pituitary stalk.

Hormones of hypothalamus: Neurosecretory cells of hypothalamus secrete neurohormones called releasing factors (RF) or inhibiting factors (IF). These neurohormones are carried by hypophyseal portal system to adenohypophysis (primary target organ) and stimulate or inhibit the release of trophic hormones from adenohypophysis. These neurohormones are proteinaceous in nature and formed of 3-20 amino acids.

Table: 5.7-8 Neurohormones of Hypothalamus

S.No.	Neurohormones	Physiological effects	
1.	TRH (Thyroid Releasing Hormone – Releasing Factor)	Increased TSH secretion from adenohypophysis.	
2.	ACTH-RF (Adrenocorticotrophic Hormone-Releasing Factor)	Increased ACTH secretion from adenohypophysis.	
3.	STH-RF		
	(Somatotrophic Hormone-Releasing Factor)	Increased STH secretion from adenohypophysis	
4.	SOMATOSTATIN (GROWTH INHIBITING HORMONE)	Decreased STH secretion from adenohypophysis.	
5.	GTH-RF (Gonadotrophic Hormone-Releasing Factor)		
	(i) FSH-RF (Follicular Stimulating Hormone-Releasing Factor)	Increased FSH secretion from adenohypophysis.	
	(ii) LH-RH (In female)		
	(Luteinising Hormone – Releasing Factor)	Increased LH secretion from adenohypophysis.	
	or ICSH-RF (In male)		
	(Interstitial Cells stimulating Hormone-Releasing Factor)		
6.	Prolactin-Releasing hormone (P-RH)	Increased secretion of prolactin or leuteotrophic hormone.	
7.	Prolactin-Inhibiting hormone (P-IH)	Decreased secretion of prolactin or leuteotrophic hormone.	
8.	MSH-RF (Melanophore Stimulating Hormone-Releasing Factor)	Increased MSH secretion from intermediate pituitary lobe.	
9.	MIF (Melanophore Inhibiting Factor)	Decreased MSH secretion from intermediate pituitary lobe.	

Hypothalamo – pituitary complex : Pituitary gland is closely related with hypothalamus. Both together form hypothalamo-pituitary complex.

The hypothalmic-pituitary (hypothalamo-hypophyseal) system is a direct proof of coordination between the hormonal and nervous system. It regulates most of the physiological activities of body and maintains homeostasis inside the body. These neurosecretory cells are known to synthesize two more hormones: Oxytocin and Vasopressin, which are stored in their axons extending in the posterior lobe of pituitary gland.

Thyroid gland

The name "thyroid" was introduced by Thomas Wharton (1656). It is derived from Greek "Thyreos" a shield.

Location: This is the largest endocrine gland of our body. It is located in our neck upon the ventral aspect of larynx (sound box or Adam's apple) and a few anteriomost tracheal rings. It is a dark brown and H-shaped/butterfly bilobed gland.

UNIVERSAL BOOK DEPOT 1960

Origin: It is endodermal in origin and arises in the embryo as a midventral process from the floor of the tongue in pharyngeal region between the first and second pharyngeal pouches. Later, the duct-like connection (thyroglossal duct) of the process degenerates, so that the process is separated from the tongue and becomes endocrine. Probably, the gland is homologous to the endostyle of lower chordates.

Structure of thyroid gland: In adult human beings, thyroid gland measures about 5 cm in length and 3 cm in width. It's average weight is 30 grams. It is somewhat larger in women. In old age, it becomes somewhat smaller as age advances. Its two lobes are connected by a narrower isthmus formed of nonglandular connective tissue. A small, conical pyramidal lobe is often found extended forwards from the isthmus. The whole gland is enveloped by a fibrous capsule. Thin septa or trabeculae, extending inwards from the capsule, divide the gland into a number of lobules. Each lobule, in turn, consists of a large number of small and hollow, spherical follicles (acini) embedded in a small amount of a loose connective tissue that forms the stroma of the gland.

The wall of each thyroid consists of a single-layered cuboidal epithelium suspended from a basal lamina, while its cavity is filled with a yellowish, jelly-like and iodinated colloid glycoprotein substance, called iodothyroglobulin. Besides containing a dense network of blood capillaries, the stroma contains small clusters of specialized parafollicular or 'C' cells. The latter are remnants of ultimobranchial bodies derived from the fifth pharyngeal (branchial) pouches in the embryo.

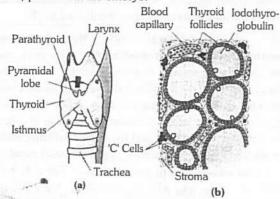

Fig : 5.7-10 (a) Thyroid gland,

Synthesis and storage of iodothyroglobulin: Synthesis of a glycoprotein thyroglobulin (TGB) - occurs continuously in the follicular cells under genic control. The cells keep extruding thyroglobulin in follicular cavity by exocytosis. Each molecule of thyroglobulin contains about 500 amino acid monomers of which 123 monomers are of tyrosine at fixed places. Soon as the molecules of iodine and thyroglobulin come out of follicular cells, these interact in such a way that 15 tyrosine monomers of each thyroglubulin molecule at fixed places become iodinated. Certain tyrosine monomers bind with single atoms of iodine, forming monoiodotyrosine (MIT or T1). Other tyrosine monomers bind with two atoms of iodine, forming diiodotyrosine (DIT or T2). This is of thyroglobulin. organification Molecules iodothyroglobulin keep accumulating in follicular cavity, forming jelly-like colloid. Within the colloid, molecules iodothyroglobulin undergo conformational changes and may even

interact with each other. This results in a coupling of most of the iodinated tyrosine monomers in pairs. This coupling may occur between the iodinated tyrosine monomers of the same or different molecules of iodothyroglobulin. It results in the formation of several groups of complexes of tetraiodothyronine (thyroxine $-\,T_4)$ and some of triiodothyronine (T_3) in the colloid. Each T_4 complex obviously contains two tyrosine monomers and four atoms of iodine, whereas each triiodothyronine complex contain two tyrosine monomers and three atoms of iodine. T_4 and T_3 are actually the iodinated hormones secreted by thyroid. Obviously, the colloid acts as a reservoir of these hormones.

The daily output of thyroid glands is about $80\mu g$ (0.08mg) of T_4 and about $4\mu g$ of T_3 . Since, however T_3 is several times more potent, most of the T_4 molecules also change into T_3 molecules by losing one iodine atom as these diffuse from blood into ECF. This deiodination of T_4 is maximum in the liver.

As described in a preceding account, the rate of thyroid secretion is controlled by pituitary gland and the hypothalamus of brain respectively under direct and indirect negative feedback regulation. Rate of thyroid secretion increases during winters and in pregnant women.

Synthesis and secretion of iodinated hormones

Iodides and Iodine: An adult human body contains about 5 to 6 milligram of iodine and most of it is found in thyroid gland. Thus, the thyroid is a reservoir of iodine. For secreting the iodinated hormones in normal amounts, the thyroid daily utilizes about 150 micrograms (0.15 milligram) of iodine. Obviously, a person must daily obtain 150μg of iodine from food. We can obtain this from dairy products, drinking water, seafood, *etc.* If obtained more than this, we excrete the excess iodine in urine.

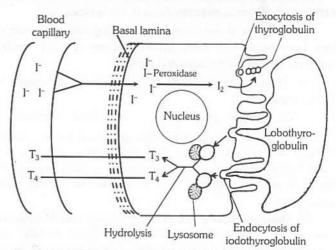

Fig: 5.7-11 Working mechanism of follicular cells of thyroid

lodine of food is absorbed and circulated in blood in the form of iodide ions (I⁻). Follicular cells of thyroid very actively obtain these ions from blood by active transport. That is why, the concentration of I⁻ in these cells normally remains about 50 to 250 times more than in blood. These cells possess peroxidase enzyme in abundance. Peroxidase continuosly oxidizes iodide ions into molecular iodine ($2I^-\rightarrow I_2$). Iodine is, then, released by follicular cells into follicular cavity.

Hormones of thyroid

Thyroid gland secretes two iodinated hormones. Thyroxine (T_4) and Tri iodothyronine (T_3) and one non iodinated hormone thyrocalcitonin. Secretion of thyroid gland is regulated by TSH of anterior pituitary lobe. Thyroxine was first isolated by Kocher (1914) but was first crystalized by Kendall (1919). Its molecular structure was given by Harrington and Berger (1927). They also synthesized thyroxine.

- (1) **Thyroxine**: It is an iodine containing (6% iodine) amine hormone which is derived from tyrosine amino acid. Chemically thyroxine is tetraiodothyronine though also found as triiodothyronine. Secretion of thyroxine is inversely proportional to the blood level of thyroxine (feed back mechanism). These hormones perform following functions:
- (i) These regulate Basal Metabolic Rate (BMR) of the body as control rate of cell respiration and energy production in mitochondria hence the "Tempo. of life". So these control physical, mental and sexual growth of body. It is called calorigenic effect.
- (ii) In 1912 Gudernatsch discovered that metamorphosis in frog's tadpole begins only when adequate amount of thyroxine is secreted by the thyroid of the tadpole. It was also found that hyposecretion of thyroxine retards and hypersecretion enhances the rate of metamorphosis.

In the hilly tracts of North America from whose soil all iodine has been washed away by rain water, the tadpoles of *Ambystoma* probably never metamorphose. Therefore, these tadpoles grow to a large size and attain sexual maturity, *i.e.*, these become paedogenetic larvae. This phenomenon is called paedogenesis. The paedogenetic larvae of *Ambystoma* are called *Axolotl* larvae.

Addition of thyroxine or iodine in pond water naturally induces and enhances metamorphosis in the tadpoles.

- (iii) Functions of osmo-regulation and regulation of moulting have been ascribed to these thyroid hormones in cold-blooded vertebrates (fishes, amphibians and reptiles).
- (iv) These control working by renal tubules of kidney so control urine output.
 - (v) These help in homeothermy in warm blooded animals.
- (vi) Synthesis of additional sodiumpotassium pump (Na^+/K^+ ATPase), which then use more ATP more heat is given off, and body temperature rises. This phenomenon is called calorigenic effect of thyroid hormone, and thus maintain normal body temperature.
- (2) **Thyrocalcitonin** (TCT): It is a long peptide hormone secreted by parafollicular cells of thyroid gland (C-cells). It's secretion is regulated by increased plasma level of calcium by feedback mechanism. TCT lowers calcium level in blood to normal by increasing calcium deposition in the bones, so checks osteoporosis and stimulates excretion of calcium in urine. It prevent hypercalcaemia. Decreasing reabsorption of calcium from urine, so increasing excretion of Ca^{2+} . So it prevents hypercalcaemia.

Irregularities of thyroid gland

(1) **Hypothyroidism**: (Decreased secretion of thyroxine from thyroid gland). It leads to the following diseases –

- (i) **Cretinism**: It is disease of infants, called cretins. It is characterised by decreased BMR (50% than normal); stunted growth; retarded mental development so low I.Q., delayed puberty; decreased body temperature, heart rate, pulse rate, blood pressure and cardiac output; reduced urine output; decreased sugar level in blood, pigeon's chest (chest bulging forward in sternal region). Cretinism can be congenital (absence of thyroid due to genetic defect) or endemic (absence of iodine in diet). It can be corrected by thyroxin administration.
- (ii) Myxoedema: It occurs due to deficiency of thyroxine in adults. Like cretinism, it also has low (BMR) (by 30-40%); low body temperature, reduced heart rate, pulse rate, blood pressure and cardiac output, low sugar and iodine level in blood etc. But the peculiar feature of myxoedema is that face and hands become swollen due to deposition of albuminous myxomatous tissue. It can also be corrected by thyroxine administration.
- (iii) **Endemic or simple goitre or colloid goitre:** It occurs due to deficiency of iodine in drinking water. It is nongenetic (sporadic goitre is a genetic disease). It is characterized by enlargement of thyroid gland due to increase in number and size of acinal cells of thyroid gland. It is more common in people of hilly region. To prevent goitre, the table salt is being iodised these days.
- (iv) **Hashimoto's disease**: It is called auto-immune thyroiditis and occurs due to age factor, injury-surgery, wrong treatment or infection of thyroid gland causing hyposecretion of thyroxine. When thyroxine secretion falls upto minimal limit, the antibodies are formed which destroy the thyroid gland.
- Hypersecretion of thyroid hormones (Hyperthyroidism or thyrotoxicosis): This may also be a genetic defect, but usually it is provided by chronic infections (influenza, rheumatism, tonsilitis, tuberculosis, measles, whooping cough, etc.) pregnancy, intake of large doses of iodine, overeating, etc. It results into a considerable increase in glucose and oxygen consumption by cells and the rate of oxidative metabolism in the mitochondria. Consequently, the BMR (basal metabolic rate) may increase several folds (hypermetabolism). The cells fail to store all catabolic energy into ATP. Consequently, the extra energy is liberated as heat. Instead of causing growth of body, this energy, thus, overheats the body, causing nervous tension-and excitement, restlessness and anxiety, muscular weakness (thyrotoxic myopathy), fatigue and tremors, high temperature, palpitation of heart, copious sweating, diarrhoea, insomnia, trembling of limbs and body, weight loss, heat intolerance, warm and soft skin, increased appetite, etc.

Under his "Sodium pump theory of thermogenesis" Edelman has recently (1974) hypothesized that overheating of body in hyperthyroidism is not because cells fail to trap the excess catabolic energy in ATP, but because the excess ATP formed in this condition is utilized in considerably accelerating the Na^+ – K^+ pump, releasing more heat that overheats the body.

(i) **Simple goitre**: Hyperthyroidism may be simply because of overactive cells of a normal gland, or because of an enlargement of the gland, causing goitre.

- (ii) **Exophthalmic goitre :** Such a goitre is called exophthalmic goitre, because it is usually accompanied with some asymmetrical protrusion (Exophthalmos) of the eyeballs, imparting an angry, frightened, or staring look to the patient. Protrusion of eyeballs is due to accumulation of mucus in eye orbits.
- (iii) Grave's or Basedow's disease: Enlargement of the gland is usually due to a diffused growth.
- (iv) Plummer's disease or Toxic Adenoma: It is due to formation of one or more hypersecretory nodules.

Parathyroid gland

(1) **Position and structure**: These are four in number which are wholly or partially embedded in the dorsal surface of the thyroid gland two glands in each lobe of thyroid gland. Each is oval shaped, small sized (5×5 mm) and yellow coloured. Histologically, a parathyroid gland is formed of two masses of polygonal cell arranged in cords. Endocrine cell are of two types principal or chief and oxyphil cells. Parathyroid is endodermal in origin.

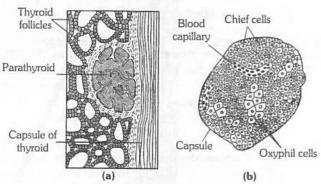

Fig: 5.7-12 (a) Parathyroid gland embedded in the surface of thyroid, (b) Ultrastructure of a parathyroid

(2) Hormones of parathyroid: Active hormone secreted by parathyroids is parathormone (PTH), also called Collip's Hormone (Phillips collip, 1925). It was discovered and purified by Collip in 1925. Its crystals were first prepared by Craig and Ras mussen in 1960. Its molecular structure was worked out by Potts and his associates in 1971. The latter is a protein of 84 amino acid monomer. It is a polypeptide hormone. Parathyroids are present in all vertebrates except fishes. Its secretion is stimulated by low level of calcium in blood than normal level through feedback control.

Functions of parathormone: Parathormone is essential for survival, because it significantly contributes to "homeostatis" by regulating the amount of calcium and phosphate ions in ECF. Parathormone maintains optimum level of plasma calcium by

- (i) Mobilisation from bones
- (ii) Reduced urinary excretion
- (iii) Increased absorption from intestine.

The level of phosphorus is not allowed to remain high by stimulating its urinary excretion. Our body requires an optimum calcium level (10.0 to 11.5 mg per 100 mL.) in ECF (total 1000 to 1120 grams in a 70 kg man), because calcium is a key element in many physiological functions like proper permeability of cell

membranes, muscular activities, nerve impulse conduction, heartbeat, blood coagulation, bone formation, fertilization of ova, etc. Calcium is most abundant of all minerals found in the body and about 99% of calcium and phosphorous are contained in the bones.

Maintenance of proper calcium level under 'homeostasis' is, in faci, a combined function of parathormone, thyrocalcitonin and vitamin D_3 (cholecalciferol). Parathormone promotes absorption of calcium from food in the intestine and its reabsoption from nephrons in the kidneys. Simultaneously, it accelerates elimination of phosphates in urine (phosphaturic action). Thus, calcium level tends to rise in the ECF due to the effect of parathormone. This calcium is, then, utilized by bone-forming cells – osteoblast – in bone formation under the influence of vitamin D_3 . Bones are asymmetrical when first formed. Their unnecessary parts — are, therefore, dissolved by bone-eating cells called osteoclasts. This process also proceeds under the influence of parathormone. It results in release of calcium and phosphate in blood.

Vitamin D_3 , is a steroid hormone which is first synthesized in an inactive form in skin cells from 7-dehydrocholesterol under the influence of ultraviolet (UV) rays of sunlight. Skin cells release it in blood. Liver cells take it from blood, change in into 25-hydroxycholecalciferol and release back into blood. Finally, the cells of proximal convoluted tubules of nephrons in the kidneys change 25-hydroxycholecalciferol into 1-25-dihydroxycholecalciferol under the influence of parathormone. This last compound is released in blood as active vitamin D_3 named as cholecalciferol (calcitriol).

In addition to its role in bone-remodelling, D_3 also stimulates absorption of Ca^{2+} and Mg^{2+} in intestine. Similarly, parathormone also plays an additional role of stimulating excretion of Na^+ , K^+ and HCO^-_3 , but retarding the excretion of Mg^{2+} .

Irregularities of parathormones

(1) Hypoparathyroidism (Hyposecretion of parathormone)

- (i) It is rare, however, in undersecretion of parathormone, the level of calcium in ECF falls (hypocalcemia), and that of phosphates rises (hyperphosphatemia). This causes neuromuscular hyperexcitability, excessive perspiration, gooseflesh (raising of hairs and prickly sensation in skin), cooling of hands and feet, painful muscular spasms and convulsions, and trembling.
- (ii) Sometimes some skeletal muscles, usually of hands and feet, fail to relax after a contraction, and remain in "sustained contraction". This is called "Tetany". Tetany of laryngneal, thoracic, and phrenic muscles, which help in breathing, causes death, because the patient fails to breathe (asphyxia).
- (iii) Childhood hypoparathyroidism retards growth, particularly of bones, teeth, hair and brain. Vitamin D is administered to such children.

(2) Hyperparathyroidism (Hypersecretion of parathormone)

(i) **Osteoporosis**: Oversecretion of parathormone is rare and occurs usually due to overgrowth of one or more parathyroid glands. It causes demineralization of bones which, therefore, become soft, weak, distorted and fragile. This is called osteoporosis.

- (ii) Hypercalcemia: Simultaneously, due to a sharp rise in calcium level in blood and ECF (hypercalcemia) and a sharp fall in phosphate level (hypophosphatemia), muscles and nerves are weakened.
- (iii) **Hypercalciurea**: Calcium is excreted in urine (hypercalciurea), thirst increases owing to copius urination, appetite is lost, constipation and headache become common, and often, kidney stones are formed. The only treatment so far known is removal of extra part of the glands by operation.

Feedback control of secretion of parathormone and thyrocalcitonin: Secretion of these two hormones is continuously regulated by a direct negative feedback. As Ca^{2+} levels tends to fall, secretion of parathormone increases, but that of thyrocalcitonin decreases. Contrarily, the secretion of parathormone decreases and that of thyrocalcitonin increases when Ca^{2+} level tends to rise in blood.

Adrenal gland

Adrenal gland was first reported by Eustachius.

Origin and position: The adrenals are paired glands placed on the top or superior of the kidneys as cap. Hence, they are also called suprarenal glands.

Adrenals have a dual origin, they are originated from ectoderm and mesoderm both. Like thyroid, adrenals are also highly vascular in nature.

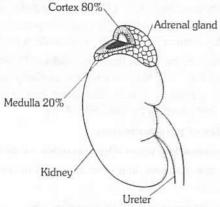

Fig: 5.7-13 Adrenal gland with a part cut to show cortex and medulla

Structure: Each adrenal is a small (5 cm long, 3 cm broad and 1 cm thick), triangular and yellowish cap like structure. Its weight in humans is about 3.5 to 5.09 gm. At birth adrenal glands are best developed. Each gland has two parts – outer cortex and inner medulla.

- (1) **Outer cortex:** The cortex is derived from mesoderm and forms about 80% part of the gland. Cortex consists of fatty, cholesterol rich cells. These cells distinguish the cortex into three zones or regions.
- (i) **Zona glomerulosa**: It is the outer part of the cortex (15% of the gland), which consists of small polyhedral cells. It secrets mineralocorticoids *e.g.*, Aldosterone.
- (ii) **Zona fasciculata**: It is the middle part of the cortex (50% of the gland). Which consists of large polyhedral cells. This part secrets gluco-corticoids. *e.g.*, Cortison, Corticosterone.

- (iii) **Zona Reticularis**: It is the inner part of the cortex (7% of the gland). In which the parallel cell cords of the zona fasciculata branched to form a loose anastomosing network. It secrets sex hormones.
- (2) Inner medulla: The medulla is derived from ectoderm and forms about 20% part of the gland. Adrenal medulla is reddish brown in colour and colourless of rounded groups of short cords of relatively large and granular cells. These cells are modified postganglionic cells of sympathetic nervous system. These are called chromaffin cells or phaeochromocytes. Adrenal medulla secrets adrenalin and nor-adrenalin which are collectively called as catecholamines.

Hormones of adrenal cortex

About 20 steroids (steroidogenic) compounds are secreted from adrenal cortex. These are called adrenocorticoids (corticosteroids). Only few of them are biologically active as hormone. These hormones are steroid in nature. The later, however account about 80% of the secretion of adrenal cortex and are classified into three categories.

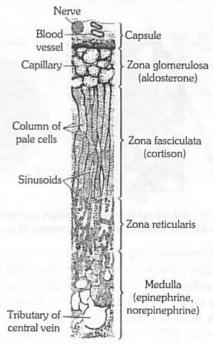

Fig: 5.7-14 Adrenal gland with a part cut to show cortex and medulla

(1) Mineralo-corticoids: The principal mineralocorticoid is aldosterone. It is also called salt-retaining hormone. It promotes reabsorption of sodium ions from kidney and excretion of potassium ions in urine. It also reabsorb Cl⁻ ions from kidney. Thus aldosterone has a important contribution in homeostasis by controling osmotic pressure of ECF (Extra cellular fluid).

Remember that doctors administer saline drip to the patients who lose excessive water and salts due to diarrhoea, cholera, etc. Aldosterone also helps in maintaining acid-base equilibrium and blood pH (7.35) by promoting reabsorption of HCO_3 and regulating excretion of H^+ by kidneys. It also promotes absorption of water and salt in intestine, mainly in colon. The Reninangiotensin-aldosterone or RAA pathway controls secretion of Aldosterone.

- (2) **Gluco-corticoids**: These include three main hormones cortisol, corticosterone and cortisone. Cortisol is most abundant (about 95%) and most important. These hormones play an important role in carbodydrate, fat and protein metabolism as follows –
- (i) Cortisol retards glucose consumption and protein synthesis, but promotes breakdown of proteins and fats in the cells.
- (ii) Effects of glucocorticoids upon liver are anabolic. These promote intake of glucose, FFAs and amino acids by cells of liver. Then, these intensify deamination of amino acids, synthesis of urea, synthesis of glucose from fatty acids and amino acids (gluconeogenesis), and synthesis of glycogen from glucose (glycogenesis) in liver cells.
- (iii) Cortisol is anti-inflammatory. It retards the migratory movements and phagocytic activities of white blood corpuscles (WBCs), suppressing "inflammation reactions" which constitute the normal defense mechanism of body against toxic substances. Simultaneously, it reduces the number of mast cells, reducing secretion of histamine. This is also an anti-inflammatory effect. It also denotes synthesis of collagen fibres which usually form at the sites of inflammation in normal defense. That is why, cortisol is usually injected as a drug for treatment of diseases that are caused by deposition of collagen fibres, such as arthritis or rheumatism.
- (iv) Cortisol is also "immunosuppressive". It suppresses synthesis of antibodies, retarding the normal immune reactions of body against antigens and attack of micro-organisms. In fact, it induces atrophy of thymus gland and other lymphoid tissues, so that the productions of lymphocytes is inhibited. That is why, it is used for treatment of allergy. Also, it is used in transplantation surgery to suppress the formation of antibodies in the body of recipients so that the latter may accept the transplanted organs.
- (v) Cortisol increases RBC count, but decreases the WBC count of blood. It also elevates blood pressure (BP).
- (3) Sex hormones: The zona reticularis of adrenal cortex secrets androgen and estrogen in small quantity. These hormones regulates the development of sex organs, secondary sexual characters and promote growth and protein metabolism.

Role of adrenal cortex in stress reaction: Adrenal glands provide the body with an emergent "chemical defence mechanism" in stress conditions that threaten the physical integrity and chemical consistency of the body. After the "Fight or Flight" reaction, the body remains in a state of shock for some time just like a country after a war. Heartbeat, cardiac output, blood pressure and glucose and salt concentrations in ECF considerably go down in this "shock condition". For example, excessive bleeding in an accidental injury immediately sends the body into shock condition, the injured must be made to recline and his / her legs must be elevated by putting a few pillows under the feet and hips. This increases venous flow of blood towards the heart, so that the cardiac output is maintained.

Whereas the hormones of adrenal medulla elevate O_{2-} consumption, BMR, respiration and tension to increase alertness and responsivity to prepare the body for violent stress-reactions, those of adrenal cortex, particularly aldosterone and cortisol, serve to maintain the body in living condition and recoup it from the

severe after-effects of stress reactions. An increased output of cortisol is actually "life-saving" in shock conditions. It inhibits the normal defence mechanisms and mobilises help from all parts of the body in order to keep the body alive.

Adrenal glands are large in fetus, but these mainly secrete sex hormones. By the time of child-birth, these become small and their secretions remain minimal for a few days after birth. Obviously, the "chemical defence system" is very weak in newly born infants. The latter can, therefore, easily succumb to stress conditions. That is why, infants are provided extra care in maternity homes.

As is clear from above account, adrenal cortex is very necessary for survival, but adrenal medulla is not so necessary, because its deficiency can be compensated by sympathetic nervous system.

Control of adrenal cortex secretions: Secretion of glucocorticoids and sex hormones by adrenal cortex is regulated by a hormone, corticotropin or adrenocorticotropic hormone (ACTH), secreted by the anterior lobe of pituitary gland. Secretion of ACTH from pituitary is, in turn, regulated by a "corticotropin-release hormone (ACTHRH)" of hypothalamus. A "feedback control mechanism" operates between hypothalamus, pituitary and adrenal cortex. A decrease in cortisol level in blood stimulates the hypothalamus and pituitary. Hence secretion of ACTHRH from hypothalamus and of ACTH from pituitary and, therefore, of glucocorticoids and sex hormones from adrenal cortex increases. When cortisol level in the blood rises, the control mechanism operates in reverse direction. This "feedback control" is very efficient and quick.

Secretion of mineralocorticoids is only nominally under the control of ACTH. Although adrenal glands themselves regulate secretion of mineralocorticoids according to Na⁺, water and K⁺ levels in ECF, by feedback, but this regulation is mainly provided by the kidneys. As the blood pressure goes down due to decreased amount of salt and water in blood, certain cells of afferent arterioles that supply glomeruli secrete an enzyme named renin.

Hormones of adrenal medulla

The chromaffin cells of adrenal medulla synthesize two hormones adrenalin or epinephrine (80%) and nor-adrenalin or nor-epinephrine (20%). These hormones are proteinaceous in nature and derived from amino acid tyrosine. Which is first hydroxylated and decarboxylated to form dopamine and than the latter is hydroxylated again to finally form norepinephrine. Epinephrine is derived by methylation of norepinephrine.

Nor epinephrine — Methylation — Epinephrine

Cortisol from adrenal cortex induce synthesis of enzymes needed to convert nor epinephrine to epinephrine. Norepinephrine lacks the converting enzymes. Because the ANS controls the chromaffin cells directly, hormones release can occur very quickly.

The molecular structure of dopamine, norepinephrine and epinephrine, includes a 6-carbon ring connected to two hydroxyl groups (– *OH*). This is called catechol ring, and these compounds are called catecholamines for this reason.

UNIVERSAL BOOK DEPOT 1960

1018 Chemical Co-ordination and Integration

Epinephrine (adrenalin) was first extracted by Abel (1899) who coined this name for it. It was, however, extracted in pure form by Jokichi and Takamine (1900). Its molecular structure was worked out by Aldrich in 1901. Stolz (1904) and Dakin (1905) synthesized it in their laboratories. Norepinephrine was discovered by Ulf von Euler (1946). Effects of these hormones were studied by Axelrod (1965). For their discoveries Euler and Axelrod won Nobel Prize in 1970.

Function of epinephrine

- (1) Epinephrine causes constriction of the blood vessels (vasoconstriction) which supply blood to those peripheral and abdominal organs (skin and organs of digestive, excretory and reproductive systems) that normally remain active while we are resting or sleeping. Obviously, the activities of these organs are retarded, but the blood pressure (BP) increases.
- (2) Reduced supply of blood causes a pale skin (pallor), but arrector pilli muscles of skin contract, causing gooseflesh.
 - (3) Mouth becomes dry due to poor secretion of saliva.
- (4) Food digestion is retarded because of reduced gut peristalsis due to relaxation of the smooth muscles of gut wall, as well as, because of poor secretion of digestive glands.
- (5) Kidneys produce small volume of urine, and muscles or urinary bladder relax.
- (6) In pregnant women, the muscles of uterus contract, increasing the possibility of abortion.
- (7) Epinephrine causes dilation of blood vessels (vasodilation) which supply brain, skeletal muscles, heart, lungs, liver, adipose tissues, sensory organs, etc. Due to increased blood supply, these organs become very active, inducing alarm reaction. Obviously, the blood pressure, increased due to effect of norepinephrine, is reduced to some extent.
- (8) Pupils dilate due to contraction of radial dilatory muscles of iris. Secretion of tear by lacrimal glands increases.
- (9) Epinephrine causes relaxation of the smooth muscles of trachea, bronchi and bronchioles. These organs, therefore dilate, so that breathing becomes easier and faster. Remember that epinephrine is used in treatment of asthma for this reason.
- (10) Contractions of cardiac muscles intensify, increasing both rate and force of heartbeat, pulse rate, arterial pressure and cardiac output.
- (11) Due to an increase in adhesiveness of blood platelets, the time of blood clotting is considerably reduced.
- (12) The spleen contracts, releasing its reserve of blood corpuscles whose number in blood, therefore, increases.
- (13) In islets of Langerhans in pancreas, secretion of insulin hormone decreases, but that of glucagon increases. Glucagon causes glycogenolysis, i.e. breakdown of glycogen into glucose in liver and skeletal muscles.
- (14) Because of an increase in blood levels of O_2 glucose, FFA, etc the basal metabolic rate of all body cells considerably increases and renders the whole body highly active and irritable.

(15) External genitalia become flaccid, but ejaculation becomes early and forceful.

Since the rate and force of the activities of most internal organs increase in a few seconds under the effects of epinephrine and norepinephrine, the various changes can be detected by a lie detector polygraph to ascertain the emotional state of a person.

Table : 5.7-9 Difference between Adrenal cortex and Adrenal medulla

S.No.	Adrenal cortex	Adrenal medulla	
1.	It is external firm region of the adrenal gland.	It is central soft region of the adrenal gland.	
2,	It is pale yellowish-pink in colour.	It is dark reddish-brown in colour.	
3.	It is enclosed by a fibrous capsule.	It is not enclosed by a fibrous capsule.	
4.	It forms about 80% of the adrenal gland.	It forms just 20% of the adrenal gland.	
5.	It develops from the mesoderm.	It develops from the ectoderm (neural crests).	
6.	It consists of 3 concentric regions : Outer zona glomerulosa, middle zona fasiculata and inner zona reticularis.	It is not differentiated into regions.	
7.	It is essential for life, its destruction causes death.	It is not essential for life, its destruction does not cause death.	
8.	It secretes 3 groups of hormones: mineralocorticoids, glucocorticoides and gonado corticoids	nor adrenaline and adrenaline	
9.	It is stimulated to release its hormones by the adrenocorticotrophic hormone from the anterior pituitray.	It is stimulated to secrete its hormones by nerve impulses reaching via sympathetic nerve fibres.	
10.	There is no cooperation between adrenal cortex and sympathetic nervous system.	Adrenal medulla and sympathetic nervous system function as an integrated system called sympatheticoadrenal system.	
11.	It causes many deficiency / excess disorders.	It is not known to cause any disorder.	

Significance of adrenal medullary hormones

Relationship between adrenal medulla and sympathetic nervous system: Our routine in voluntary activities like food digestion, respiration, heartbeat and blood circulation, thermoregulation, peristalsis of tubular organs, secretion of glands, excretion, etc are continuously and automatically done by our internal (visceral) organs without the conscious control of our brain. These are, therefore, called involuntary activities, these activities occur under the control of autonomic nervous system and their co-ordinated regulation is controlled by the hypothalamus of brain. The autonomic nervous system controls these activities by affecting the activity levels of

cardiac muscles, smooth muscles of visceral organs and blood vessels, and the glands. The autonomic nervous system comprises two control systems, having antagonistic effects of these organs. These are sympathetic and parasympathetic systems. Obviously, the motor nerve fibres of both these systems, originating from central nervous system (CNS), innervate most of the internal organs. The motor fibres of parasympathetic system stimulate those organs which remain more active while we are at rest or sleeping. contrarily, the motor fibres of sympathetic system stimulate those organs which remain more active when we are awake and doing work.

The fibres of sympathetic system, innervating the organs, the postganglionic motor fibres. At their terminals, these release norepinephrine, a neurotransmitter which triggers an alteration in the activities of concerned organs. The adrenal medulla is also innervated by fibres of sympathetic system, but these are preganglionic fibres of this system. At their terminals these fibres release acetylcholine which stimulates chromaffin cells to release their hormones - epinephrine and norepinephrine. Circulating in blood, these hormones reach into the internal organs and not only increase the effects of sympathetic stimulation, but also prolong these effects about ten-fold. That is why, the sympathetic system adrenal medulla are collectively considered as sympathoadrenal system, and the hormones of adrenal medulla are called sympathomimetic amines. Besides this, the medullary hormones, especially epinephrine, increase the basal metabolic rate (BMR) of all body cells, increasing the activity and irritability level of whole body. Since, however, the effects of sympathetic system and adrenal medullary hormones are complementary, a retarded efficiency of any one of these is compensated by the

Modern scientists have discovered that cells resembling chromaffin cells occur in small groups near the thoracic and abdominal ganglia of sympathetic system. These groups have been named paraganglia.

Alarm or stress reaction: Physico-chemical changes continuously occur in the external and internal environments of our body during our daily routine life, and our body keeps on maintaining homeostasis and functional equilibrium by counteracting the effects of these changes by alterations and coordinated regulations of the activities of various organs by sympathetic system under hypothalamic control. However, the emergency or stress conditions such as fear, anger, intense pain, accident and injury, burning, intense cooling or heating of body, sudden invasion of micro-organisms, poisoning, emotional upsets due to insult, restlessness, mental tension, anxiety, exertion, surgery, etc tend to disturb homeostasis and functional equilibrium to such an extent that the very survival of body in endangered.

As the sensory impulses of such strong stimuli called stressors, reach the brain, directly or through spinal cord, motor impulses or required responses are issued by hypothalamus to all organs, including adrenal medulla through the spinal cord. Consequently, norepinephrine is released simultaneously in all organs by sympathetic fibres, and a large amount of both epinephrine and norepinephrine is poured into blood by adrenal medulla. This

"mass release" of these hormones prepares the whole body, within seconds, for a violent physical reaction called alarm or stress reaction, and often referred to as general adaptation syndrome (GAS). In this reaction, the concerned person either boldly faces the emergency, or tries somehow to escape from it. That is why, it is called "Fight or Flight reaction".

Effects of irregularities of adrenal secretion

- (1) **Hyposecretion :** This may be a genetic defect. Undersecretion of adrenocorticoids (hypocorticism) causes Addison's disease which is relatively rare and occurs in both men and women between the ages of 20 to 40 years. This disease was first described by Thomas Addison in 1849, 1855. It is maintained in following symptoms :
- (i) Owing to low aldosterone and gluco-corticoides level in blood, considerable amount of sodium ions and water is excreted in urine, leading to dehydration, low blood pressure, and weakness, all symptoms of a peculiar, Addinosonean anaemia which is different from common pernicious anaemia resulting from entirely different causes like diarrhoea, cholera, etc.
- (ii) Owing to low cortisol level, glucose level also falls in blood (hypoglycemia). This sharply reduces BMR in body cells. Due to hypoglycemia and hyperkalemia (increased K^+ level in blood) efficiency of brain, liver, skeletal and cardiac muscles, etc declines. Body temperature also falls. Heartbeat may even stop, causing death.
- (iii) Decreased cortisol level induces gastro-intestinal disorders, resulting in loss of appetite, nausea, vomiting, diarrhoea, abdominal pain and restlessness.
- (iv) Due to a sharp decline in body's chemical defense and resistance, sensitivity to cold, heat, infection, poisoning and other adverse condition increases. Acute hypocorticism is catastrophic and threatens life. Complete destruction or removal of adrenals causes death in a short time, principally because of loss of excessive sodium in urine.
- (v) Addison's disease also causes an increase in the number of WBCs, resulting into eosinophilia, lymphocytosis, leucocytosis, etc.
- (vi) Undersecretion of sex hormones causes impotence in males and disorders of menstrual cycle in females.
- (vii) Excessive deposists of melanin, particularly in the skin of open parts of body like face, hands, feet, neck, teats, etc cause deep bronzing of skin in these parts.
- (viii) As increase in H^+ concentration in blood may cause acidosis.
- (2) Hypersecretion : Oversecretion of adrenocorticoids (hypercorticism) causes following disorders and diseases –
- (i) Glucose level rises in blood (hyperglycemia). This may lead to diabetes mellitus.
- (ii) Irregular deposits of fat, particularly in thoracic parts and face, imparts asymmetrical shape to the body. the face becomes red and rounded (moon face), shoulders swell (buffalo humps) and abdomen dilates and often shows lines of stretching. All these are

symptoms of Cushing's disease (Cushing, 1932). Patients may die from brain haemorrhage, cardiac arrest, pneumonia, etc.

- (iii) Retention of sodium and water is the ECF increases blood pressure, causing severe hypertension and associated symptoms like severe headache.
- (iv) Excessive loss of potassium in urine causes potassium deficiency (hypokalemia). This leads to muscular weakness and convulsions and nervous disorders, and may even cause tetany and paralysis, copious and frequent urination (polyuria) and thirst, bed urination (nocturia), etc. Similarly, excessive loss of H^+ in urine may cause alkalosis.

Fig: 5.7-15 A girl showing pseudohermaphroditism

- (v) Excessive mobilization of materials from all parts of body had widespread deteriorating effects. For instance, mobilization of proteins from all cells causes tissue wasting, similarly, mobilization from bones renders the bones weak and fragile (osteoporosis).
- (3) Excessive secretion of male hormones (androgens) in a female fetus before complete formation of ovaries results into pseudohermaphroditism due to masculinization of external genitals, and causes abnormal development of muscles, hair on face (beard and moustache), early sexual maturation, hoarse voice and absence of menstruation. The clitoris grows to penis size, while vagina and uterus remain underdeveloped. This is known as adrenogenital syndrome. The resultant females are sterile. Oversecretion of androgens after complete formation of ovaries and fallopian tubes causes only a moderate enlargement of clitoris. Oversecretion of androgens in girls after birth causes a gradual masculinization manifested in overgrowth of clitoris, under development of mammary glands and uterus and disturbed menstruation. Oversecretion of androgens in male children causes excessive development of penis (marcogenitosomia) and other secondary sexual organs and characteristics, but atrophy of testes so that there is no spermatogenesis. Early erections are noted. Due to the anabolic effects of androgens, both in girls and boys, growth is accelerated, muscles are well-developed and strong, and bones mature early.
- (4) Excessive secretion of female hormones in adult males cause enlarged mammary glands (gynaecomastia) and retards growth of beard. Contrarily, excessive secretion of androgens in females in masculinizing and causes hirsutism (increased facial and body hair and muscle growth, clitorial enlargement, etc.)

Pancreas

Location and origin : Pancreas (Gr. pankreas = sweet bread; Fr., pan = all + kreas = flesh) is a flattened and pinkish mixed gland (both exocrine and endocrine) situated in the concavity formed by duodenum just behind the stomach. It measures about 15 cm in length and 4 to 5 cm in breadth. It forms by fusion of two bilateral endodermal processes of embyronic intestine (duodenum of future adult).

Structure: About 99% part of the gland is exocrine and formed of hollow pancreatic acini or lobules embedded in a connective tissue stroma. In the stroma, there are numerous (approximately 1 to 2 million in human pancreas) small (0.1 to 0.2 mm in diameter) clusters of endocrine cells, called islets of Langerhans after the name of their discoverer, Paul Langerhans (1869).

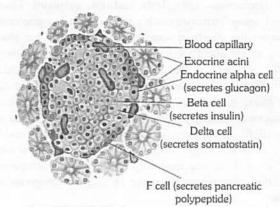

Fig: 5.7-16 T.S. of pancreas

Cells Types in the Pancreatic Islets

Each pancreatic islet includes four types of hormone-secreting cells:

- (1) **Alpha or A cells** constitute about 15% of pancreatic islet cells and secrete glucagon.
- (2) **Beta or B cells** constitute about 80% of pancreatic islet cells and secrete insulin.
- (3) **Delta or D cells**: It's constitute about 5% of pancreatic islet cells and secrete somatostatin (identical to growth hormone-inhibiting hormone secreted by the hypothalamus).
- (4) **F cells**: It's constitute the remainder of pancreatic islet cells and secrete **pancreatic polypeptide**.

Hormones of pancreas and their role

The β and α cells of islets of Langerhans respectively secrete insulin and glucagon hormones which are important regulation of carbohydrate, protein and fat metabolism in the body.

(1) **Insulin**: In 1889, Minkowski and Mehring discovered that pancreas is related with the disease of diabetes mellitus in humans. Normal concentration of glucose in blood is about 100 mg (0.1 gm) per 100 ml. It increases somewhat after a

carbohydrate rich food. Then, the secretion of insulin increases. It increases the permeability of all cells for glucose several times, except that of brain cells and red blood corpuscles (RBCs). The brain cells and RBCs are already highly permeable to glucose. After taking more glucose from blood, the cells utilize it for energy-production. Consequently, the basal metabolic rate (BMR) and RNA and protein synthesis increases in cells.

In 1923, two Canadian scientists, Banting and Best succeeded in preparing a pure extract of insulin from the pancreatic islets of a new born calf with the help of Macleod, Banting and Macleod won the 1923 Nobel prize for this work. Later, Abel (1926) succeeded in preparing pure crystals of insulin. F. Sanger (1955) worked out the molecular structure of bovine insulin and won the 1958 Nobel Prize. He discovered that insulin is a small protein whose molecule consists of two polypeptide chains, α and β , joined by disulphide linkages and respectively formed of 21 and 30 amino acid residues. Insulin is the first protein to be crystallized in pure form, first protein whose molecular structure was worked out, the first protein to be synthesized in laboratory in 1964, and also the first protein to be commercially manufactured by means of DNA recombinant technique. Even the human insulin was also synthesized by Tsan in 1965.

(i) **Hypoinsulinism**: In insulin deficiency, body cells fail to obtain glucose from blood. Hence, glucose level of blood rises, a condition called hyperglycemia. When glucose level rises further, glucose starts passing out in urine. This condition is called glycosuria. Ultimately, when glucose level in blood rises to more than 200 mg/100 ml blood the person concerned suffers from diabetes mellitus in which the urine becomes sweet.

Diabetes mellitus has been known to Greeks as a human disease since 1500 B.C. in England, it was known as a "pissing evil" due to copious urination in it. Modern scientists have discovered that diabetes mellitus is of two types - I and II. The type I diabetes is usually found in young people, in some of which it is hereditary. About 10% of diabetic patients suffer from this type. Other patients suffer from diabetes of type II, usually found in people of over 40 years of age or obese persons. Diabetics excrete large volumes of urine. This is called polyuria. It results into dehydration which, in turn, causes increased thirst (polydipsia) and hunger (polyphagia). Being unable to utilize glucose for energyproduction ("starving in midst of plenty"), the cells utilize their proteins for it, causing "body wasting". The body, therefore, becomes very weak. Nervous system may be damaged and often cataract occurs. Lipolysis in adipose tissues increases, elevating blood level of free fatty acids (FFA). Accelerated, but incomplete, oxidation of fatty acids for energy, especially in liver, results into the formation of ketone bodies - acetone, acetoacetic acid and βhydroxybutyrate-, causing ketosis. Since the ketone bodies are sweet, acidic and poisonous, their increased amount in blood causes acidosis. Hence, patients may anytime become unconscious (coma condition) and finally die.

Regular injections of insulin must be given to chronic patients of diabetes. Balanced diet, exercise, and regular intake of insulin tablets (eg dionyl) may keep diabetes in control. Certain drugs, like glyburide, which stimulate insulin secretion are now available.

- (ii) Hyperinsulinism: Oversecretion of insulin enhances glucose intake by most body cells and glycogenesis in liver and muscles, causing a persistent decrease in blood glucose level (Hypoglycemia) since brain cells and cells of retina and germinal epithelium mainly depend on glucose for energy, nervous efficiency, fertility and vision sharply decline. Poor supply of glucose to the brain stimulates sympathetic nervous system, causing unnecessary excitement and feeling of anxiety, sweating, weakness, fatigue and muscular convulsions. Continued excess of insulin in blood causes "coma (insulin shock)" and death. Injections of cortisol, adrenaline, growth hormone and glucagon help in treatment of hyperinsulinism, because these hormones retard glucose utilization in cells and mobilize glucose and fatty acids respectively from liver and adipose tissues. Injections of glucose also give relief to the patients.
- (2) Glucagon: This is secreted by the alpha cells of islets of Langerhans. It was discovered by Kimball and Murlin (1923). Like insulin, it is also a small protein. Its molecule consists of a single polypeptide chain of 29 amino acid residues. Its function is to elevate glucose level in blood when glucose is deficient. For this, glucagon intensifies glycogenolysis, deamination and gluconeogenesis, and inhibits glycogenesis in liver cells. It also intensifies lipolysis in adipose tissues. Thus, it is a promoter of catabolic metabolism. When, during excessive physical labour and stress, glucose consumption in the body increases and blood glucose level falls, glucagon is secreted to normalize the glucose level.

The secretion of insulin and glucagon is regulated by a "limit-control feedback" or "push and pull feedback" control system. When sugar level in blood increases, insulin is secreted and secretion of glucagon is inhibited. When, due to the effect of insulin, blood sugar level falls, secretion of insulin is inhibited and that of glucagon is stimulated.

(3) Somatostatin and Pancreatic polypeptide: Modern physiologists have postulated that the δ and F (PP) cells of pancreas respectively secrete somatostatin (SS) and pancreatic polypeptide (PP). Somatostatin resembles the growth hormone inhibitory hormone (GHIH) secreted by hypothalamus. Its molecule is a small peptide of 14 amino acid residues. Acting as a paracrine hormone, it serves to retard secretory activities of α and β cells. Besides this, it also slows down food digestion, absorption of digested nutrients and assimilation of nutrients in cells. Thus, it prolongs utilization of every feed. pancreatic polypeptide (PP) also acts as a local, paracrine hormone. It retards secretion of pancreatic enzymes and somatostatin. It also inhibits motility of stomach, duodenum and gall bladder.

Table: 5.7-10 Difference between diabetes mellitus and diabetes insipidus

S.No.	Diabetes mellitus	Diabetes insipidus
1.	It is due to deficiency of insulin.	It is due to deficiency of ADH.
2.	The blood sugar becomes high and glucose appears in urine.	The blood glucose is normal and glucose does not appear in urine.
3.	There is high blood cholesterol and ketone body formation.	There is no such phenomenon.

Thymus gland

Origin and position: The thymus is bilobed gland, is located in the upper part of the thorax near the heart in the mediastinum. It is endodermal in origin, arising in the embryo from the epithelium of outer part of third branchial pouches.

Structure: Structurally, it is like lymph gland enveloped by a thin, loose and fibrous connective tissue capsule. Septa, or trabeculae extending inwards from the capsule, divide the two lobes of the gland into a number of small lobules. Each lobule is distinguished into a cortical parenchyma containing numerous lymphocytes, and a medullary mass of large, irregularly branched and interconnected epithelial cells (reticular cells), a few lymphocytes and some phagocytic cells called macrophages or Hassal's corpuscles.

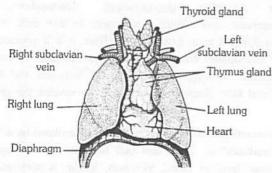

Fig: 5.7-17 Location of thymus gland

Function of thymus glands

- (1) Thymus is haemopoietic, as well as, an endocrine gland. Thymus is the "seedbed" of "thymic lymphocytes (T-lymphocytes). Certain "stem cells", originating in yolk sac and liver in early embryo, but only in bone marrow in late embryo, migrate into the thymus and proliferate to form a large number of lymphocytes.
- (2) The major function of thymus is to secrete thymosin hormone, thymic humoral factor (THF), thymic factor (TF), thymopoietin. These compounds induce, not only the proliferation of lymphocytes, but also their differentiation into a variety of clones differently specialized to destroy different specific categories of antigens and pathogens likely to get into the body. This is called maturation of lymphocytes.
- (3) As is clear from above account, thymus is essential in neonatal (newly born) infant and postnatal child for normal development of lymphoid organs and cellular immunity. That is

why, the thymus, small at birth, progressively grows in size about three or four-folds upto about the age of puberty. By this time lymphoid organs and tissues are well-developed. The thymus, therefore, starts gradually diminishing in size and its tissue is progressively infiltrated by yellowish adipose tissue. This is known as the "immunity theory of ageing". By the old age, the thymus is reduced to quite a thin, yet functional chord of tissue.

Pineal gland (Epiphysis)

Origin, position and structure: This is a small, whitish and somewhat flattened ectodermal gland situated at the tip of a small, fibrous stalk that arises from dorsal wall of diencephalon, i.e. the roof (epithalamus) of third ventricle of the brain. Due to its location, it is also called epiphysis cerebri. It is covered over by a thin capsule formed of the piamater of the brain. Septa from this membrane extend into the gland, dividing in into lobules having two types of branched cells, viz the large and modified nerve cells, called pinealocytes, and interstitial or neuroglial cells forming the supporting tissue. The pineal gland starts degenerating after the age of about 7 years because of deposition of granules of calcium salts (brain sand) in it.

Function of pineal body: Hormone, though the function of the gland is still the subject of current research, it is known to secrete one hormone, melatonin. Melatonin concentration in the blood appears to flow a diurnal (day-night) cycle as it arises in the evening and through the night and drops to a low around noon. Melatonin lightens skin colour in certain animals and regulates working of gonads (testes and ovaries). Light falling on the retina of the eye decreases melatonin production, darkness stimulates melatonin synthesis. Girls blind from birth attain puberty earlier than normal, apparently because there is no inhibitory effect of melatonin on ovarian function.

Serotonin, a neurotransmitter found in other locations in the brain, is also found in the pineal gland. Research evidence is accumulating to support the idea that the pineal gland may be involved in regulating cyclic phenomena in the body. Melatonin also is a potent antioxidant. Melatonin causes atrophy of gonads in several animals.

Gonads

The gonads are the sex glands, the testes and the ovary. Testes is the male gonad and ovary is the female gonads. Besides producing gametes, the gonads secrete sex hormones from the onset of puberty (sexual maturity) to control the reproductive organs and sexual behaviour.

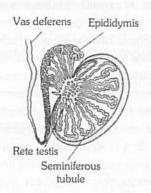

The sex hormone were discovered by Adolf Butenononal in 1929 and 1931. He won the 1939 Nobel prize jointly with Leopold Ruzicka.

Testes

Location and structure: In testes between the siminiferous tubules, special types of cells are present called interstitial cells or cells of leydig. These cells secrete male hormones (androgens) derived from cholesterol. The main androgen is testosterone other less important androgens include androstenedione and

UNIVERSAL BOOK DEPOT 1960

dehydroepiandrosterone (DHEA). It is a masculinizing hormone. From puberty to the age of about twenty year *i.e.* adolescence or the period of sexual maturation or attainment of adult hood.

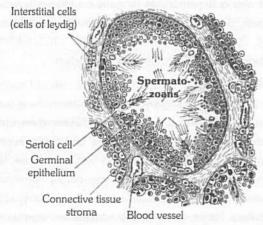

Fig: 5.7-18 Ultrastructure of testes

Function

- (1) It stimulates the male reproductive system to grow to full size and become functional.
- (2) It stimulates the formation of sperms (spermatogenesis) in the seminiferous tubules.
- (3) It stimulates the development of male accessory sex characters such as hair on the face (beard and moustaches), growth and distribution of hair on the body, thickening of skin, deepening of voice, enlargement of larynx, broadening of shoulders, narrow lips enlarged and stronger bones and muscles. It also maintains these characters.
- (4) It also determines the male sexual behaviour sexual urge, aggressive behaviour.
- (5) Under its effect protein anabolism increases. (This function is obvious in the heavier muscle and bone mass of most men as compared to women).
 - (6) Grythropoisis in bone marrow increases.
- (7) In brief, testosterone determines libido or sex drive. It is also required, together with the follicle stimulating hormone (FSH) of pituitary, for initiation and completion of spermatogenesis. All androgens are also secreted in traces from adrenal glands in both boys and girls.
 - (8) Increased sebaceous gland secretion.

Development of testis: Under the effect of chorionic gonadotropic hormone, secreted by placenta during pregnancy, the testes of eight to nine months old fetus start secreting testosterone. The latter regulates differentiation and development of urinogenital system, accessory genital organs and external genitalia in the embryo. During childhood *i.e.* from birth to puberty (age of 11 to 13 years), testes remain quiescent, so that androgens are not secreted. At puberty, the gonadotropic hormones (FSH and ICSH) of pituitary reactivate the testes which, therefore, start producing sperms and resume secreting androgens. Upto the age of about 40 years, androgens are secreted in sufficient amounts. thereafter, their secretion starts gradually declining, but the capability of reproduction still continues for many years.

Castration: Surgical removal of testes is called castration or orchidectomy. Castration, or deficient secretion of testosterone (hypogonadism) before puberty (due to congenital defects or injury to testes) retards growth of genitalia, muscles and bones, as well as, the development of sexual characteristics.

Castration or hypogonadism after puberty preserves the libido, but diminishes its overall efficiency (demasculinization). Muscular strength, hair growth, spermatogenesis, sex urge and potency sharply decline. Sometimes, the person becomes impotent.

Castration is widely used in animal husbandry and domestication. Castrated cattle, horses and fowls are respectively called steers, geldings and capons. Castration makes these docile.

Ovaru

Primordial ovarian follicles are formed in the primitive ovaries of female fetuses as early as about 16 weeks of gestation, but these do not secrete hormones. Even in early childhood, upto the age of 7 or 8 years, ovaries remain quiescent. Thereafter, the pituitary starts secreting gonadotropins (FSH and LH) under whose influence puberty in girls sets in at about the age of 11 to 13 years; ovaries become active and menstrual cycle begins, so that the girls attain sexual maturity. Reproductive period, i.e., ovarian function and menstrual cycles in women normally cease at about the age of 45 to 55 years. This is called menopause. It usually results in a rise in urinary excretion of gonadotropins of the pituitary gland.

Ovarian hormone: Under the influence of FSH and LH. They secretes three female sex hormone, estrogen, progesteron and relaxin. They are derived from cholesterol.

(1) **Oestrogen**: These are secreted by the cells of the Graffian (ovarian) follicle surrounding the maturing ovum in the ovary. They stimulate the female reproductive tract to grow to full size and become functional. They also stimulate the differentiation of ova (oogenesis) in the ovary. They also stimulate the development of accessory sex characters such as enlargement of breasts; broadening of pelvis; growth of pubic and axillary hair; deposition of fat in the thighs, and onset of menstruation cycle. Graffian follicle cells are stimulated to secrete oestrogens by luteinising hormone (LH) from the anterior lobe of the pituitary gland. Rise of blood-oestrogens level above normal inhibits the secretion of LH from the anterior pituitary. This negative feedback prevents the oversecretion of oestrogens.

(2) **Progesterone**: It is secreted by the corpus luteum. The latter is a yellowish body formed in the empty Graffian follicle after the release of the ovum. Its hormone suspends ovulation during pregnancy, fixes the foetus to the uterine wall, forms placenta, and controls the development of the foetus in the uterus. Progesterone is also called anti-abortion hormone. Ovulation, formation of corpus luteum and secretion of progesterone are stir julated by the luteinising hormone (LH) from the anterior pituitary.

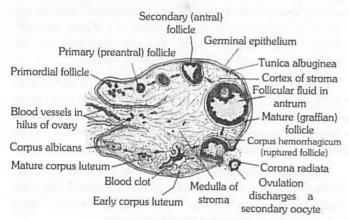

Fig: 5.7-19 V.L.S. of ovary

(3) Relaxin: It is produced by the corpus luteum at the end of the gestation period. It relaxes the cervix of the uterus and ligaments of the pelvic girdle for easy birth of the young one.

Regulation of ovarian hormone: Secretion of estrogens is regulated by the gonadotropins of pituitary. Undersecretion of estrogens (hypogonadism) before puberty due to congenital defects or damage to ovaries, causes female eunuchoidism. Accessory genitals and breasts remain underdeveloped, pelvis remains narrow and buttocks flat. Secondary sexual characteristics also do not develop. Hypogonadism in adulthood reduces fertility and disturbs menstrual cycles. Oversecretion (hypersecretion of hypergonadism) of estrogens also disturbs menstrual cycles and may even cause cancer.

Gravidex test: Involve testing of hcG of placenta in the urine to test the pregnancy.

Contraceptive pills: Contain less oestrogens and more progesterone so called combined pills. These check ovulation and so pregnancy in female.

Adiposogenital syndrome: Also called hypothalmic eunuchoidism characterized by hypogonadism in male caused by genetic inability of hypothalamus to secrete gonadotrophin releasing hormones.

Hormonal Contraception

Female contraception: As already described, gonads are stimulated to produces sex cells (gametes) and secrete sex hormones by the gonadotropic hormones (FSH and LH) of anterior pituitary. The anterior pituitary is, in turn, stimulated to secrete gonadotropins by the gonadotropin-releasing hormone

(GnRH) of hypothalamus. In women, FSH promotes oogenesis and secretion of female hormones (estrogens). LH promotes ovulation, formation of corpus luteum and secretion of progesterone from it. A negative feedback regulation operates between GnRH and gonadotropins, on one hand, and between gonadotropins and female hormones on the other. Hence, high concentration of female hormones retards secretion of FSH, LH and GnRH due to which oogenesis does not occur, and pregnancy is out of question. Contraceptive pills of mixtures of estrogens and progesterone are more effective. The most popular contraceptive pills contain synthetic ethinyl estradiol and synthetic progesterone (e.g. norethindrone). In a modern method, a capsule of synthetic progesterone, like levonor gestrel, is implanted under the skin. The capsule serves for contraception for about five years.

Abortion is also now permissible in many countries to check population growth. Since progesterone is necessary to maintain early pregnancy, drugs, like mifepristone (RU-486), which inhibit the effects of progesterone are administered for abortion.

Male contraception: In men, LH stimulates cells of Leydig to secrete male hormones (androgens) of which testosterone is the principal hormone. Testosterone, in turn, inhibits LH secretion, but not FSH secretion by anterior pituitary. FSH and testosterone stimulate spermatogenesis. It has been found that large doses of testosterone can inhibit secretion of gonadotropin-release hormone (GnRH) by thalamic cells, thereby inhibiting secretion of both LH and FSH by pituitary. Hence systematically administered injections of testosterone have been suggested as a means of male contraception.

Recently, the cells of Sertoli in seminiferous have been found to secrete a protein factor named inhibin which directly inhibits secretion of FSH by pituitary. Hence, use of inhibin as a male contraceptive is now being explored.

Gastro-intestinal mucosa, placenta, skin, kidney and heart

- (1) Gastro-intestinal mucosa: Inner most layer of the wall of the alimentary canal is called mucosa. Certain cell of the mucosa of the stomach and intestine secrete important hormones. Gastrointestinal mucosa is endodermal in origin.
- (i) **Stomach**: The mucosa of the pyloric stomach near the duodenum secretes a hormone called gastrin. Presence of food in the stomach provides a stimulus for gastrin secretion. Gastrin stimulates the gastric glands to produce the gastric juice. It also stimulates the stomach movements.
- (ii) Intestine: The intestinal mucosa secretes six hormones: secretin, cholecystokinin, enterogastrone, enterocrinin, duocrinin and villikinin. Entry of acidic food from the stomach into the duodenum serves as a stimulus for the release of these hormones.

- (a) Secretin: It is produced by the small intestinal mucosa. It causes the release of sodium bicarbonate solution from the pancreas for pancreatic juice and from the liver for bile. It also inhibits the secretion and movements of stomach.
- (b) Cholecystokinin-pancreozymin (CCK-PZ): This hormone is secreted by the mucosa of entire small intestine. The actions of cholecystokinin and pancreozymin were discovered independently. But it has been discovered that both hormones have similar effects and hence it is considered one hormone. As the name suggest CCK-PZ has two main functions. The word cholecystokinin is derived from three roots: Chol meaning bile, Cyst meaning bladder, and kinin meaning to remove. The word pancreozymin is derived from pancreas and Zymin, which means enzyme producer. This hormone stimulates the gall bladder to release the bile and also stimulates the pancreas to release its enzymes.
- (c) Enterogastrone: It is secreted by the duodenal mucosa. It shows gastric contractions and stops the secretion of gastric juice.
- (d) Enterocrinin: It is secreted by duodenal mucosa. It stimulates crypts of Lieberkuhn to secrete the enzymes in the intestinal juice.
- (e) Duocrinin: It is secreted by the duodenal mucosa. It stimulates the release of viscous mucus from Brunner's glands into the intestinal juice.
- (f) Villikinin: It is secreted by the mucosa of the entire small intestine. It accelerates the movements of villi to quicken absorption of food.
- (2) Placenta: When the early embryo reaches into the uterus from fallopian tube, it becomes implanted with uterine wall by a placenta for support and nutrition. The cells of placenta secrete two steroid hormones (estradiol and progesterone) and two protein hormones (human chorionic gonadotropin-hcG and human chorionic somato mammotrophin-HCS). Early placenta secretes so much of chorionic gonadotropin that the latter starts being excreted in mother's urine just after about two weeks of pregnancy. Its presence in urine is used for pregnancy test. It serves to maintain the corpus luteum, and to stimulate it for secretion. Due to its effect, the corpus luteum continues secreting oestrogens, progesterone and relaxin. It also serves to maintain pregnancy by preventing contraction of uterine wall. After about three months of pregnancy, secretion of progesterone by the placenta increases. Hence, importance of corpus luteum decreases, and it starts degenerating. If therefore, ovaries are surgically removed at this stage, pregnancy remains unaffected, i.e. there is no abortion and the fetus grows and develops normally.

The chorionic somatomammotropin was formerly known as placental lactogen. Reaching into mother's body, its serves as a mid growth hormone and promote growth of milk glands.

Relaxin hormone: This hormone has been obtained from corpus luteum of ovaries and from the placenta. It is a polypeptide.

During pregnancy it causes relaxation of the ligaments of pubic symphysis, and towards the termination of pregnancy, softens and widens the opening (cervix) of uterus for easy child birth (parturition). A temporary structure with endocrine function is placenta.

- (3) **Skin**: Vitamins of D group are synthesized in skin cells under the effect of ultraviolet (UV) rays of sunlight from cholesterol-derived compounds. Cholecalciferol (D_3) is the main D vitamin. It circulates in blood. Liver cells convert it into hydroxycholecalciferol (calcidiol) by hydroxylation and release back into blood. Certain cells of proximal convoluted tubules of nephrons in the kidneys convert calcidiol into dihydroxycalciferol (calcitriol) by further hydroxylation and release back into blood. Calcitriol is an important regulator of Ca^{2+} homeostasis. It promotes absorption of Ca^{2+} and phosphorus in intestine and bone-formation. It is therefore, required for growth of body and bone healing. Its deficiency in childhood causes thin, weak and curved bones, a condition called rickets. Its deficiency after growth period, causes weak, porous and fragile bones. This is called osteomalacia.
- (4) Kidney: Whenever the rate of ultrafiltration in kidneys decreases due to low blood pressure (BP), the cells of juxtamedullary complexes secrete into blood a compound named renin. The latter is a proteolytic enzyme. It acts upon a large plasma-protein formed in liver and called angiotensinogen, separating a small protein from it called angiotensin-I. Besides their function of excretion, the kidneys secrete three hormones, viz calcitriol, renin and erythropoietin. Calcitriol is the active form of vitamin D_3 as already described. While the blood flows in blood capillaries of liver, an angiotensin-converting enzyme (ACE) converts angiotensin-I into angiotensin-II which acts as a hormone. This hormone accelerates heartbeat and constricts arterioles increasing blood pressure. Consequently, the rate of ultrafiltration increases. Simultaneously, it stimulates adrenal cortex to secrete aldosterone, and enhances water and sodium reabsorption from nephrons. These factors also increase the volume of ECF, elevating blood pressure.

Erythropoietin (EPO) controls formation of erythrocytes (red blood corpuscles-RBC's) in red bone marrow. That is why, its secretion increases on decrease in blood volume, or RBC count, or haemoglobin deficiency (anaemia). Hence EPO is also called renal erythropoietic factor. Contrarily, its secretion decreases when RBC count tends to increase due to blood transfusion or other reasons.

(5) **Heart**: When volume of ECF and blood pressure (BP) increase due to retention of more *NaCl* in the body, certain cardiac muscle cells of the atria of heart secrete an atrial natriuretic peptide (ANP) which acts as a hormone. The effect of ANP is to promote copious urination (diuresis) and excretion of *NaCl* (natriuresis) to normalise ECF volume and BP. It also inhibits the effect of vasoconstrictor hormones and secretion of renin, aldosterone and vasopressin hormones.

Table: 5.7-11 List of hormones, their chemical nature and functions

S.No.	Name of endocrine gland	Name of hormone and its chemical nature	Functions
1.	Neurosecretory cells of Hypothalamus (Supraoptic Nucleus and Paraventricular Nucleus)	Oxytocin and vasopressin monopeptide Gonadotropin releasing hormones Other releasing hormones e.g. TSHRH, MSHRH,	Milk ejection and parturition (oxytocic effect). Vasoconstriction and antidiuretic (vasotocin) effects. Stimulates FSH and LH synthesis Stimulate TSH, MSH, ACTH GH secretions
		ACTHRH, GHRH etc. Proteinaceous	from pituitary.
2.	Pituitary (a) Neurohypophysis (Pars Nervosa) (b) Adenohypophysis (contains diverse cell types)	Store and release Oxytocin and Vasopressin. Proteinaceous or glycoprotein	Hormone release is related to physiological state and requirements. Affect growth, development differential pubertal changes and other metabolic mechanism.
3.	Pineal	Melatonin-derived from the amino acid tyrosine	Antagonist to FSH / LH Regulates biological / circadian rhythms.
4.	Thyroid gland (amine hormone) having – NH ₂ group)	 (a) Thyroxine, iodinated amino acid called tyrosine (T₂, T₃, T₄). (b) Thyrocalcitonin (Peptide) 	 (a) Controls basal metabolic rate (BMR). All organ / system of body responds to thyroxine. (b) Facilitates Ca⁺² absorption
5.	Parathyroid gland	Parathormone, Peptide	Ca+2 and PO-4 metabolism.
6.	Thymus	Thymosine (polypeptide)	Anti-FSH and LH; delays puberty
7.	Islets of lengerhans (= Endocrine pancrease) (i) α-cells (ii) β-cells (iii) δ-cells	Glucagon Isolated by Insulin Banting Secretin Polypeptide	(i) Gluconeogenesis / Glycogenolysis (ii) Glycogenesis (iii) Gastric functions
8.	Adrenal gland (a) Adrenal medulla (Amine hormone have – NH ₂) (b) Adrenal cortex	(a) Catecholamines (epinephrine = adrenaline, and norepinephrine = noradrenaline (derived from tyrosine) (b) Mineralocorticoids and glucocorticoids and	Stresses = emergency = Fright, Fight and Flight Hormone (3F) accelerates cardiac functions muscle activity etc. (b) Electrolyte and carbohydrate metabolism.
	(o) Find that correct	traces of androgen and oestrogen steroids derived from cholesterol	
9.	Ovary (a) Granulosa cells steroid, fat soluble have sterol group derived from cholesterol	Oestrogen (Steroid) oestrone, oestradiol	(a) Secondary sex character primary action on uterine endometrium mitogenic.
	(b) Corpus luteum	Oestrogen and Progesterone (Steroid)	(a) Secreted during luteal phase of menstrual cycle in human female and oestrous cycle of other mammals. Prepares uterine endometrium for receiving blastocyst for implantation. Progesterone is also called pregnancy hormone and is anti-FSH and anti-LH/anti-LTH.
	Placenta temporary endocrine gland formed during pregnancy	(a) Steroid secreted are estrogen and progesterone (b) Relaxin-Polypeptide	(a) Maintenance of pregnant state, prevents lactogenesis folliculogenesis, and Ovulation. (b) Act on pubic symphysis and enlarges the birth canal to facilitate birth. Acts synergestically with oxytocin during this process (parturition)
10.	Testis (i) Sertoli cells (= sustentacular cells) (ii) Leydig cells (=Interstitial cells)	(i) Inhibin – Polypeptide (ii) Oestradiol-Steroid Androgens (e.g. Testosterone) Steroid androstenedione)	Inhibits FHS action and attenuates spermatogenesis decrementally (i) Pubertal changes in male, (ii) Secondary sex characters in male, (iii) Sex drives, (iv) Spermatogenesis
11.	Gastro-intestinal hormones (secreted by cells of mucosa of stomach and intestine) also called hormones (a) Pyloric stomach (Argentophil cells) Intestine	Gastrin (i) Secretin (ii) Cholecystokinin (CCK) (iii) Enterogastrone (iv) Duocrinin (v) Enterokinin (vi) Villikrinin	Stimulates gastric juices secretion from gastric gland, movement of sphincters of stomach and increased movement of stomach (i) Stimulates secretion of succus entericus, (ii) Bile released from gall bladder, (iii) Inhibits gastric secretion, (iv) Stimulates secretion of mucous from Brunner's gland, (v) Stimulate intestinal gland, (vi) Stimulate villi movement

Table: 5.7-12 Disease caused by hormonal irregularities

Disease	Hormone	Quantity	Gland
Dwarfism	GH	Deficiency	Pituitary
Gigantism	GH	Excess	Pituitary
Acromegaly	GH	Excess	Pituitary
Simmond's disease	GH	Deficiency	Pituitary
Diabetes incipidus	ADH	Deficiency	Pituitary
Cretinism	Thyroxine	Deficiency	Thyroid
Simple goitre	Thyroxine	Deficiency	Thyroid
Myxoedema	Thyroxine	Deficiency	Thyroid
Exophthalamic goitre	Thyroxine	Excess	Thyroid
Tetani	Parathormone	Deficiency	Parathyroid
Plummer's disease	Thyroxine	Excess	Thyroid
Addison's disease	Mineralocorticoids (Aldosterone) and Glucocorticoids (cortisol)	Deficiency	Adrenal cortex
Conn's disease	Mineralocorticoids	Excess	Adrenal cortex
Cushing's disease	Corticosteroid	Excess	Adrenal cortex

Local hormones, pheromones and insect endocrine glands

Local hormones

Hormones described so far are called circulating hormones, because these circulate in whole body with blood. When stimulated by physical or chemical stimuli, all body cells, except red blood corpuscles (RBCs), secrete certain such compounds which transmit coded informations of metabolic adjustments between neighbouring cells and hence remain ECF instead of diffusing into the blood. These compounds are called local tissue hormones or autocoids. These are short-lived, because various enzymes present in ECF continue degrading these at a fast rate.

Local hormones are of two main categories-paracrine and autocrine. Paracrine hormones affect metabolism of cells located in the neighbourhood of those which secrete them. Autocrine hormones affect metabolism of the every cells which secrete them. Most local hormones are paracrine. These belong to the following categories:

- (1) **Eicosanoids**: These are a category of lipids derived from fatty acid, arachidonic acid, synthesized in the plasma membrane of cells, and released in ECF. These are of four categories, *viz*. Prostaglandins, prostacyclins, thromboxanes and leukotrienes.
- (i) **Prostaglandins** (**PGs**): In 1935, Ulf von Euler discovered that human semen contains a very active compound presumably secreted by prostate gland and, hence, named as such. He found that after the semen is discharged in woman's vagina, this compound contracts uterine muscles to facilitate the sperms to ascend into fallopian tubes and reach ova to fertilize these.
- (ii) Prostacyclins: These are found in walls of blood vessels and induce vasodilation. These also facilitate flow of blood in vessels and prevent thrombosis by inhibiting aggregation of platelets.
- (iii) Thromboxanes: These are secreted by blood platelets. These help in blood clotting by instigating aggregation of platelets

at the place of injury. These also instigate vasoconstriction at places of injury to prevent excessive loss of blood.

- (iv) **Leukotrienes**: These are secreted by eosinophils of blood and mast cells of connective tissues. These serve as mediators in inflammatory and allergic reactions, induce bronchoconstriction (constriction of bronchioles), constrict arterioles and induce migration of neutrophils and eosinophils towards the places of inflammation. These can cause asthma, arthritis, colitis, etc.
- (2) Neuroregulators: These are a category of proteins which function as paracrine hormones in nervous tissues. These can be classified in three categories as follows:
- (i) **Neurotransmitters**: These are synthesized in nerve cells and are secreted by exocytosis by axon terminals of these cells. These serve to transmit nerve impulses from one neuron to other neighbouring neuron, or muscles, or glands across synapses. About 60 of these have so far been discovered, but the most common of these are acetylcholine, norepinephrine, dopamine, serotonin and histamine.
- (ii) **Neuromodulators**: In nervous tissues, the neurons secrete such paracrine hormones which modulate (increase or decrease) the excitability of other neighbouring neurons. These hormones are called neuromodulators. The main positive neuromodulators which increase the excitability of other neurons are the amino acids glutamate and aspartate, and polypeptide named 'P' substance. Contrarily, the main negative modulators which decrease the excitability of neighbouring neurons are the amino acid glycine and gama aminobutyric acid (GABA), polypeptides named enkephalins, endorphins, dynorphins and tachychinins, and the nitric oxide (NO).
- (iii) Nerve growth factors: The supporting glial cells of nervous tissues and cells of muscles, salivary glands and many other tissues secrete such polypeptide paracrine hormones which play important role in growth, development and survival of nerve cells. That is why, these hormones are collectively called neurotrophins.

Pheromones

These are defined as chemicals excreted or released by one animal to the exterior, but evoke a physiological or behavioral response in another animal of the same species. Some pheromones, release on body surface, evoke a response in the recipient when tasted by the latter by licking, but most pheromones are volatile and odorous fatty acids (hydrocarbons) whose air borne molecules are received by recipient animals through olfaction. Certain insect pheromones are well-known examples. For instance, certain insects secrete bombykol or gyplure to attract their mating partners. Some other insects release geranoil to transmit information of food, source of danger to their fellows.

In mammals, presumably including humans, certain volatile fatty acids secreted in vaginal fluid by females acts as pheromones. These may evoke sex drive in males, or affect menstrual cycle in other females. It has been observed that there is a tendency of synchronized menstrual cycles in female roommates. This "dormitory effect" must be due to pheromones.

Table: 5.7-13 Types of pheromones

S.No.	Туре	Example
1.	Sex pheromones	Bombycol – Silkmoth (female) Queen substance – Honey bee (Queen Civetone – Cat Muskone – Muskdeer
2.	Aggregation pheromones	Geradiol – Honey bee
3.	Alarm pheromones	Danger signals
4.	Marking pheromones	Mark the territory in wild animals

Insect endocrine glands

The endocrine system of cockroach comprises intercerebral gland cells, corpora cardiaca, corpora allata, and prothoracic glands.

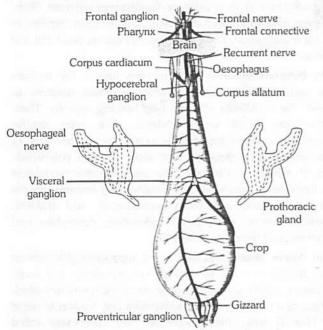

Fig: 5.7-20 Endocrine glands of cockroach

- (1) Intercerebral gland cells: These cells lie in the brain between the two cerebral ganglia. They secrete a hormone called the brain hormone. This hormone activates the prothoracic glands to secrete their hormone.
- (2) Corpora cardiaca: These are a pair of rod-like bodies situated on the sides of the oesophagus just behind the brain. They secrete a growth hormone.
- (3) Corpora Allata: These are a pair of small, rounded bodies lying close behind the corpora cardiaca. They secrete a juvenile hormone in the nymphal stages. This hormone causes retention of the nymphal characters and checks the appearance of adult characters. In other words, it keep the insect young. In the last nymphal form, corpora allata become inactive, thereby resulting in the absence of juvenile hormone. The absence of this hormone permits the appearance of adult features. In the adult, the corpora allata again become active and secrete a gonadotropic hormone, which regulates egg production and development and functioning of the accessory sex glands.
- (4) Prothoracic glands: These are fairly large, irregular glands situated in the prothorax. They secrete a hormone called ecdyson, which controls moulting of the nymphs. The prothoracic glands degenerate after metamorphosis.

- The word 'endocrine' is derived from a Greek word meaning 'I separate within'.
- The word 'hormone' was first used in reference to secretin.
- The father of endocrinolgy is Thomas Addison. The first endocrine disease reported was Addison's disease (1855) caused by the destruction of adrenal cortex or glucocorticoids.
- When two hormones work against each other to control a process, this is called antagonism, e.g., Insulin and Glucagon, Calcitonin and Parathormone.

- ✓ Protein hormones act at membrane level and change the permeability of plasma membrane.
- Steroid hormones enter nucleus and inactivate or activate the function of some gene.
- Although thyroxine is not a steroid hormone but it is lipid soluble and acts at gene level like steroid hormones.
- Water soluble hormones act through extracellular receptors.

- Lipid soluble hormones act through intracellular receptors.
- Insulin receptor is a heterotetrameric protein consisting of 2α subunits and 2β subunits.
- © One signaling molecules activates many mediators and one molecule of mediator activates hundreds of other molecules. In this way a signal is amplified hundred folds.

- Secondary messengers are intermediate compounds that amplify a hormonal signal.
- By using two opposite signals within a cell sympathetic and parasympathetic nervous system achieve opposite actions.
- Cells have receptors for insulin and glucagons which also have antagonistic effects.
- Although thyroxine is not a steroid hormone but it is lipid soluble and acts at gene level like steroid hormones.
- E Endocrine glands with ducts are pancreas, ovaries and testes.
- Primary target organ of hypothalamus is pituitary gland.
- In amphibians and reptiles pineal gland is considered third vestigeal eye.
- ✓ In human pituitary, the intermediate lobe is functional in embryo but is rudimentary in adult.
- One neuron-one hormone hypothesis is followed by pituicytes.
- Sometimes Growth hormone is the only hormone of anterior pituitary that has direct effect on body cells.
- Median eminence is a part of posterior pituitary.
- Myesthenia gravis : Abnormal neuromuscular excitation due to hypersecretion of thymosine.
- # Hormones are also called autocoids or chemical messengers or information molecules.
- ∠ Local hormones are also called para-hormones or tissue hormones.
- First discovered hormone was secretin but first isolated hormone was insulin and was isolated from pancreas of dogs by Banting and McLeod.
- Thyroxine hormone is derived from tyrosine amino acid while oxytocin and ADH are short chain peptide hormones.
- Pheromones: These are intra-specific chemical messengers released by an animal into air to initiate specific response in another animal of same species. These may be signals of food, mate etc. These are also called ectohormones. Term pheromone was coined by Karlson and Butendant (1959).

- ✓ Feedback inhibition: In this, end product sends certain
 inhibitory signals (called negative feedback) when end product
 is at required level.
- **Endocrinologist**: Scientist involved in the study of endocrine glands.
- Ecdysone: A steroid hormone secreted by prothoracic glands present in the prothorax of insects the cockroach and controls moulting or ecdysis.
- **Solution** Juvenile hormone: Secreted by a pair of rounded endocrine glands called corpora allata, present just behind corpora cardiaca. These secrete juvenile hormone in the nymphal stage and checks the appearance of adult characters.
- ∠ Level of hormones in our blood can be measured by Radio Immune Assay (RIA).
- Hormone receptors are always proteinous and are located either on cell membrane of target cells or in cytosol.
- Spleen does not secrete any hormone.
- Basal metabolic rate (BMR) minimum energy required during rest or sleep (160 Kcal/day).
- Thyroid gland is only endocrine gland that stores its secretory product.
- ∠ During continuous stress size of adrenal gland (mainly adrenal cortex) increases.
- Human insulin was prepared for the first time byTsan in 1965.
- Insulin is effective only when it is given by injection.
- If insulin is taken orally, it is digested.
- E Chemicals, alloxan and streptozotocin selectively destroy beta cells of islets of Langerhans.
- Cobalt chloride selectively destroys alpha cells of islets of Langerhans.
- Humulin: Genetically engineered human insulin is called humulin.
- Acidosis: Decrease in pH of blood e.g. in diabetes mellitus.
- The seminal vesicles are the chief source of prostaglandins in semen.
- The commonest prostaglandins are PGA₁, PGA₂, PGE₁, PGE₂ PGF.

Objective Questions

Hormones and their mechanism

1. The name second messenger is given to

[NCERT; MP PMT 2002]

Or

In the mechanism of action of a protein hormone, one of the second messengers is [NCERT]

- (a) ATP
- (b) Cyclic AMP
- (c) GTP
- (d) Both ATP and AMP
- In mechanism of hormone action, which of the following is not a second messenger [MHCET 2015]
 - (a) Cyclic AMP
- (b) IP₃
- (c) Ca++
- (d) Mg+

3. What is hormone

[MP PMT 1998]

- (a) Glandular secretion
- (b) Enzyme
- (c) Chemical messenger
- (d) Organic complex substance
- 4.shows anti-allergic and anti-inflammatory effect

[GUJCET 2015]

- (a) Mineralocorticoids
- (b) Glucocorticoids
- (c) Sexcorticoids
- (d) Noradrenaline
- 5. Which is the inhibitory hormone of GH [GUJCET 2015]
 - (a) Insulin
- (b) Parathormone
- (c) Somatostatin
- (d) Testosterone
- 6. The chemical nature of hormones secreted by $\alpha \& \beta$ cells of pancreas is [WB JEE 2009]
 - (a) Glycolipid
- (b) Glycoprotein
- (c) Steroid
- (d) Polypeptide
- 7. Which of the following cell does not secrete hormone

[MP PMT 2000]

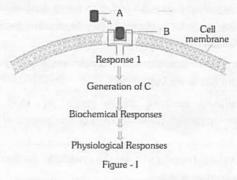

- (a) Kupffer cell
- (b) Leydig cell
- (c) Lutein cell
- (d) Parafollicular cells of thyroid
- **8.** Which of the following hormones are produced in the hypothalamus and stored in the posterior pituitary

[KCET 2006]

[MP PMT 2000]

- (a) FSH and LH
- (b) ADH and oxytocin
- (c) TSH and STH
- (d) ACTH and MSH
- Which of the following is not necessarily a property of all hormones [AIIMS 1993]
 - (a) Information carrying
- (b) Secreted in low amounts
- (c) Short half-life
- (d) Protein in nature
- 10. The feed back control mechanism is related with
 - [CBSE PMT 2000; BHU 2002]
 - (a) Bile secretion
- (b) HCl secretion
- (c) Hormonal secretion
- (d) Hering breuer reflex
- 11. Pheromone is(a) A product of endocrine gland
 - (b) Used for animal communication
 - (c) Messenger RNA
 - (d) Always protein

12. Consider the given diagrammatic representation of the mechanism of action for 2 categories of hormones. In which of the following option correct answers for blanks A to I are indicated [NCERT]

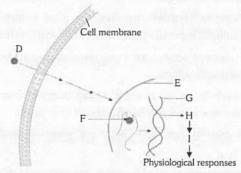

Figure - II

- (a) A Steroid hormone, B Enzyme, C Secondary messenger, D - Non- steroid hormone, E - Nucleus, F -Hormone - enzyme complex, G - Genome, H - mRNA, I - protein
- (b) A Steroid hormone, B Receptor, C Primary messenger, D - Non- steroid hormone, E - Nucleus, F -Hormone- receptor complex, G - Genome, H - mRNA, I - protein
- (c) A Non -Steroid hormone, B Receptor, C Secondary messenger, D - Steroid hormone, E - Nucleus, F -Hormone receptor complex, G - Genome, H - mRNA, I - Protein
- (d) A Steroid hormone, B Receptor, C Secondary messenger, D - Non- steroid hormone, E - Nucleus, F -Hormone - receptor complex, G - Genome, H - mRNA, I - protein
- 13. Who is the "Father of Endocrinology"

[CPMT 2000; BHU 2006]

- (a) Whittaker
- (b) Einthoven
- (c) Pasteur
- (d) T. Addison
- 14. Term 'hormone' was coined by
- [CPMT 1994]
- (a) W. M. Bayliss
- (b) E. H. Schally
- (c) E. H. Starling
- (d) G. W. Harris

(c) Parathyroid and Adrenal (d) Pancreas and parathyroid

UNIVERSAL BOOK DEPOT 1960

Receptors for protein hormones are located What is correct to say about the hormone action in humans (a) In cytoplasm (b) On cell surface [CBSE PMT (Pre.) 2012] (a) Glucagon is secreted by β -cells of Islets of Langerhans (c) In nucleus (d) On endoplasmic reticulum 16. Which one of the following flows directly into blood from and stimulates glycogenolysis (b) Secretion of thymosins is stimulated with aging the seat of its production to act on an organ away from it In females, FSH first binds with specific receptors on (a) Enzyme (b) Hormone (Renin) ovarian cell membrane (c) Blood (d) Lymph (d) FSH stimulates the secretion of estrogen 17. Which is not involved as 2nd messenger in Ca+2 mediated progesterone hormone [NCERT; DPMT 2007] Which is a 32 amino acid water soluble peptide hormone (a) c-AMP (b) DAG [AMU (Med.) 2010] (c) Phospholipase (d) IP2 (a) Gastrin (b) Calcitonin 18. Hormones may be [BVP 2003; CBSE PMT 2004] (c) Glucagon (d) Insulin (a) Amino acid derivatives (b) Peptides 5. A health disorder that results from the deficiency of (c) Steroids (d) All the above thyroxine in adults and characterized by (i) a low metabolic 19. Which of the following statements is correct in relation to rate, (ii) increase in body weight and (iii) tendency to retain the endocrine system [NEET 2013] water in tissues is [CBSE PMT 2009] (a) Releasing and inhibitory hormones are produced by the Or pituitary gland Man with thick lips, dirt deposited on tongue, low heart (b) Adenohypophysis is under direct neural regulation of beating rate, with excess amount of cholesterol in blood, is the hypothalamus supposed to be suffering from which abnormality (c) Organs in the body like gastrointestinal tract, heart, [CPMT 1996] kidney and liver do not produce any hormones (a) Hypothyroidism (b) Simple goitre (d) Non-nutrient chemicals produced by the body in trace (c) Myxoedema (d) Cretinism amount that act as intercellular messenger are known as One of the following cells secretes a hormone[MHCET 2015] hormones (a) Cells of Leydig (b) Cells of Sertoli 20. Endocrine glands [NCERT; J & K CET 2002: (c) Primary spermatocyte (d) Secondary spermatocyte Odisha JEE 2012] Which one of the following hormones is not involved in (a) Do not possess ducts sugar metabolism [AIPMT 2015] (b) Sometimes do not have ducts (a) Aldosterone (b) Insulin (c) Pour their secretion into blood through ducts (c) Glucagon (d) Cortisone (d) Always have ducts 8. The hormones of posterior pituitary are oxytocin and 21. According to the accepted concept of hormone action, if vasopressin; but later is better known as [CPMT 2009] receptor molecules are removed from target organs (a) Antidiuretic hormone (b) Growth hormone [CBSE PMT 1995; AFMC 1999] (c) Corticotrophic hormone (d) Neurohypophyseal (a) The target organ will continue to respond to the Which one of the following four glands is correctly matched hormone without any difference with the accompanying description (b) The target organ will continue to respond to the [AIIMS 2008] hormone but will require higher concentration (a) Thyroid Hyperactivity in young children (c) The target organ will not respond to the hormone causes cretinism The target organ will continue to respond to the (b) Thymus Starts undergoing atrophy after hormone but in the opposite way puberty 22. All functions of the body are regulated and integrated by (c) Parathyroid Secretes parathormone, which promotes move-ment of calcium [MP PMT 1994, 96] ions from blood into bones during (a) Respiratory system (b) Digestive system classification (c) Neuroendocrine system (d) Excretory system (d) Pancreas Delta cells of the islets of Different glands and their hormones Langerhans secrete a hormone, which stimulates glycolysis in liver Select the mismatch pair from the following [KCET 2015] The hormone that maintains the secretory activity of the (a) Oxytocin - Contraction of uterine muscles corpus luteum as well as the increase in the size of the mammary glands is (b) Insulin - Gluconeogenesis (a) Estrogen (b) Luteinizing (c) Prolactin - Milk production in mammary glands (c) Luteotrophin (d) Gonadotrophin (d) Glucagon - Glycogenolysis 11. Which one of the following pairs of organs includes only the 2. Inadequate production of STH in early life may result in endocrine glands [CBSE PMT 2008] (a) Gigantism (b) Acromegaly (a) Thymus and Testes (b) Adrenal and Ovary

(c) Sterility

(d) Dwarfism

Secretion of the androgen by Leydig cells of testis is under the regulatory influence of [KCET 2004] (a) LTH (b) FSH (c) STH (d) ICSH The process of spermatogenesis and sperm formation is 13. under the regulatory influence of (b) ADH (c) LH 14. In human adult females oxytocin [MH CET 2005; CBSE PMT 2008] (a) Stimulates pituitary to secrete vasopressin (b) Causes strong uterine contractions during parturition (c) Is secreted by anterior pituitary (d) Stimulates growth of mammary glands 15. Which hormone stops the release of FSH from the pituitary after fertilization [CMC Vellore 1993; MP PMT 2009] (a) Placental hormone (b) Fertilizin (c) Estradiol (d) Luteinizing hormone 16. Diabetes insipidus is caused due to the deficiency of [AIIMS 1993; MP PMT 1997, 2003; CPMT 1999] (a) Oxytocin (b) Insulin (c) Vasopressin (d) Glucagon 17. A person suffering from diabetes insipidus will pass what amount of urine per day [MP PMT 1993] (b) $\frac{1}{2}$ litre (a) 1 litre (c) 3 litres (d) 1.5 litres 18. Which one of the following hormones through synthesized elsewhere is stored and released by the master gland [AIPMT 2015] (a) Luteinizing hormone (b) Prolactin (c) Melanocyte stimulating hormone (d) Antidiuretic hormone 19. The blood calcium level is lowered by the deficiency of [CBSE PMT 2008] Or The harmone that increases the blood calcium level and decreases its excretion by kidney is [DUMET 2009; WB JEE 2011] Tetany (Irregular muscle contraction) and osteoporosis are caused due to the deficiency of [MP PMT 1999, 2001; JIPMER 2002; WB JEE 2011; Kerala PMT 2012] (a) Both calcitonin and parathormone (b) Calcitonin (c) Parathormone (d) Thuroxine The activity of adrenal cortex is governed by a pituitary 20. hormone abbreviated as [DPMT 1993] Or Addison's disease is caused by under secretion of [DPMT 1993]

(b) FSH

(a) HCG

(c) ACTH (d) TSH

- Which one of the following pairs of hormones are the examples of those that can easily pass through the cell membrane of the target cell and bind to a receptor inside it (Mostly in the nucleus) [CBSE PMT (Pre.) 2012] (a) Insulin, glucagon (b) Thyroxin, insulin
- (c) Somatostatin, oxytocin (d) Cortisol, testosterone 22. The intermediate lobe of the pituitary gland produces a secretion which causes a dramatic darkening of the skin of many fishes, amphibians and reptiles. It is

[CBSE PMT 1993; Pb. PMT 1999]

Which of the following pituitary hormone is a direct action [MP PMT 2003]

- (a) Adrenocorticotropic hormone (ACTH)
- (b) Follicle stimulating hormone (FSH)
- (c) Melanocyte stimulating hormone (MSH)
- (d) Luteinizing hormone (LH)
- 23. The Leydig cells as found in the human body are the secretory source of [NCERT; MH CET 2007; CBSE PMT (Pre.) 2012]
 - (a) Progesterone (b) Intestinal mucus (c) Glucagon (d) Androgens
- Serotonin and Melatonin are hormones, secreted by

[MHCET 2015]

(a) Pancreas

(b) Pineal body

(c) Pituitary gland

(d) Thymus

25. Select the correct matching of a hormone, its source and ICBSE PMT (Mains) 20101

	Hormone	Source	Function
(a)	Vasopressin	Posterior Pituitary	Increases loss of water through urine
(b)	Norepinephrine	Adrenal medulla	Increases heart beat, rate of respiration and alertness
(c)	Glucagon	Beta-cells of Islets of langerhans	Stimulates glycogenolysis
(d)	Prolactin	Posterior Pituitary	Regulates growth of mammary glands and milk formation in females

- Pineal gland of human brain secretes melatonin concerned [RPMT 2005; MP PMT 2012; PET (Pharmacy) 2013]
 - (a) Anger

(b) Body temperature

(c) Colouration of skin

(d) Sleep

Endemic goiter is a state of

[WB JEE 2010]

- (a) Increased thyroid function
 - (b) Normal thyroid function
 - (c) Decreased thyroid function
 - (d) Moderate thyroid function

ш	
и	UNIVERSAL
н	BOOK DEPOT 1960

28. The anterior lobe of	f pituitary affects
--------------------------	---------------------

- (a) Protein metabolism
- (b) Fat metabolism
- (c) Carbohydrate metabolism
- (d) All of the above

29. Complete failure of adenohypophysis of pituitary causes

- (a) Addison's disease
- (b) Cushing's disease
- (c) Dwarfism
- (d) Simmond's disease
- **30.** A chemical signal that has both endocrine and neural roles is [AIPMT (Cancelled) 2015]
 - (a) Calcitonin
- (b) Epinephrine
- (c) Cortisol
- (d) Melatonin
- 31. A substance called ADH is

[CBSE PMT 1991]

- (a) A hormone that promotes glycogenesis in liver cells
- (b) An enzyme secreted by cell of intestinal wall; hydrolyses dipeptides into amino acids
- (c) A pituitary secretion which promotes reabsorption of water from glomerular filtrate
- (d) A high energy compound involved in muscle contraction
- The co-ordinator between Nervous and endocrine system is [MHCET 2015]

Or

Oxytocin is synthesized in

[WB JEE 2016]

- (a) Thalamus
- (b) Hypothalamus
- (c) Epithalamus
- (d) Colliculus
- 33. Growth hormone activity

[CPMT 1993]

- (a) Decreases with thyroxine (b) Increases with thyroxine
- (c) Remains same
- (d) None of these
- 34. Pituitary gland is found in
- [MP PMT 1994, 98]

- (a) Brain
- (b) Trachea
- (c) Gonads
- (d) Pancreas
- 35. A person entering an empty room suddenly finds a snake right in front on opening the door. Which one of the following is likely to happen in his neuro-hormonal control system [CBSE PMT (Pre.) 2012]
 - (a) Sympathetic nervous system is activated releasing epinephrin and norepinephrin from adrenal medulla
 - (b) Neurotransmitters diffuse rapidly across the cleft and transmit a nerve impulse
 - (c) Hypothalamus activates the parasympathetic division of brain ,
 - (d) Sympathetic nervous system is activated releasing epinephrin and norepinephrin from adrenal cortex

36. FSH is a

[RPMT 2000]

- (a) Catecholamine
- (b) Glycoprotein
- (c) Polypeptide
- (d) Steroid

37. Match List I with List II and select the correct option

	List I	List II				
Α.	Adrenalin	1.	Myxoedema			
B.	Hyperparathyroidism	2.	Accelerates heard beat			
C.	Oxytocin	3.	Salt-water balance			
D.	Hypothyroidism	4.	Childbirth			
E.	Aldosterone	5.	Demineralisation			

[DPMT 2006; Kerala PMT 2008; CPMT 2010]

- (a) A-2, B-5, C-4, D-1, E-3
- (b) A-3, B-4, C-5, D-3, E-2
- (c) A-5, B-3, C-2, D-4, E-1
- (d) A-2, B-3, C-4, D-5, E-1
- (e) A-5, B-3, C-4, D-2, E-1
- 38. Gonadotrophic hormones are produced in the

[MP PMT 1995; CBSE PMT 1999; CPMT 2010]

- (a) Posterior part of thyroid
- (b) Adrenal cortex
- (c) Adenohypophysis of pituitary
- (d) Interstitial cells of testis
- 39. Injury localized to the hypothalamus would most likely disrupt [CBSE PMT 2014]
 - (a) Executive function, such as decision making
 - (b) Regulation of body temperature
 - (c) Short term memory
 - (d) Co-ordination during locomotion
- 40. Adrenaline is equivalent to which neurotransmitter

[Odisha JEE 2009]

- (a) GABA
- (b) Serotonin
- (c) Epinephrine
- (d) Norepinephrine
- 41. Steroid hormones easily pass through the plasma membrane by simple diffusion because they [DUMET 2009]
 - (a) Are water soluble
 - (b) Contain carbon and hydrogen
 - (c) Enter through pores
 - (d) Are lipid soluble
- 42. If the pituitary gland of an adult rat is surgically removed, which of the following endocrine gland will be less affected

[DUMET 2009]

- (a) Adrenal cortex
- (b) Adrenal medulla
- (c) Thyroid
- (d) Gonads
- Select the correct option describing gonadotropin activity in a normal pregnant female [CBSE PMT 2014]
 - (a) High level of hCG stimulates the synthesis of estrogen and progesterone
 - (b) High level of hCG stimulates the thickening of endometrium
 - (c) High level of FSH and LH stimulates the thickening of endometrium
 - (d) High level of FSH and LH facilitate implantation of the embryo

- 44. Estrogen and testosterone are steroid hormones, and are most likely bind to [Odisha JEE 2009; DUMET 2009; KCET 2011]
 - (a) Membrane ions channels
 - (b) Enzyme-linked membrane receptors
 - (c) G-protein linked membrane receptors
 - (d) Cytoplasmic receptors
- 45. Which of the following secretes leutenizing hormone

[CPMT 1995]

- (a) Pituitary
- (b) Thyroid
- (c) Parathyroid
- (d) Adrenal
- 46. Pitressin is also called as

[CPMT 1995]

- (a) ADH
- (b) LH
- (c) NADH
- (d) FSH
- **47.** Which of the following hormones regulates growth and metamorphosis in insects [DUMET 2009]
 - (a) Juvenile hormone
 - (b) Brain hormone
 - (c) Ecdyson
 - (d) Prothoracicotropic hormone
- 48. Depict the correct site of hormone

[NCERT; RPMT 1995; DPMT 2007]

- (a) α glucagon, β insulin, δ somatostatin
- (b) α insulin, β glucagon, δ somatostatin
- (c) δ insulin, α somatostatin, β glucagon
- (d) α somatostatin, β insulin, δ glucagon
- 49. Glycosuria is the condition, where a man

[DUMET 2009; WB JEE 2010]

- (a) Eats more sugar
- (b) Excretes sugar in urine
- (c) Sugar is excreted in faeces
- (d) Has low sugar level in blood
- 50. Cortisol is secreted by the adrenal cortex in response to stress. In addition to its function in a stress response, it functions in negative feedback by [J & K CET 2012]
 - (a) Inhibiting the hypothalamus so that corticotropin releasing hormone (CRH) secretion is reduced
 - (b) Inhibiting the anterior pituitary's ability to respond to CRH by reducing the pituitary's sensitivity to CRH
 - (c) Both (a) and (b) are correct
 - (d) None of these
- 51. RAAS secretes which of the following hormone

[NCERT; DPMT 2007]

- (a) Mineralocorticoids
- (b) Glucocorticoids
- (c) Both (a) and (b)
- (d) None of these
- 52. Which one controls the secretion of oestrogen

[MP PMT 1997]

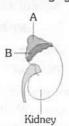

- (a) hCG
- (b) Progesteron
- (c) LH
- (d) FSH
- 53. Which one of the following is not a second messenger in hormone action [CBSE PMT 2006; WB JEE 2011]
 - (a) Sodium
- (b) cAMP
- (c) cGMP
- (d) Calcium

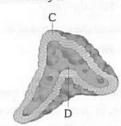

54. Fight-or-flight reactions cause activation of

INCERT: CBSE PMT 2014

- (a) The adrenal medulla, leading to increased secretion of epinephrine and norepinephrine
- (b) The pancreas leading to a reduction in the blood sugar levels
- (c) The parathyroid glands, leading to increased metabolic rate
- (d) The kidney, leading to suppression of reninangiotensinaldosterone pathway
- 55. At cellular level GH affects growth by controlling the production of [MP PMT 2000, 06]
 - (a) r-RNA
- (b) t-RNA
- (c) m-RNA
- (d) None of the above
- **56.** The synthesis of vasopressin is done by [RPMT 2001]
 - (a) Hypothalamus
- (b) Kidney
- (c) Anterior pituitary
- (d) Posterior pituitary
- 57. A person passes much urine and drinks much water but his blood glucose level is normal. This condition may be the result of [AIIMS 2003]
 - (a) A reduction in insulin secretion from pancreas
 - (b) A reduction in vasopressin secretion from posterior pituitary
 - (c) A fall in the glucose concentration in urine
 - (d) An increase in secretion of glucagon
- **58.** A man is admitted to a hospital. He is suffering from an abnormally low body temperature, loss of appetite and extreme thirst. His brain scan would probably show a tumor in [KCET 2009]
 - (a) Medulla oblongata
- (b) Pons
- (c) Cerebellum
- (d) Hypothalamus
- 59. See the following figures and identify it

[NCERT]

- (a) A Adrenal gland, B Fat, C Pars distalis, D Pars intermedia
- (b) A Adrenal gland, B Fat, C Medulla, D Cortex
- (c) A JGA, B Fat, C Cortex, D Medulla
- (d) A Adrenal gland, B Fat, C Cortex, D Medulla
- Thyrotropin-Releasing Factor (TRF) is produced by [MP PMT 2002]
 - (a) Cerebrum
- (b) Optic lobe
- (c) Cerebellum
- (d) Hypothalamus
- Similarity between the secretion of thyroid and adrenal is that both the secretions [AIIMS 1992]
 - (a) Are proteins
 - (b) Are steroid
 - (c) Increase glucose metabolism
 - (d) Control mineral metabolism

- 62. Calcitonin lowers the calcium level in the blood. This is secreted [CBSE PMT 1992; CPMT 1998; MP PMT 2013]
 - (a) Parathyroid
- (b) Hypothalamus
- (c) Adrenal
- (d) Thyroid
- Select the incorrect statement
- [NEET (Phase-I) 2016]
- (a) FSH stimulates the sertoli cells which help in spermiogenesis
- (b) LH triggers ovulation in ovary
- (c) LH and FSH decrease gradually during the follicular
- (d) LH triggers secretion of androgens from the leydig cells
- Disease caused by deficiency of iodine is 64.

[CBSE PMT 1993; MP PMT 1999; HP PMT 2005; MH CET 2007]

- (a) Goitre
- (b) Myxodema
- (c) Cretinism
- (d) Tetany
- 65. Which disease is caused by the deficiency of thyroxin in the adults [Pb. PMT 2000; MP PMT 2000]
 - (a) Diabetes incipidus
- (b) Diabetes mellitus
- (c) Myxoedema
- (d) Exopthalmic goitre
- Acromegaly results after adolescence due to excess production of one of the following hormones

[MP PMT 2001; AIIMS 2001; CBSE PMT 2002; Kerala CET 20021

- (a) Prolactin
- (b) Thyroxin
- (c) Insulin
- (d) STH
- 67. An organ X has a large blood supply. It produces a hormone lack of which causes a disease called as cretenism. The cause is [NCERT]

Cretinism is due to

[CPMT 1992, 93, 2004;

MP PMT 1993, 99; 2013; CMC Vellore 1993; WB JEE 2011]

- (a) Excess growth hormone
- (b) Absence of insulin
- (c) Excess adrenalin
- (d) Hyposecretion of thyroid in childhood (Thyroxin)
- 68. 'Exophthalmic goitre' (Grave's disease) is caused due to

[NEET (Phase-II) 2016]

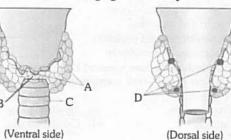

- (a) Hypofunction of the thyroid
- (b) Hyperfunction of the thyroid
- (c) Hypofunction of the parathyroid
- (d) Hyperfunction of the parathyroid
- 69. Which of the following hormones does not contain a polypeptide [KCET 2009]
 - (a) Prostaglandin
- (b) Oxytocin
- (c) Insulin
- (d) Antidiuretic hormone
- 70. Damage to thymus in a child may lead to

[AIIMS 2007; KCET 2009]

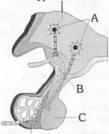

- (a) Loss of cell mediated immunity
- (b) A reduction in the haemoglobin content in blood
- (c) A reduction in the amount of plasma proteins
- (d) Loss of antibody mediated immunity
- 71. Which hormone causes dilation of blood vessels, increased oxygen consumption and glucogenesis [CBSE PMT 2006]
 - (a) Adrenalin
- (b) Glucagon
- (c) ACTH
- (d) Insulin

72. Consider the following figures. Identify A to D

[NCERT]

- (a) A Thyroid, B Corpus luteum, C Trachea, D -Parathyroid gland
- (b) A Thyroid, B Isthmus, C Larynx, D Parathyroid
- (c) A Thyroid, B Isthmus, C Trachea, D Parathyroid gland
- (d) A Parathyroid gland, B Isthmus, C Trachea, D -Thyroid
- 73. Which of the following hormone is not involved in tyrosine metabolism [CPMT 2010]
 - (a) Calcitonin
- (b) Melanin
- (c) Thyroxine
- (d) Epinephrine
- 74. See the given diagrammatic representation. Identify A, B, C and D [NCERT] Hypothalamus

- (a) A Hypothalamic neurons, B Portal circulation, C -Posterior pituitary, D - Anterior pituitary
- (b) A Hypothalamic neurons, B Portal circulation, C -Anterior pituitary, D - Posterior pituitary
- (c) A Epithalamic neurons, B Hypothalamic vein, C -Pars distalis, D - Pars intermedia
- (d) A Hypothalamic neurons, B Hypothalamic artery, C - Posterior pituitary, D - Anterior pituitary
- 75. An adenohypophysis hormone which is regulated by feedback mechanism is [Kerala PMT 2009]
 - (a) Oxytocin
- (b) TSH
- (c) Vasopressin
- (d) Cortisone
- (e) Calcitonin
- 76. Match the hormones with its source of secretion

(A)	Somatostatin	(1)	Pineal gland
(B)	Melatonin	(2)	Corpus luteum
(C)	Aldosterone	(3)	Placenta
(D)	Progesterone	(4)	Adrenal cortex
(E)	HCG	(5)	Islet of Langerhans
	With Laws	(6)	Adenohypophysis

[Kerala PMT 2009; CPMT 2010]

- (a) (A) (5), (B) (1), (C) (6), (D) (3), (E) (2)
- (b) (A) (1), (B) (2), (C) (4), (D) (3), (E) (5)
- (c) (A) (2), (B) (6), (C) (4), (D) (5), (E) (3)
- (d) (A) (5), (B) (1), (C) (4), (D) (2), (E) (3)
- (e) (A) (1), (B) (3), (C) (4), (D) (2), (E) (5)

- The source of somatostatin is same as that of [AIIMS 2003]
 - (a) Thyroxine and calcitonin
 - (b) Insulin and glucagon
 - (c) Somatotropin and prolactin
 - (d) Vasopresin and oxytocin
- 78. The chemical substances released by activated spermatozoa that acts on the ground substances of the follicle cells is known as [Kerala PMT 2009]
 - (a) Progesterone
- (b) Hyaluronidase
- (c) Relaxin
- (d) Gonadotropin
- (e) Teratogen
- 79. Match list I with list II and choose the correct answer

	List I	List II				
(A)	Hypothalamus	(1)	Sperm lysins			
(B)	Acrosome	(2)	Estrogen			
(C)	Graafian follicle	(3)	Relaxin			
(D)	Leydig cells	(4)	GnRH			
(E)	Parturition	(5)	Testosterone			

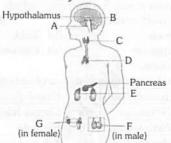

[Kerala PMT 2009]

- (a) (A) (4), (B) (1), (C) (2), (D) (3), (E) (5)
- (b) (A) (2), (B) (1), (C) (4), (D) (3), (E) (5)
- (c) (A) (2), (B) (1), (C) (5), (D) (4), (E) (3)
- (d) (A) (4), (B) (1), (C) (2), (D) (5), (E) (3)
- (e) (A) (5), (B) (1), (C) (3), (D) (2), (E) (4)
- 80. Which one of the following hormone never reaches to cytoplasm [BHU 2008]
 - (a) Estrogen
- (b) FSH
- (c) Progesterone
- (d) Testosterone
- 81. Find the odd one out

- [BHU 2008]
- (a) Parathyroid tetany
 - (b) Pancreas diabetes insipidus
 - (c) Adrenal cortex Cushing's syndrome
 - (d) Thyroid goitre
- 82. Which endocrine gland stores its secretion in the extracellular space before discharging it into the blood

[CBSE PMT 1995; Odisha JEE 2005]

- (a) Adrenal
- (b) Pancreas
- (c) Testis
- (d) Thyroid
- 83. Which of the following radioactive isotopes is used in the detection of thyroid cancer [CBSE PMT 1995]
 - (a) Iodine-131
- (b) Carbon-14
- (c) Uranium-238
- (d) Phosphorus-32
- 84. See the given figure which related with principal endocrine glands in human. Identify A to G [NCERT]

- (a) A Pituitary, B Pineal, C Thyroid and parathyroid, D - Thymus, E - Adrenal, F - Testis, G - Ovary
- (b) A Pituitary, B Pineal, C Thyroid and parathyroid, D - Thymus, E - Kidney, F - Testis, G - Ovary
- (c) A Pituitary, B Pineal, C Thyroid and parathyroid, D - Thymus, E - Adrenal, F - Ovary, G - Testis
- (d) A Pineal, B Pituitary, C Thyroid and parathyroid, D - Thymus, E - Adrenal, F - Testis, G - Ovary

- Adrenal gland is derived from
- [MP PMT 2007]

- (a) Ectoderm
- (b) Mesoderm
- (c) Ectoderm and mesoderm (d) Ectoderm and endoderm
- Which of the following is not an endocrine gland

[Odisha JEE 2010]

Or

Which of the following does not secrete any hormones

- (a) Liver/spleen
- (b) Pancreas
- (c) Testes
- (d) Thymus
- 87. Melanin is secreted by
- [MP PMT 2013]
- (a) Erythroblasts of blood
- (b) Chromatophores of skin
- (c) Cells of stratum compactum
- (d) Ganglia of sensory nerves
- Which of the following hormones has no effect on heart beat 88.
 - (a) Thyroxine
- (b) Oxytocin
- (c) Adrenaline
- (d) Noradrenaline
- Which of the following glands is associated with the 89. consumption of iodized salt

[RPMT 1995; CPMT 1999; JIPMER 2001]

Or

Thyroxine is secreted by

- [RPMT 1999]
- (a) Thyroid
- (b) Thymus
- (c) Pituitary
- (d) Ovary
- The hormone which regulates the basal metabolism in our body, is secreted from [CPMT 1998]
 - (a) Pituitary
- (b) Thyroid
- (c) Adrenal cortex
- (d) Pancreas
- 91 Hormones thyroxin, adrenaline and the pigment melanin are formed from [CBSE PMT 1997]
 - (a) Tryptophan
- (b) Glycine
- (c) Tyrosine
- (d) Proline
- lodine is associated with
- [CBSE PMT 1997; BHU 2001; WB JEE 2016]
- (a) Thyroxin
- (b) Calcitonin
- (c) Oxytocin
- (d) Secretin
- is a globular protein of ~6 kDa consisting of 93. 51 amino acids, arranged in 2 polypeptide chains held together by disulphide bridge [AMU (Med.) 2012]
 - (a) Insulin
- (b) Keratin
- (c) Glucagon
- (d) Fibrinogen
- Which of the following gland plays a key role in 94. metamorphosis of frog's tadpole [AIIMS 1999; CPMT 2003]
 - (a) Adrenal
- (b) Thymus
- (c) Pancreas Goitre affects
- (d) Thyroid

[MP PMT 2000]

(a) Metabolism

95.

- (b) Vision
- (c) Excretion
- (d) Speech
- Why thyroxine is a hormone not an enzyme [RPMT 2001]
 - (a) It is secreted in small quantity
 - (b) It is not a polypeptide
 - (c) It has no special effect
 - (d) It is directly poured into blood

The other name for autoimmune thyroiditis is [RPMT 1995; MP PMT 2001; BHU 2002; JIPMER 2002] An autoimmune disease where the body's own antibodies attack the cells of thyroid is **IMP PMT 20071** (a) Addison's disease (b) Simmond's disease (c) Hashimoto's disease (d) Cushing's disease Toxic agents present in food which interfere with thyroxine synthesis lead to the development of [CBSE PMT (Pre.) 2010] Or Disease related to thyroxin hormone [CPMT 2003] (a) Thyrotoxicosis (b) Toxic goitre (c) Cretinism (d) Simple goitre 'Royal jelly' is secreted from [WB JEE 2008] (a) Hypopharyngeal gland (b) Salivary gland (c) Milk gland Integumentary gland 100. Hypoparathyroidism results to (a) Upset in metabolism (b) Improper gonodial function (c) Convulsions and tetany (d) Nervousness and wasting 101. Parathormone induces [CPMT 1991, 92, 93: MP PMT 1996, 97, 2002; Pb. PMT 1999; RPMT 2000; BHU 2000; AMU (Med.) 2006] (a) Increase in serum calcium level (b) Decrease in serum potassium level (c) Increase in blood sugar level (d) Decrease in blood sugar level 102. If parathyroid gland of a child is removed, which activity is disturbed [CPMT 1993; AIIMS 2013] (a) Growth (b) Calcium concentration (c) Potassium concentration (d) None of these 103. Diabetes mellitus is caused due to [Odisha JEE 2012] (a) Underproduction of insulin (b) Underproduction of glycogen (c) Overproduction of insulin (d) Overproduction of glycogen 104. In case the islets of Langerhans stop functioning which hormone will be in short supply and what will be its effect [MP PMT 2006] (a) Insulin-Blood glucose level will rise (b) Adrenaline-Heart beat will increase (c) Thyroxin-Growth will be retarded (d) Cortine-Tetany will develop 105. Hypokalaemia means [MP PMT 2011] (a) High level of potassium in blood (b) High level of sodium in blood (c) Low level of potassium in blood (d) Low level of sodium in blood 106. Most of the contraceptive pills contain [CBSE PMT 1998, 99: BVP 2002; AFMC 2009; WB JEE 2012] (a) Estrogen + FSH (b) Progesterone + LH (c) FSH + LH (d) Oestrogen + progesterone except

107. Insulin increases glucose uptake in all the following

[CBSE PMT 2001]

(b) Skeletal muscle

(d) Intestinal mucosa

structures except

(a) Cardiac muscle

(c) Adipose tissue

108. Parathormone is secreted during [J & K CET 2002; RPMT 2005] (a) Increased blood calcium level (b) Decreased blood calcium level (c) Increased blood sugar level (d) Decreased blood sugar level 109. Which of the following pairs of hormones are not antagonistic (having opposite effects) to each other [NEET (Phase-I) 2016] (a) Parathormone Calcitonin (b) Insulin Glucagon (c) Aldosterone Atrial Natriuretic Factor (d) Relaxin Inhibin 110. Angiotensin derived from plasma protein "angiotensinogen" by the action of renin and other nervous stimuli. Angiotensin stimulates the following [CBSE PMT 1992] (a) Thyroid (b) Adrenal (c) Ovary (d) Thymus 111. The hormones that initiate ejection of milk, stimulates milk production and growth of ovarian follicles are respectively known as [Kerala PMT 2006] (a) PRL, OT and LH (b) OT, PRL and FSH (c) LH, PRL and FSH (d) PRH, OT and LH (e) PRH, OT and FSH 112. The mineralocorticoid hormone of the adrenal cortex which causes the Na retention and K excretion is CMC Vellore 1993; Kerala PMT 2010; WB JEE 2011] Conn's disease is caused by the over-secretion of [AIIMS 1999] (a) Corticosol (b) Corticosterone (c) Progesterone (d) Aldosterone 113. Which one of the following cells, found in testes of rabbit secretes male hormone [CBSE PMT 1998] (a) Leydig's cell (b) Sertoli cells (c) Epithelial cells (d) Spermatocytes 114. Which one of the following hormone controls the water and mineral metabolism (a) Progesterone (b) Insulin (d) Deoxycorticosterone (c) Succus entericus 115. If a human female starts developing male characteristics like beared, degeneration of uterus and ovaries, enlargement of clitoris etc. It may be due to (a) Over production oestrogen and testosterone (b) Damage to posterior pituitary (c) Over production of adrenal androgens (d) Surgical removal of mammary gland 116. Which is not a gonadal hormone [MP PMT 1993] (a) Progesterone (b) Testosterone (c) Adrenalin (d) Oestrogen 117. Goitre can occur as a consequence of all the following [WB JEE 2009]

(a) Iodine deficiency

(b) Pituitary adenoma

(d) Excessive intake of exogenous thyroxine

(c) Grave's disease

1200	Cushing's syndrome and myxoedema are associated with these glands respectively [CBSE PMT 1993]	 Hormone involved in the discharge of pancreatic juice in mammals is
	(a) Thyroid, adrenal (b) Adrenal, thyroid	(a) Secretin (b) Gastrin
	(c) Parathyroid, thyroid (d) Adrenal, pituitary	(c) Cholecytokinin (d) Enterogasterone
119.	Cholecystokinin and secretin are [CBSE PMT 1990; JIPMER 1993; MP PMT 1994, 95]	132. Hypothyroidism in adults and hyperparathyroidism will respectively lead to [Kerala PMT 2006]
	(a) Hormones liberated by mucosa of duodenum and	(a) Myxoderma and Cretinism
	stimulate gall bladder and pancreas respectively	(b) Grave's disease and Hashimoto's disease
	(b) Hormones stimulating liver	(c) Myxoedema and Osteitis fibrosa cystica
	(c) Hormones stimulating pancreas	
	(d) Enzymes	(d) Addison's disease and Cretinism
120.	Deficiency in the activity of adrenal cortex leads to	(e) Cretinism and Osteitis fibrosa cystica
	[MP PMT 2002, 06]	133. Which one of the following pairs is incorrectly matched
	(a) Addison's disease (b) Simmond's disease	[CBSE PMT (Pre.) 2010]
101	(c) Cohn's syndrome (d) Cushing's disease	(a) Insulin-Diabetes mellitus (Disease)
121.	Which of the following hormone governs the metabolism of	(b) Glucagon-Beta cells (Source)
	carbohydrates [CBSE PMT 1993]	(c) Somatostatin-Delta cells (Source)
	(a) Corticoids (b) Glucagon	(d) Corpusluteum-Relaxin (Secretion)
100	(c) Insulin (d) Glucagon and insulin	134. The main function of nor-adrenaline is [CPMT 1995]
122.	Which one of the following is both hormone and enzyme	(a) Contraction of arteries
	[RPMT 2000] (a) ADH hormone (b) Acetylcholinesterase	(b) To stop contraction of arteries
	(o) Theory and a second	(c) Relaxation
100	(c) Angiotensinogen (d) Renin	(d) None of the above
123.	Blood pressure is controlled by [NCERT; MP PMT 2004]	135. Cause of Addison's disease is
	(a) Adrenal (b) Thyroid	[CPMT 1996, 99; AIIMS 1998; MP PMT 2003]
104	(c) Thymus (d) Corpus luteum	(a) Hyposecretion of aldosterone hormone
124.	Which of the following endocrine glands functions under	(b) Hypersecretion of aldosterone hormone
	nervous control	(c) Hyposecretion of cortisone hormone
	(a) Cortex of adrenal glands (b) Medulla of adrenal glands	(d) Hypersecretion of cortisone hormone
105	(c) Anterior pituitary glands (d) Posterior pituitary gland	136. Life saving hormone is secreted by which gland
123.	Insulin is secreted by	[MP PMT 1999]
	[BVP 2001; Odisha PMT 2002; CPMT 2003] (a) Pituitary (b) Pancreas	(a) Adrenal gland (b) Hypothalamus gland
		(c) Pituitary gland (d) Thyroid gland
196	(=) 119.113	137. Which hormone can increase rate of formation of glycogen,
120.		volume of blood in vessel and rate of heart beat
		[KCET 1994; CPMT 1998]
197	1. T.	(a) Insulin (b) Glucagon
121.	Adrenal glands are found located in abdominal cavity in close association with	(c) Adrenalin (d) FSH
	[MP PMT 1994; AFMC 2003; Odisha JEE 2012] Or	138. Which of the following hormones is a derivative of amino acid [AIIMS 1999; MP PMT 2010; Kerala PMT 2010, 11]
	Which one of the following is not a gland [AFMC 2003]	(a) Oestrogen (b) Epinephrine
	(a) Testes (b) Spleen	(c) Progesterone (d) Prostaglandin
	(c) Liver (d) Kidneys	139. Glucagon hormone is secreted by [CBSE PMT 1993]
128.	The genetic deficiency of ADH-receptor leads to	(a) Pituitary
	[MP PMT 2001; WB JEE 2008, 09]	(b) Adrenal
	(a) Diabetes mellitus (b) Glycosuria	(c) Beta cells of islets of Langerhans
	(c) Diabetes insipidus (d) Nephrogenic diabetes	(d) Alpha cells of islets of Langerhans
	Which of the following is correctly matched [AFMC 2009, 10]	140. Nor epinephrine is secreted from [RPMT 2000]
	(a) Thyroxine - tetanus (b) Insulin - diabetes insipidus	(a) Zona glomerulosa (b) Zona fasciculata
	(c) Adrenaline – hepatitis (d) Parathyroid - tetany	(c) Zona reticularis (d) Medulla of adrenal
	Catecholamine in a normal person induces [AIIMS 2012]	141. Which gland is concerned with salt equilibrium in body
	(a) Intense salivation (b) Alertness	[RPMT 2001]
	(c) Decrease in heart beat (d) Excessive urination	(a) Anterior pituitary (b) Pancreas (c) Adrenal (d) Thyroid
	(a) Dicessive difficulti	(c) Adrenal (d) Thyroid

142. Which one affects liver, muscle and adipose tissue

[BHU 2003]

Or

Name a peptide hormone which acts mainly on hepatocytes, adipocytes and enhances cellular glucose uptake and utilization [NEET (Phase-II) 2016]

- (a) Androgen
- (b) Insulin
- (c) Progesterone
- (d) Glucagon
- 143. Hassal's bodies/corpuscles
- [DPMT 2006]
- (a) Adrenal medula (c) Thymus
- (b) Thyroid
- 144. Norepinephrine
- (d) Parathyroid
- [RPMT 2006; NEET (Karnataka) 2013]
 - (A) Is released by sympathetic fibers
 - (B) Is released by parasympathetic fibers
 - (C) Increases the heart rate
 - (D) Decreases blood pressure

Which of the above said statements are correct

- (a) (A) and (C)
- (b) (B) and (C)
- (c) (B) and (D)
- (d) (A) and (D)
- 145. Pineal body originates from

[MP PMT 2003]

- - (a) Dorsal part of diencephalon
 - (b) Ventral part of diencephalon
 - (c) Ventral part of cerebellum
 - (d) Dorsal part of cerebellum
- 146. According to recent knowledge, the pineal body is considered as
 - (a) A vestigeal organ
 - (b) An organ of intelligence
 - (c) An endocrine gland
 - (d) An organ of involuntary action
- 147. Identify the hormone with its correct matching of source and [CBSE PMT 2014]
 - (a) Progesterone corpus-luteum, stimulation of growth and activities of female secondary sex organs
 - (b) Atrial natriuretic factor ventricular wall increases the blood pressure
 - (c) Oxytocin posterior pituitary, growth and maintenance of mammary glands
 - (d) Melatonin pineal gland, regulates the normal rhythm of sleepwake cycle
- 148. Daily rythms are usually associated with

[CPMT 1999; JIPMER 2001]

One of the following endocrine gland functions as a biological clock and a neurosecretory transducer

[Kerala PMT 2006]

- (a) Pineal
- (b) Pituitary
- (c) Thymus
- (d) Hypothalamus
- 149. In a pregnant woman having prolonged labour pains, if child birth has to be hastened i.e to aid parturition, it is advisable to administer a hormone that can [DPMT 1993]
 - (a) Activate the smooth muscles
 - (b) Increase the metabolic rate
 - (c) Release glucose into the blood
 - (d) Stimulate the ovary

- 150. Which one of the following statement about sex hormones is [MP PMT 1992]
 - (a) Testosterone is produced by Leydig cells under the influence of luteinizing hormone (LH)
 - (b) Progesterone is secreted by corpus luteum and soften ligaments during child birth
 - Estrogen is secreted by both Sertoli cells and corpus luteum
 - (d) The progesterone produced by corpus luteum is biologically different from the one produced by placenta
- **151.** Luteinizing hormone

IKCET 19941

- (a) Stimulates ovulation
- (b) Stimulates the egg mother cell to undergo completion of
- (c) Stimulates the corpus luteum to secrete progesterone
- (d) All of the above
- 152. Testosterone, a hormone responsible for the development of secondary sexual characteristics in male is produced by the

[AIIMS 1992]

[MP PMT 2013]

- (a) Spermatogonia
- (b) Seminiferous tubules
- (c) Anterior lobe of the pituitary
- (d) Cells that lie between seminiferous tubules
- 153. Parathormone influences calcium absorption in the small intestine by regulating the metabolism of
 - [AMU (Med.) 2010; DUMET 2010]
 - (a) Vitamin C
- (b) Vitamin D
- (c) Vitamin B6
- (d) Enterogasterone
- 154. Continued secretion of milk is maintained by

[MP PMT 1993; CPMT 2001, 03; MH CET 2006]

Which of the following is a lactogenic hormone

(a) Prolactin (b) Progesterone

- (c) Estrogen (d) Relaxin
- 155. Signal from fully developed foetus and placenta ultimately lead to parturition(child birth) which requires the release of

[NCERT; DPMT 1993; CBSE PMT 1999; CPMT 2001; CBSE PMT (Mains) 2010; NEET (Karnataka) 2013]

- (a) Estrogen from placenta
- (b) Oxytocin from maternal pituitary
- (c) Oxytocin from foetal pituitary
- (d) Relaxin from placenta
- 156. Progesterone hormone is secreted by [NCERT; CPMT 2001; MP PMT 1994, 96, 2009; BHU 2003; CBSE PMT 2014]
 - (a) Corpus luteum
- (b) Corpus callosum
- (c) Corpus uteri
- (d) Corpus albicans
- 157. Diabetes is due to
- [CBSE PMT 1999] (b) Hormonal deficiency
- (a) Na+ deficiency (c) Enzyme deficiency
- (d) Iodine deficiency
- 158. Hormone responsible for the implantation of embryo in uterus and formation of placenta is [BHU 1999]

Pregnancy hormone is

[CPMT 1994]

(a) Adrenalin

(b) Progesterone

(c) Estradiol

(d) FSH

		Stomach		Spleen		(d)	Ovary	Insulin		Calcitonisn	

178. Which hormone stimulates the secretion of milk during sucking of milk by baby [CBSE PMT 1996]

Or

Which hormone is responsible for milk ejection after the birth of the baby [MP PMT 2007; WB JEE 2010]

- (a) Oxytocin
- (b) Relaxin
- (c) Prolactin
- (d) Progesteron
- 179. Which hormone among these is not secreted by an endocrine gland [Kerala PMT 2012]
 - (a) ADH
- (b) ANF
- (c) T₄
- (d) PTH
- (e) MSH
- 180. Choose the mismatched pair from the following [KCET 2012]
 - (a) Insulin Gluconeogenesis
 - (b) Glucagon Glycogenolysis
 - (c) Oxytocin Contraction of uterine muscles
 - (d) Prolactin Milk production in mammary glands -
- 181. Match the source gland with its respectively hormone as well as the function[NCERT; CBSE PMT (Pre.) 2011; NEET 2013]

	Source gland	Hormone	Function
(a)	Thyroid	Thyroxine	Regulates blood calcium level
(b)	Anterior pituitary	Oxytocin	Contraction of uterus muscles during child birth
(c)	Posterior pituitary	Vasopressin	Stimulates reabsorption of water in the distal tubules in the nephron
(d)	Corpus luteum	Estrogen	Supports pregnancy

182. Match the column I with column II and select the correct

(Column I	with b	Column II
A.	ANF	1.	Regulates blood calcium levels
B.	MSH	2.	Decreases blood pressure
C.	GIP	3.	Pigmentation
D.	TCT	4.	Inhibits gastric secretion

[Kerala PMT 2011; MH CET 2015]

- (a) A-4, B-1, C-2, D-3
- (b) A-2, B-1, C-4, D-3
- (c) A-4, B-1, C-3, D-2
- (d) A-3, B-2, C-4, D-1
- (e) A-2, B-3, C-4, D-1
- 183. During menstruation the level of progesterone in blood is [DPMT 2003]
 - (a) Low
- (b) High
- (c) Normal
- (d) Very high
- 184. Hormone prolactin was discovered by
 - (a) Riddle
- (b) Hisaw
- (c) Leonard
- (d) Hisaw and Leonard
- 185. During pregnancy which of the following is secreted through urine of mother [NCERT; CPMT 1993;

AIEEE Pharmacy 2003; MP PMT 2009, 11; WB JEE 2012]

Or

The persistance of corpus luteum during pregnancy is due to a hormone known as [MP PMT 2001]

- (a) Progestron
- (b) Luteinizing hormone
- (d) Chorionic gonadotropin

186. When mammary glands of male develop similar to that of female, then this condition is known as

[Odisha JEE 2005; J & K CET 2010]

- (a) Gonochorism
- (b) Gynaecomastia
- (c) Feminism
- (d) Gynaecism
- 187. Select the correct matched pair [Kerala PMT 2011]

(a)	Pineal gland	-	Does not influence menstrual cycle
(b)	Corpus luteum	-	Secretes oxytocin
(c)	Interstitial cells	-	Erythropoietic
(d)	Cholecystokinin	-	Stimulates pancreatic enzyme secretions
(e)	Thyroxine	-	Triiodothyronine

188. Diabetes mellitus is caused due to the deficiency of insulin which is secreted by [MP PMT 1992, 95, 98, 2001:

CPMT 1996; RPMT 2001; Odisha JEE 2012]

- (a) Alpha cells
- (b) Beta cells
- (c) Pituitary
- (d) Thyroid
- 189. Which of the following statements are false/true
 - A. Calcitonin regulates the metabolism of calcium
 - B. Oxytocin stimulates contraction of uterine muscles during birth
 - Grave's disease is caused by malfunctioning of adrenal gland
 - D. ADH stimulates absorption of water and increase the urine productions [Kerala PMT 2007]
 - (a) A and C are true; B and D are false
 - (b) A and B are true; C and D are false
 - (c) A and D are false; B and C are true
 - (d) A, B and C are true; D only false
 - (e) A only true; B, C and D are false
- 190. Match the columns

Column-I

Column-II

- Adrenaline A
- Anger, fear, danger, pain
- B. Oestrogen
- Attracting partners through sense of smell
- C. Insulin
- 3. Females
- D Pheromones
- Glucose

- [Kerala CET 2003; AIIMS 2010]
- A B C D (a) 3 1 4 2
- (b) 1 3 2 4
- (c) 1 3 4 2
- (d) 3 1 2 4
- 191. The function of glucagon hormone is

[MP PMT 2003]

- (a) To increase glycogenesis
- (b) To decrease blood sugar level
- (c) To release glucose from liver cells and glycogenolysis promotion
- (d) To increase the absorption of glucose and fatty acids through cell
- 192. Glucagon and insulin are

[Bihar MDAT 1995; AIEEE Pharmacy 2003]

- (a) Antagonistic secretions
- (b) Secreted by same cells and perform similar function
- (c) Secreted by different cells and perform antagonistic function
- (d) Secreted by same cells and perform antagonistic functions
- (e) None of the above

193. Which one of the following hormone is antiinflamatory

[MP PMT 1992]

- (a) Secretin
- (b) Epinephrin
- (c) Glucoprotein
- (d) Glucocorticoid
- 194. An overdose of intravenous insulin may lead to the death of an individual due to [MP PMT 1992]
 - (a) An excessive increase of blood glucose
 - (b) An excessive decrease of blood glucose
 - (c) An inhibition of glucagon secretion
 - (d) An over production of histamine
- 195. Pancreas secretes

[RPMT 1995]

- (a) Digestive enzymes
- (b) Insulin
- (c) Glucagon
- (d) All the above
- 196. Gluconeogenesis is controlled by (a) Cortisol
- [CPMT 1994]
- (b) Corticosterone
- (c) Thyroxine
- (d) All the above
- 197. 'Mammalian thymus' is mainly concerned with [BHU 2006]
 - (a) Regulation of body temperature
 - (b) Regulation of body growth
 - (c) Immunological functions
 - (d) Secretion of thyrotropin
- 198. The structure of insulin consists of two polypeptide chains A and B. These two polypeptide chains
 - (a) Have equal number of amino acids
 - (b) Chain A has 21 amino acids, while chain B has 30 amino acids
 - (c) Chain A has 30 amino acids, while chain B has 21 amino acids
 - (d) Chain A has 11 amino acids, while chain B has 40 amino acids
- 199. Match column I (hormone) with column II (endocrine gland) and column III (function)

	Column I		Column II		Column III
1.	Melatonin	A.	Thyroid	i.	Acts on the renal tubules
2.	MSH	B.	Adrenal	ii.	Regulates blood calcium levels
3.	Aldosterone	C.	Pituitary	iii.	Maintains diurnal rhythm of our body
4.	TCT	D.	Pineal	iv.	Acts on the melanocytes

[Kerala PMT 2012]

- (a) 4-A-iv; 3-D-iii; 1-B-ii;; 2-C-i
- (b) 1-D-iii; 2-C-iv; 3-B-i; 4-A-ii
- (c) 1-B-i; 4-A-iii; 3-C-ii; 2-D-iv
- (d) 2-D-ii; 1-B-I; 4-C-iv; 3-C-iii
- (e) 2-C-iv; 3-A-ii; 1-D-iii; 4-B-i
- 200. Which of the following hormones is responsible for hoarseness in voice, beard, moustaches etc. in males

[CPMT 1995]

- (a) Gonadotropic hormone (b) Adrenaline
- (c) Thyroid
- (d) All the above
- 201. Which hormone(s) of the following endocrine glands lacks peptides, amines and sulphur [AFMC 1995]
 - (a) Hormone of anterior pituitary
 - (b) Hormone of posterior pituitary and pancreas
 - (c) Hormone of thyroid and adrenal gland
 - (d) Hormone of testes and ovary

- 202. With reference to the pituitary, which of the following [KCET 2011] statements is true
 - (a) Neurohypophysis secretes vasopressin and oxytocin
 - (b) Neurohypophysis secretes TSH and STH
 - (c) Neurohypophysis collects and stores vasopressin and oxytocin
 - (d) Adenohypophysis secretes vasopressin and oxytocin
- 203. Progesterone is a

(c) Protein

- [RPMT 1995]
- (a) Carbohydrate
- (b) Steroid (d) Sterol
- 204. Low Ca++ in the body fluid may be the cause of
 - [CBSE PMT (Pre.) 2010]

- (a) Gout
- (b) Tetany
- (c) Anaemia
- (d) Angina pectoris
- 205. Gorilla like man with large head and hands and protruding jaws, is produced due to [MP PMT 1997]
 - (a) Over secretion of thyroxin
 - (b) Over secretion of growth hormone since maturity
 - (c) Excess of vitamin 'C' in diet
 - (d) Excess secretion of TSH
- 206. In males, the essential hormone for secondary sexual characteristics is [MP PMT 1999]

Or

The hormone which brings about characteristic changes in the male at puberty is called

- (a) Testosterone
- (b) Progesterone
- (c) Estrogen
- (d) Relaxin
- 207. The adrenal cortex synthesizes only (a) Steroid hormones
 - (b) Peptide hormones

[WB JEE 2016]

- (c) Glycopeptide hormones (d) Catecholamines
- 208. The posterior pituitary gland is not a 'true' endocrine gland because [NEET (Phase-II) 2016]
 - (a) It secretes enzymes
 - (b) It is provided with a duct
 - (c) It only stores and releases hormones
 - (d) It is under the regulation of hypothalamus
- 209. GnRH, a hypothalamic hormone, needed in reproduction,
 - (a) Anterior pituitary gland and stimulates secretion of LH and oxytocin
 - (b) Anterior pituitary gland and stimulates secretion of LH and FSH
 - (c) Posterior pituitary gland and stimulates secretion of oxytocin and FSH
 - (d) Posterior pituitary gland and stimulates secretion of LH and relaxin

- Select the right match of endocrine gland and their hormones among the options given below
 - A. Pineal
- Epinephrine
- B. Thyroid
- Melatonin ii.
- C. Ovary
- iii. Estrogen
- D. Adrenal medulla Options
- iv. Tetraiodothyronine
- (a) A-iv, B-ii, C-iii, D-i (c) A-iv, B-ii, C-i, D-iii
- (b) A-ii, B-iv, C-i, D-iii (d) A-ii, B-iv, C-iii, D-i

(c) Salivation of mouth at the sight of delicious food

vessels when it is too hot

(d) Secretion of sweat glands and constriction of skin blood

UNIVERSAL BOOK DEPOT 1960

Listed below are the hormones of anterior pituitary origin. Tick the wrong entry **INCERTI** Critical Thinking (a) Growth hormone (b) Follicle stimulating hormone Objective Questions (c) Oxytocin (d) Adrenocorticotrophic hormone In an accident the anterior pituitary of a four year old boy 3. Mary is about to face an interview. But during the first five was severely damaged but the boy survived. What is likely minutes before the interview she experiences sweating, [MP PMT 1992] increased rate of heart beat, respiration etc. Which hormone (a) High levels of thyroxin will be released is responsible for her restlessness (b) Spermatogenesis will be stimulated (a) Estrogen and progesterone (c) The boy will not grow much in height (b) Oxytocin and vasopressin (d) The growth of mammary glands will be stimulated (c) Adrenaline and noradrenaline Which one of the following hormones inhibits gastric (d) Insulin and glucagons secretion [CPMT 1992, 93] 4. The steroid responsible for balance of water and electrolytes (a) Gastrin (b) Secretin in our body is **INCERTI** (c) Enterogastrone (d) Cholecystokinin (a) Insulin (b) Melatonin 3. Feeling the tremors of an earthquake a scared resident of (c) Testosterone (d) Aldosterone seventh floor of a multistoryed building starts climbing down 5. Thymosin is responsible for [NCERT] the stairs rapidly. Which hormone initiated this action (a) Raising the blood sugar level [CBSE PMT 2007] (b) Raising the blood calcium level Or Increased production of T lymphocytes Injury to adrenal cortex is not likely to affect the secretion of (d) Decrease in blood RBC which one of the following [CBSE PMT (Pre.) 2010] One of the following conditions is not linked to deficiency of (a) Thyroxin (b) Adrenaline thyroid hormones [NCERT] (c) Glucagon (d) Gastrin (a) Cretinism (b) Goitre The correct set of a single endocrine gland hormone is (c) Myxoedema (d) Exophthalmosis Oxytocin, prolactin, ACTH Cortisol is secreted from [NCERT] (b) Oxytocin, vasopressin, ADH (a) Pancrease (b) Thyroid (c) Thyroxin, secretin, ACTH (c) Adrenal (d) Thymus (d) Epinephrin, cortisol, ICSH 8. Hormones are called chemical signals that stimulate specific Which of the following is an emergency hormone target tissues. Their specificity is due to the presence of [NCERT; CPMT 1995, 2000; AIIMS 2000; AFMC 2001; signal receiving 'receptors' only in the respective target MH CET 2003; BHU 2006; MP PMT 2013] tissues. Where are these receptors present in case of Or hormones of protein nature [NCERT] When an animal is angry and wants to fight, the hormone (a) Extra cellular matrix (b) Blood that is secreted is Plasma membrane (d) Nucleus (a) Pituitary (b) Prolactin 9. Choose the correct answer among the following options (c) Progesterone (d) Adrenalin A. Epinephrine i. Increase muscle Appearance of facial hairs in a woman may be due to the growth effect of [MP PMT 1992] Testosterone ii. Decrease in blood (a) Temperature (b) Ultraviolet radiation pressure (c) Hormone (d) Pollution Glucagon iii. Decrease liver 7. Thyroxine is [MP PMT 1998; BVP 2000] glycogen content (a) An enzyme (b) A hormone D. Atrial natriuretic factor iv. Increase heart beat (c) A vitamin (d) An excretory product Options: [NCERT] 8. If thyroid gland is completely removed from a tadpole, it will (a) A-ii, B-i, C-iii, D-iv (b) A-iv, B-i, C-iii, D-ii [MP PMT 2001] (c) A-i, B-ii, C-iii, D-iv (d) A-i, B-iv, C-ii, D-iii (a) Die immediately Blood calcium level is a resultant of how much dietary (b) Turn into a giant frog calcium is absorbed, how much calcium is lost in the urine, (c) Turn into a dwarf frog how much bone dissolves releasing calcium into the blood (d) Remain tadpole throughout its life and how much calcium from blood enters tissues. A number 9. Which one of the following is an example of negative of factors play an important role in these processes. Mark feedback loop in humans [CBSE PMT 2007] the one which has no role (a) Constriction of skin blood vessels and contraction of (a) Vitamin D (b) Parathyroid hormone skeletal muscles when it is too cold (c) Thyrocalcitonin (d) Thymosin (b) Secretion of tears after falling of sand particles into the 11. All the following tissues in mammals except one consists of a central 'medullary' region surrounded by a cortical region.

INCERTI

(b) Adrenal

(d) Kidney

Mark the wrong entry

(a) Ovary

(c) Liver

In the homeostatic control of blood sugar level, which organs function respectively as modulator and effector [KCET 2006] (a) Liver and islets of langerhans (b) Hypothalamus and liver (c) Hypothalamus and islets of langerhans (d) Islets of langerhans and hypothalamus The urine of a man is very dilute and the quantity of urine is too much and dehydration has started in his body and he is very thirsty by the cause of [CPMT 1994] (a) Hypersecretion of ADH (b) Hyposecretion of ADH (c) Both (a) and (b) (d) None of the above Which of the following pair of hormones is responsible for 12. the growth and maturation of the graafian follicle [MP PMT 1995; BHU 2006] (a) GH-ADH (b) ACTH-LH (c) FSH-LH (d) FSH-LTH FSH and LH hormones together are called 13. [MP PMT 1997, 2002; CPMT 2000; HPMT 2005] (a) Emergency hormones (b) Gonadotropic hormones (c) Neurohormones (d) Outstress hormones Secretion of progesterone by corpus luteum is initiated by [CBSE PMT 1999] (a) MSH (b) LH (c) Testosterone (d) Thyroxine Which hormone promotes cell division, protein synthesis and bone growth [AFMC 1999; BVP 2000; RPMT 2002] (a) GH (STH) (b) PTH (c) ADH (d) ACTH 16. Function of hypothalamus is [RPMT 1995] (a) Helps in sleeping (b) Related to hunger and thirst (c) Temperature regulation (d) All the above Which of the following is both (mixed) exo and endocrine [AFMC 2000; RPMT 2001; MP PMT 2002; Odisha JEE 2012] (a) Thyroid (b) Pancreas (c) Payer's patches (d) Thymus Which endocrine gland becomes inactive in old age [MP PMT 1999; DPMT 2006] (a) Adrenal (b) Pineal (c) Thymus (d) Pituitary Which of the following is an accumulation and release centre of neurohormones [CBSE PMT 2006] (a) Hypothalamus (b) Anterior pituitary lobe (c) Posterior pituitary lobe (d) Intermediate lobe of the pituitary 20. Which of the following is not secreted by pituitary gland [RPMT 1995] (a) ACTH (b) GH (c) FSH (d) Thyroxine A man has an I.Q. equivalent to that of a boy 5 years old, this is due to deficiency of which hormone (a) Thyroxin (b) Adrenaline (c) Aldosterone (d) Somatotropin 22. Hypersecretion of Growth Hormone in adults does not cause further increase in height, because [NEET 2017] (a) Growth Hormone becomes inactive in adults

(b) Epiphyseal plates close after adolescence

(d) Muscle fibres do not grow in size after birth

(c) Bones loose their sensitivity of Growth Hormone in

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- If both the assertion and reason are true but the reason is (b) not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- 1. Assertion Diabetes insipidus is marked by excessive urination and too much thirst of water.
 - Reason Anti-diuretic hormone (ADH) is secreted by the posterior lobe of pituitary.

[AIIMS 2008]

- 2. Assertion Adrenal cortex can be removed without causing death.
 - Reason Adrenal cortex is not vital for survival.
- Adrenal cortex is called the gland for 'fight, Assertion fright and flight'.
 - Reason The hormones adrenaline and noradrenaline help the body to combat against stress and emergency conditions.
- 4. Assertion FSH is also known as interstitial cell stimulating hormone.
 - It is because of the fact that FSH stimulates Reason the interstitial cells of testis.
- 5. Failure of secretion of somatotropin from Assertion an early age causes dwarfism in the patient.
 - Somatotropin hormone stimulates the body Reason growth and elongation of long bones.
- 6. Assertion A tumor of adrenal cortex may cause addison's disease.
 - Reason This happens due to over secretion of cortisol by the tumor.
- 7. Assertion Oxytocin is also known as Anti Diuretic hormone (ADH).
- Reason Oxytocin can cause an increase in the renal reabsorption of water.
- 8. Assertion Prolactin is also called the 'Milk ejection hormone'.
 - Reason Prolactin stimulates the smooth muscle contractions of the mammary glands.
- The tadpoles become giant tadpoles when Assertion fed on thiourea.
 - Thiourea is an antithyroid substance. Reason
- 10. Assertion Females have less stature than males after
 - Reason This happens because of the presence of HCG in the blood of females.

Answers and Solutions

Hormones and their mechanism

- (b) Cyclic AMP and GMP act as intracellular mediators and affect the cell metabolism in various ways. According to the second messenger theory given by Sutherland the 1st messenger is hormone itself and the 2nd messenger is cyclic AMP.
- (c) Hormone is a chemical messenger produced by 3. endocrine glands and secreted directly into the blood stream to exert a specific effect on a distant part of the
- 7. (a) Kupffer's cells occur in the lining of liver sinusoids and help in phagocytosis.
- (d) Hormone do not belong to a single chemical group but 9. are varied in their composition is polypeptide, proteins, amines or steroid.

- (b) Pheromones serve to conduct messages by smell and taste and affect the mutual behaviour of members of a species.
- 13. (d) The father of endocrinology is Thomas Addison. The first endocrine disease reported was Addison's disease caused by destruction of adrenal cortex.
- (c) Starling (1905) first used the term hormone for internal secretion.
- 15. (b) The molecules of amino acid derivatives, peptides or polypeptide (protein) hormones bind to specific receptor molecules located on the plasma membrane of target cells.
- 17. (c) Ionositoltriphosphate (IP₃) & diacylglycerol (DAG) act as intracellular secondary messengers responsible for amplification of signal. IP₃, being water soluble, diffuses in the cytoplasm to stimulate the release of Ca⁺² from endoplasmic reticulum of target cells. The latter activate many Ca⁺² mediated reactions. DAG remains in the cell membrane to activate the enzyme protein kinase C. Certain body cells use more than one secondary messenger, e.g. in heart cells, c-AMP acts as a secondary messenger to stimulate the release of Ca²⁺ from sarcoplasmic reticulum of muscle fibre resulting in muscle contraction.
 - Phospholipase is any of various enzymes that cleave particular bonds in the polar phosphate 'heads' of glyerophospholipids.
- (d) Hormones composition can be polypeptide proteins, amines or steroid.
- 20. (a) Endocrine glands are ductless gland their secretion flows directly into the blood stream.

Different glands and their hormones

- (d) Deficiency of somatotrophic hormone (STH) from early age result in growth of long bones and of the body stops prematurely making the patient Dwarf.
- 5. (c) Myxoedema occurs due to deficiency of thyroxine is adults. It is characterized by low BMR, low body temperature, reduced heart rate, pulse rate, cardiac output. Face and hands become swollen.
- (a) Aldosterone is secreted by adrenal cortex and is responsible for regulation of Na⁺ and K⁺ levels in body.
- (a) Both are neurohypophyseal hormones and ADH is the only other name for vasopressin.
- (d) In the male, ICSH stimulates the interstitial cells of leydig in testis to develop and secrete large amount of testosterone.
- (a) In male, FSH stimulates the testis to initiate sperm production.
- **16.** (c) Failure of secretion of vasopressin leads to a reduced renal reabsorption of water and a consequent elimination of a large volume of very dilute urine this disorder is known as diabetes incipidus.
- (d) ADH and oxytocin are secreted by hypothalamus and stored in posterior pituitary.
- 19. (c) Hypoparathyroidism results in hypocalcemia. Skeletal muscles fail to relax causing tetany and hyperparathyroidism result in osteoporosis i.e. dissolution of bone and hypercalcemia.

- (d) Cortisol and testosterone are steroid group of hormones which bind to intracellular receptor.
- 22. (c) MSH increases skin pigmentation by stimulating the dispersion of melanin granules in melanocytes. Since it affects the target cells directly i.e. it affect the distribution of melanin granules in the chromatophores/melanocytes directly.
- **25.** (b) Vasopressin decreases loss of water through urine. Glucagon is released from α cells. Prolactin is released from anterior pituitary.
- (c) Endemic goitre is due to low iodine in soil and water in hilly areas.
- 29. (d) The hyposecretion of GH in the adult life lead to a rare condition called "simmond's disease" The patient becomes quite thin and shows signs of premature ageing.
- 34. (a) At the dorsal surface of diencephalon.
- (b) Follicular stimulating hormone (FSH) is glycoprotein in nature.
- **38.** (c) The gonadotrophic hormones (FSH and ICSH (= LH) are secreted by anterior lobe of the pituitary (adenohypophysis).
- (b) Hypothalamus regulates body temperature.
- 43. (a) In pregnant female, hCG maintains the corpus luteum which secretes estrogen and progesterone.
- **45.** (a) Basophil cells of *pars distalis* or anterior pituitary secrete luteinizing hormone which is responsible for maintenance of corpus luteum.
- 46. (a) Pitressin is also called as ADH or vasopressin.
- 54. (a) In fight or flight reactions, emergency hormones are secreted by adrenal medulla.
- **56.** (a) Hypothalamus cells are also known to synthesize two more hormones: oxytocin and vasopressin which are stored in their axons extending in the posterior lobe of pituitary gland.
- 57. (b) Vasopressin reduces the excretion of water in urine by promoting its reabsorption from DCT. When vasopressin is released in lesser amounts, diuresis increases.
- 60. (d) Neurosecretory cells of hypothalamus secrete neurohormones called thyrotrophic releasing factors (TRF) or inhibiting factor (IF).
- **62.** (d) Calcitonin is a noniodinized hormone secreted by the parafollicular cells (clear or cells) of thyroid stroma.
- 64. (a) Simple goitre is caused by lower intake of iodine through diet, goitre is the swelling of neck due to enlargement of thyroid.
- 65. (c) Myxoedema occurs due to deficiency of thyroxine in adult. The peculiar feature of myxoedema is that face and hand become swollen due to deposition of albuminous myxomatous tissue.
- 66. (d) Acromegaly characterised by abnormal elongation of limbs and lower jaw, giving gorilla like appearance and kyphosis protruding bony ridge over the eyes. It occurs due to oversecretion of STH in adult.
- 67. (d) Hyposecretion of thyroxine during the growing years of birth is called childhood hypothyroidism or cretinism. Two important symptoms are dwarfism and mental retardation also.

- 68. (b) Exophthalmic goitre (Grave's disease) is hyperthyroidism. Eye balls protrude due to accumulation of mucus in eye orbits metabolic rate is abnormally high.
- 82. (d) Thyroid gland is made up of tiny follicles (hollow spheres whose wall is singly layered cuboidal epithelium). In these follicles, thyroid hormones are stored, and bound to a protein called thyroglobulin formed by the follicle. To release the hormones into the blood, the epithelial cells take up thyroglobulin by pinocytosis and remove the active hormone from thyroglobulin.
- 83. (a) lodine is used by thyroid gland for the synthesis of thyroid hormone. Thus radio active isotope iodine – 131 is used as radioactive material for detection of thyroid cancer.
- 89. (a) Iodine is essential for the synthesis of thyroid hormones. An adult human body contains about 5 to 6mg of iodine and most of it is found in thyroid gland. Thyroxine is iodine containing amine hormone which is derived from tyrosine amino acid and secreted by thyroid gland.
- 90. (b) The most important function of thyroid hormone is to enhance the basal metabolic rate in our body. They are secreted by thyroid gland.
- 94. (d) Thyroid initiate, regulates and plays a key role in the metamorphosis of frog's tadpole. The changes that takes place during transformation of larva into adult are called as metamorphosis.
- 101. (a) Parathormone is secreted by parathyroid gland. It is also called as parathymin. it controls calcium levels in blood plasma and metabolism.
- 106. (d) Contraceptive pills for women contain female sex hormones oestrogen and progesterone. These prevent development of eggs and ovulation by inhibiting secretion of FSH some pills contain progesterone only in such cases ovulation may occur but cervical mucus is thickened preventing the entry of sperm.
- 112. (d) Mineralocorticoids hormones are 21-carbon steroids secreted by the cells of zona glomerulosa of adrenal cortex. The principal mineralcorticoid is aldosterone. It is a salt retaining hormone". It upgrades sodium ion concentration in the ECF by promoting reabsorption of sodium ions from renal tubules and excretion of potassium ions in urine. Conn's disease is characterised by rise in blood volume and pressure and is caused due to over secretion of aldosterone.
- 113. (a) The endocrine part of testes is formed of groups of cells, called interstitial cell or leydig's cells. Leydig's cells of testes are stimulated to secrete male sex hormones called, androgen.
- 116. (c) Progesterone, Testosterone and Oestrogen these are the hormones of gonads. But the adrenalin is the hormone of adrenal medulla.
- **120.** (a) Hyposecretion of glucocorticoids which are a hormone of adrenal cortex results in addison's disease.
- 124. (b) Because adrenal medulla is a modified sympathetic ganglion of autonomic nervous system. It develops from same embryonic tissue as all other sympathetic ganglia develop.
- **127.** (d) Adrenal glands are paired endocrine glands located superior to kidney, hence called 'suprarenals'.

- 133. (b) Glucagon is secreted by α -cells of pancreatic islets.
- 136. (a) Life-saving hormones are secreted by adrenals. An increased output of cortisol is actually "life saving in shock condition".
- **137.** (c) Adrenalin increases the rate of heart beat and cardiac out put, so increases blood pressure.
- 138. (b) Epinephrine hormones are amine hormones and are derivatives of catechol, so collectively called catecholamines.
- 139. (d) Glucagon is a hyperglycaemic or diabetogenic polypetide hormone secreted by α-cells of islets of langerhans. Its secretion is stimulated by low blood sugar level.
- **140.** (d) Medulla of adrenal secrets nor-epinephrin/adrenalin hormone which is sympathomimetic.
- 141. (c) Aldosterone hormone of the adrenal cortex is also called salt retaining hormone. Increased sodium concentration increases salt concentration of interstitial fluid which increases water reabsorption.
- **143.** (c) Hassal's corpuscles are spherical or oval bodies present in the thymus. They are phagocytic in function.
- **145.** (a) Pineal gland is an endocrine organ, it is located on the roof of diencephalon.
- **146.** (c) Pineal body was considered vestigeal of 3rd eye earlier but now has been confirmed to be endocrine gland.
- **147.** (d) Pineal gland secretes three hormones namely melatonin, serotonin and adrenoglomerulotropin.
- 149. (a) The hormone oxytocin is sometimes used to hasten the child birth. It contracts the involuntary smooth muscles of the uterus to expel the child.
- 152. (d) Called Sertoli cells.
- 154. (a) Sucking at nipple causes reflexes to release oxytocin hormone from the posterior pituitary gland which in turn causes the contraction of breast alveoli and secretion of milk.
 - Prolactin another hormone is responsible for production of milk not its secretion.
- 155. (b) Oxytocin causes contraction of the smooth muscles of myometrium forcing the foetus out of the uterus. Oxytocin is also involved in ejection of milk, but not lactation (actual production of milk) for milk to be produced, prolactin must be present.
- 156. (a) Progesterone is a principal female sex hormones. It is a steroid. It is secreted during the later half of the menstrual cycle in human female by temporary endocrine tissue, the corpus luteum. The luteinizing hormone (LH) of anterior pituitary brings about a rupture of the graafian follicle to release the ovum, and changes the ruptured follicle into a yellow structure called corpus luteum, which secrets progesterone.
- 158. (b) Progesterone a hormone produced by mammalian corpus luteum maintains pregnancy. It is responsible for the implantation of embryo and formation of uterine bed and placenta, as well as for inhibiting of ovulation and action of oxytocin on uterus during pregnancy.
- 160. (a) The molecules of hormones that are amino acid derivatives, peptides or proteins are large and insoluble in lipids, and cannot enter the target cell. Therefore, they act at the cell surface. They bind to specific receptor molecules located on the surface of the cell membrane. Insulin is a polypeptide hormone, so it operates through extracellular membrane bound receptor, a heterotetrameric protein (extrinsic protein) on the target cell.

- 161. (b) Melatonin, secreted by the pineal gland, stimulates the concentration of pigment granules in the melanocytes, lightening the skin colour.
- **162.** (c) A temporary structure with endocrine function is placenta.
- **164.** (c) It increases width of vaginal passage by relaxing pelvic ligaments there by helps in parturition *i.e.* child birth.
- 166. (c) It increases synthesis and secretion of milk.
- **167.** (a) Pancreas is a hetrocrine gland. The endocrine part is formed of about 1 to 2 million groups of epithelial cells, called islets of langerhans.
- 171. (a) High sugar level in blood is called hyperglycemia.
- **175.** (a) Relaxin is a proteinous hormone secreted by the corpus albicans formed from the corpus luteum at the end of gestation period. It softens the public symphysis so help in parturition (child birth).
- 176. (c) Banting and Best (1921) extracted insulin from pancreas and showed that it reduces blood sugar in dogs.
- 177. (b) A. Ovary secretes oestrogen for maintenance of secondary sexual characters.
 - Alpha cells of Islets of Langerhans secrete glucagon which raises blood sugar level.
 - C. Anterior lobe of pituitary secretes growth hormone.
 Its over secretion leads to gigantism.
- 181. (c) Vasopressin (ADH) is synthesised in hypothalamus but released into the blood from posterior lobe of pituitary, so it is called as a hormone of posterior lobe. It stimulates reabsorption of water in distal tubules in the nephron.
- 185. (d) Its presence in urine confirms pregnancy, therefore used for pregnancy test.
- 186. (b) Excessive secretion of female hormones in adult males may cause enlarged mammary gland (Gynaecomastia) and retards growth of breast.
- 188. (b) Beta cells of islets of Langerhans.
- 192. (c) Glucagon is antagonistic to insulin. Antagonistic hormones are those which work against each others. Glucagon increases sugar level in blood and insulin decreases glucose level in blood.
- 193. (d) Glucocorticoids include three main hormones: cortisol, corticosterone and cortisone. Cortisone has anti insulin effect. It also helps in reducing pain cortisol is anti-in flammatory.
- **194.** (b) Oral dose of insulin is degenerated by the hydrolysing action of enzymes in the stomach.
- **195.** (d) Pancreas is a heterocrine gland which secrets both enzyme and hormone.
- 197. (c) 'Mammalian thymus' is a bilobed lymphoid organ situated in front of the heart in the upper part of sternum.
- 198. (b) Chemically insulin is a protein (large polypeptide)
 Insulin contains 51 amino acid arranged in two chain,
 an acidic A chain containing 21 amino acid residues
 and a basic B-chain containing 30 residue.

- 201. (d) Hormones produced by gonads i.e. testis and ovary are steroid in chemical nature i.e. they are derived from fats.
- **203.** (b) Chemical nature of progesterone is steroid (cholesterol) *i.e.* derived from fats.
- **205.** (b) The hypersecretion during adulthood is called acromegaly (after the closure of the epiphyseal plates at the ends of the bones) Acromegaly patient has a gorillalike appearance with huge hand and legs.
- 206. (a) Testosterone stimulates the development of male secondary sexual charcters like-beard, moustaches, deepening of voice, broadening of shoulders, increased height due to elongation of bones and increased development of limbs.
- 207. (a) All hormones of adrenal cortex are steroid in nature and are derived from cholesterol.

Critical Thinking Questions

- (c) Enterogasterone is secreted by the epithelium which inhibits gastric secretion and motality.
- (b) Oxytocin and ADH is secreted from posterior pituitary, vasopressin is another name of ADH.
- 5. (d) Adrenaline whip up metabolism to prepare animal to face special physical or mental stress. This cause contraction of spleen to squeeze out the reserve blood as well as stimulate the breakdown of liver and muscle glycogen to provide more glucose for respiration.
- 8. (d) Because thyroid gland helps in tissue differentiation and hence, in metamorphosis.
- 11. (b) Due to deficiency of ADH water absorption by kidney tubules is decreased leading to excessive urine formation i.e. diuresis, so the person feels thirsty due to dehydration.
- (b) FSH and LH are collectively known as gonadotropic hormone because they regulate the growth and functioning of gonads.
- 15. (a) The chief function of STH (GH) is to promote synthesis and secretion of small protein hormone called insulin like growth factors (IGFs).
- **17.** (b) Pancreas is a mixed gland (heterocrine gland) with both exocrine and endocrine portion.
- 18. (c) Thymus is well developed in new born child and grows upto the age of puberty after that it starts shrinking and almost disappears in old age.
- 20. (d) Thyroxine is secreted by thyroid gland.
- 21. (a) Thyroxine causes the development and differentiation of brain.

Assertion and Reason

- 1. (b)
- 2. Adrenals or suprarenals are two conical pyramid shaped glands, one immediately above each kidney. Each adrenal is made up of an outer layer called adrenal cortex and a central portion called adrenal medulla. The cortex and the medulla secrete different hormones and are regulated in different ways. Adrenal cortex is vitally important for life because it secretes a number of steroid hormones belonging to three broad groups viz. glucocorticoids, mineralocorticoids and sex corticoids. Hence its destruction or removal kills the animal. On the other hand, Adrenal medulla is not vital for surrival and may be removed without causing death. Adrenal medulla helps the body to combat against stress or emergency conditions by secreting two hormones viz. adrenaline and noradrenaline.

3. (e) It is not the adrenal cortex but the adrenal medulla which is also called the gland for 'fight, fright and flight', because the hormones secreted by adrenal medulla viz. adrenaline and noradrenaline helps the body to combat against stress or emergency conditions. Adrenaline or epinephrine dilates (widens) arterioles in the skeletal muscles and constricts (narrows) those in the skin and abdominal viscera. It increases the rate and force of heart beats and arterial blood pressure by enhancing the cardiac output. Adrenaline relaxes the smooth muscles of gastro-intestinal tract, and urinary bladder and bronchioles and contracts the sphincters of gastrointestinal tract and bladder.

increases blood sugar and blood lactic acid levels and also increases heat production, metabolic rate and body temperature. Noradrenaline or norepinephrine constricts arterioles in general or increase the total peripheral resistance against the flow of blood. The coordinated actions of both adrenaline and noradrenaline, thus help the body to react under stress conditions.

4. (d) It is not FSH (follicle stimulating hormone), but the LH (luteinizing hormone) which is also known as Interstitial Cell Stimulating Hormone (ICSH). It stimulates the interstitial cells of leydig, of testis to secrete the male sex hormone testosterone and other androgen to regulate the secondary sexual characteristics.

The follicle stimulating hormone (FSH) is secreted by anterior pituitary. It stimulates the testes in the males to produce sperms and the ovaries in the female to produce ova. It also stimulates ovaries to secrete female sex hormones called oestrogens.

- (a) The somatotropin (STH), also called growth hormone (GH) is secreted by the anterior lobe of pituitary gland. Somatotropin stimulates body growth by stimulating retention of proteins and calcium in the body, synthesis and deposition of proteins in tissues, growth and elongation of long bones, and proportionate growth of muscles and visceral organs. The failure of secretion of growth hormone from an early age stops the growth of long bones and of the body prematurely; this makes the patient dwarf and this condition is called dwarfism.
- 6. (d) A destruction of adrenal cortex by diseases like tuberculosis produces Addison's disease, due to the deficiency of glucocorticoids and mineralocorticoids which are secreted by the adrenal cortex region zona fasciculata and zona glomerulosa respectively. Symptoms of Addison's disease include a bronze-like pigmentation of skin, low blood sugar, low plasma Na+, high plasma K+, increased urinary Na+, nausea, vomiting and diarrhoea.

Cortisol is a glucocorticoid which regulates the metabolisms of carbohydrates, fats and proteins. A tumor of the adrenal cortex may secret too much cortisol to produce Cushing's syndrome.

High blood sugar, appearance of sugar in the urine, obesity, wasting of limb muscles, rise in plasma Na^+ , fall in plasma K^+ , rise in blood volume and high blood pressure are observed in the patient suffering from Cushing's syndrome.

(d) It is not oxytocin, but the hormone vasopressin (also known as antidiuretic hormone, ADH) because it reduces the volume of urine by increasing the reabsorption of water from the urine in the distal convoluted tubules, collecting tubules and collecting ducts in the kidney.

It does so by rendering the walls of those tubules permeable to water. Failure of secretion of vasopressin leads to a reduced renal reabsorption of water and a consequent elimination of a large volume of very dilute (hypotonic) urine. Oxytocin is another hormone released by the posterior lobe of pituitary gland. Oxytocin contracts the mammary glands, smooth muscles of uterus. Uterine contractions, stimulated by oxytocin at the end of pregnancy, help in the child-birth or parturition, hence also called birth hormone.

8. (d) It is not prolactin but oxytocin hormone also known as 'milk ejection hormone' because the oxytocin induces contractions of the mammary gland muscles help in the flow of stored milk from the mammary glands to the mouth of the suckling infant. Oxytocin contracts the smooth muscles of uterus and mammary glands. Uterine contractions, stimulated by oxytocin at the end of pregnancy, help in the child-birth. That is why, it is also called 'Birth hormone'.

Prolactin or lactogenic hormone or luteotrophic hormone (LTH) is secreted by the anterior pituitary which helps in the growth of mammary glands during pregnancy and initiates the secretion of milk after child-birth.

- 9. (a) The thyroid gland secretes thyroxine and triiodothyronine hormone. One of their function is stimulation of tissue differentiation. Because of this action, they promote metamorphosis of tadpoles into adult frogs. Feeding of anti-thyroid substances like thiourea to tadpoles, delays their metamorphosis. As they continue to grow without metamorphosis, they become giant tadpoles.
- 10. (c) Males have more stature than females because of the action of male sex hormone-testosterone which is secreted by testis in males. Body starts secreting testosterone from the age of puberty. Its secretion is under the influence of Luteinising Hormone (LH) of the anterior lobe of pituitary gland. Testosterone controls the development of secondary sexual characters in males like hoarseness of voice, development of facial hairs, bone growth, calcium retention, closing of epiphysial cartilage. The total quantity of bone matrix increases. The pelvic outlet is narrowed and lengthened. The strength of the pelvic bones increases to carry more loads. That is why males have more stature than females after puberty when this hormone is present in the blood.

HCG (Human Chorionic Gonadotropin) is the hormone secreted by human placenta during pregnancy. HCG enlarges the corpus luteum in the mother's ovary and stimulates it to secrete progesterone.

FT Self Evaluation Test

- The secretion of following anterior pituitary hormones is 1. controlled by hypothalamus [MP PMT 1992]
 - (a) Thyrotropin (TSH) and cortisol
 - (b) Follicle stimulating hormone (FSH) and progesterone
 - Corticotropin (ACTH), growth hormone vasopressin
 - Luteinizing hormone (LH), corticotropin (ACTH) and thyrotropin (TSH)
- 2 Which of the following hormone is not steroid
 - (a) Androgen
- (b) Aldosterone
- (c) Testosterone (d) Vasopressin 3.
- Hypersecretion of GH from pituitary in the adult causes a disease called [CPMT 2004; MH CET 2005; MP PMT 2009]
- (a) Gigantism (c) Cushing's disease
- (b) Acromegaly (d) Addison's disease
- The nervous control of pituitary secretion lies in
 - (a) Infundibulum
- (b) Pituitary centre
- (c) Hypothalamus (d) Medulla oblongata The hormone responsible for the regulation of metabolism 5. of calcium and phosphorus is secreted by
 - (a) Thyroid (b) Parathyroid and thyroid both
 - Thymus
 - (d) Pancreas
- The hormone which controls the rate of body metabolism is
 - [CBSE PMT 1993; RPMT 2006] (a) Thyroxin (b) Insulin
- (c) ACTH 7.
- Hypothyroidism causes
- HGH

(d)

- (a) Myxodema (c) Both (a) and (b)
- (b) Cretinism (d) Exophthalmic goitre

[DPMT 2007]

- A person is having problems with calcium and phosphorus metabolism in his body. Which one of the following glands may not be functioning properly [CBSE PMT 2007]
 - Parathyroid
- (b) Parotid (d) Thyroid
- Pancreas 9. Epinepherine is

 - (a) Nephrostomal part of mesoderm (b) Clusters of glomeruli in mammalian kidney
 - (c) Hormone of the adrenal gland
 - (d) Frontal lobe of nephridia
- 10. A steroid hormone which regulates glucose metabolism is [CBSE PMT 2006]

Excess of which of the following hormones causes Cushing's syndrome [AFMC 2009]

- (a) 11-deoxycorticosterone (b) Cortisone
- (c) Cortisol

- (d) Corticosterone [CPMT 2009]
- 11. Prostaglandins are
 - (a) Amino acid (b) Steroid
 - (c) Fatty acid
- (d) Carbohydrate
- 12 Which of the endocrine gland is mainly concerned with
- immunity in man [CPMT 1994; MP PMT 1994, 99; Odisha JEE 2010]
 - (a) Parathyroid gland
- (b) Adrenal gland
- (c) Thymus gland The pancreas secretes
- Posterior pituitary gland [MP PMT 2013]
- (a) Pancreozymin

13.

(b) Angiotensin I (c) Somatostatin (d) Angiotensin II Column I lists the endocrine structure and column II lists the corresponding hormones. Match the two columns. Identify the correct option from those given

Column I

- Column II Hypothalamus Relaxin Estrogen
- B. Anterior pituitary Testis D. Ovary
- FSH and LH S
- Androgens
 - Gonadotropin releasing hormone

[Pb PMT 2000; KCET 2000, 06; JIPMER 2001; BHU 2005; MP PMT 2012]

- (a) A=t, B=r, C=s, D=q (b) A=t, B=r, C=q, D=s (d) A=r, B=t, C=s, D=q A=p, B=q, C=s, D=r
- 15. Match the hormone in column I with their function in column II
 - Column I Column II A. **FSH** Prepare endometrium for implantation B. 2. Develops female secondary sexual characters C Progesterone 3. Contraction of uterine wall D.
 - Estrogen 4. Development of corpus luteum 5. Maturation of graffian follicle
 - [Kerala PMT 2006] (b) A-4, B-5, C-2, D-1 (d) A-5, B-1, C-2, D-4 (a) A-5, B-4, C-1, D-2 A-4, B-3, C-2, D-5 A-4, B-2, C-3, D-5

Answers and Solutions

1	d	2	d	3	b	4	С	5	b
6	a	7	C	8	a	9	С	10	C
11	C	12	С	13	C	14	a	15	a

- Hypothalamus secretes both releasing and inhibitory 1. hormones controlling the secretion of some anterior pituitary hormones (LH, ACTH, and TSH etc.) 3.
- Hypersecretion of growth hormones or somatotrophic hormone during adulthood causes acromegaly. Acromegaly patient has a gorilla like appearance with huge hands and legs.
- 4. Hypothalamus synthesizes and secretes certain specific chemicals called factors which pass to adenohypophysis to control secretion of its hormones, thereby called master of masterglands.
- Parathyroid and thyroid hormones regulates the amount of 5. calcium and phosphate in extra cellular fluid. It promotes the absorption of calcium from food in intestine, it accelerates elimination of phosphates in urine.
- (a) Thyroxine's main function is to control the BMR-6. metabolism. These help in homeothermy in warm blooded animals.
- The chromaffin cells of adrenal medulla synthesize two hormones adrenaline or epinephrine (80%) and noradrenaline or norepinephrine (20%).
- 12. Thymus is the site of differentiation of T-lymphocytes of immunity system.
